

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

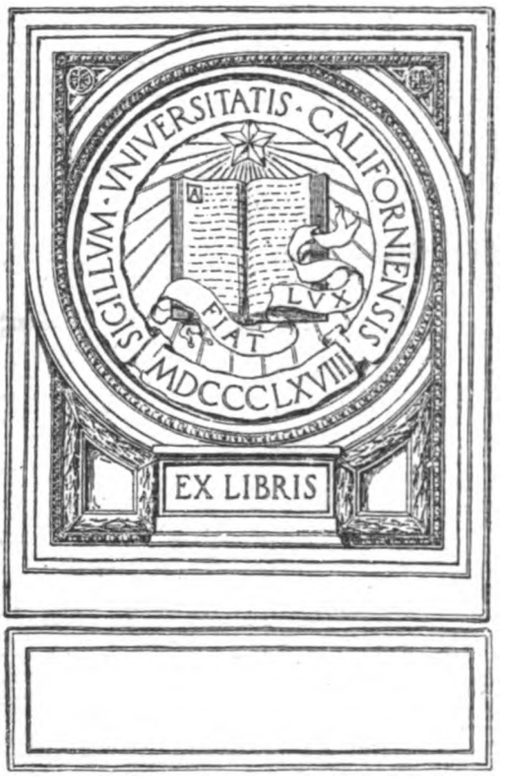
Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

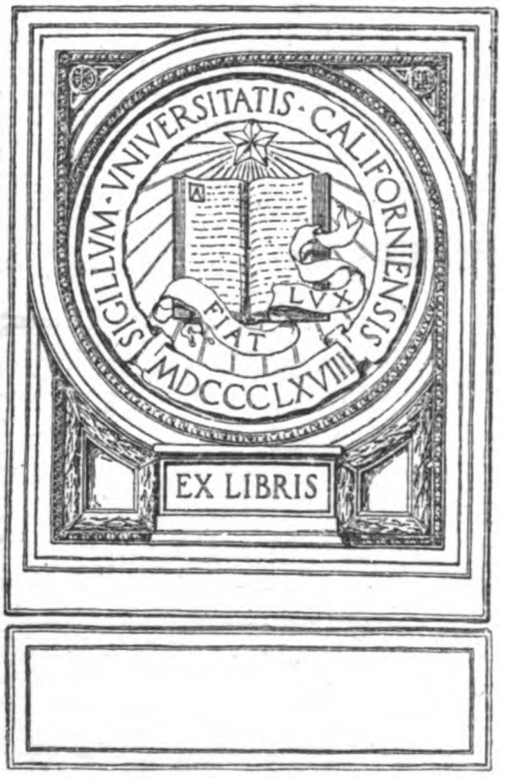
+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.



+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search



Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

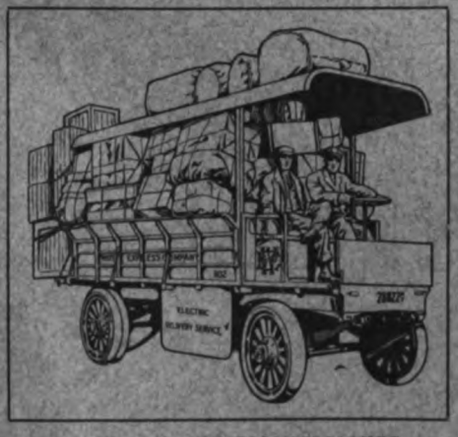
The MOTOR TRUCK

Devoted to Motor Driven Business Vehicles of All Classes.

Vol. III Pawtucket, R. I., January, 1912. N.S.E. No. 1

Who Sells the Fleets?



TRADE GENERAL VEHICLE GREATEST VALUE MARK

LIBRARY OF THE UNIVERSITY OF CALIFORNIA

The General Vehicle Company has nearly 40% of its output, or over one thousand (1000) G. V. Electrics divided among one hundred customers. Twenty of these customers operate an average of 29.2 G. V.'s each.

Over one million dollars ($1,000,000) worth of G. V. Electrics are used in brewery transportation service alone.

We have been building electric trucks and wagons since 1901 and many of the vehicles referred to above are from six to ten years old.

A G. V. 3 1-2 TON MONEY MAKER

These facts may upset your preconceived ideas of motor truck adaptability but a great many intelligent men will learn in the next few years that the electric truck—and particularly the G. V. Electric—is the best truck for 80 per cent. of all transfers and deliveries.

The G. V. Electric has the lowest maintenance cost of any power vehicle.

This because it is simple in construction and operation—economical as to power and has great durability.

Furthermore, all six G. V. models are standardized and all parts of each model are interchangeable and readily accessible.

Made in the following capacities: 750 lbs., 1000 lbs., 2000 lbs., 2 ton, 3 1-2 ton and 5 ton.

Catalog No. 80 and Other Data on Request

You will find us at the Madison Square Show, New York, January 15-20, with at least ten vehicles. Also at the Chicago Show, February 3-10, 1912.

COMPLETE INSTALLATIONS — GASOLINE — GMC — General Motors Company — TRUCKS — ELECTRIC — COMPLETE SERVICE

At the Madison Square Show

New York, January 15-20

and at the Chicago and Boston Shows

GASOLINE TRUCK—BREWERY BODY
Model K—5 Ton Capacity. Price, Chassis Only, $4400

ELECTRIC TRUCK—EXPRESS BODY
Model 3—3000 lbs. Capacity. Price, $1700, Chassis Alone, Batteries and Bodies Optional.

The prospective buyer of motor trucks cannot afford to consider a truck apart from the company that makes and sells it. If he is to get the maximum number of years' use from a truck—if he is to get the highest efficiency and the greatest economy in operation during those years—after the purchase must come service.

The G M C is the mark, not of a car, but of a company. G M C trucks have behind them the manufacturing facilities, the engineering and operating experience, and the financial permanence of the General Motors Truck Company—your banker will tell you what that means.

G M C service is a distinct department of the organization under a General Service Manager. The policy of this Service Department will be to insure to the purchaser a prompt service at times of emergency—in parts, personal assistance and co-operation.

Where it is desired, a special service will be rendered, before a sale is made, in a thorough analysis and study of any delivery or hauling requirements.

If you would build up a standardized delivery system, and have each truck a harmonious unit in the whole, select trucks built by a manufacturer who will be able to fill your future as well as your present requirements.

The G M C line includes gasoline and electric trucks in capacities of 1000 pounds to 6 tons.

Inspection of our exhibits at the New York, Chicago and Boston Commercial Car Shows is invited, as is correspondence from prospective purchasers and dealers.

VOL. III. PAWTUCKET, R. I., JANUARY, 1912 No. 1

TWO NATIONAL TRUCK SHOWS IN NEW YORK.

Commercial Vehicle Display in Madison Square Garden Follows Week Devoted to Pleasure Cars---Power Wagons Share Interest at Grand Central Palace---Accessories to Be Seen at Both Exhibits.

AT NO time in the history of the automobile industry have so many differing makes of commercial motor vehicles been assembled for the inspection of the business man as will be true during the two national shows in New York City this month. Considered in its broadest application, this means that never before has the prospective purchaser of power wagons had such opportunity to study the various offerings side by side, with every possibility of determining their respective merits. This, in itself, should be sufficient reason why the modern business man should make every endeavor to visit the metropolis during these displays. Fortunately, those responsible for the success of the exhibitions have so arranged their dates that this unparalleled array of models in the two largest buildings of the city will be open for inspection at the same time.

To put the matter in more concrete terms, it should be noted that during the National Association of Automobile Manufacturers' show in the Grand Central Palace, Jan. 10-17, and the Automobile Board of Trade's display in Madison Square Garden, Jan. 15-20, there will be seen at least 66 different makes. This figure is based upon the reports now at hand, but as is usually true, there is every possibility that this number will be increased at the last moment. That this is the largest showing of commercial vehicles ever made is based upon the fact that the most comprehensive previous display was that during the second week of the Chicago show last year, when 57 manufacturers were represented. Something over 40 were to be seen at the 1911 Boston show, and this exceeded the number displayed at New York City last January.

Madison Square Garden, New York City, Looking from the 26th Street and Fourth Avenue Corner, Where the Automobile Board of Trade Shows Will Take Place Jan. 6-20.

It may be mentioned that the exhibits of accessories at the forthcoming New York shows also will set a new record, 363 firms as against 304 for Chicago, and 320 for New York in 1911. The 11th hour additions in this field always are much larger than with the vehicles, and it seems safe to predict that the total will reach very close to 400. As many of these supplies, parts and fittings, have a direct interest to the motor truck owners and users, it is anticipated that the accessory booths will prove quite as attractive to the business men as any other portion of the exhibitions.

While it may be considered that those directly concerned with power wagons will be less interested in the pleasure vehicles, it is worthy of note that the two New York shows will present at least 93 different makes of these. This number is but one behind that seen during the first week at Chicago last year, and exceeds the Madison Square Garden showing of 1911 by 23. The pleasure car show at the Garden this year will be held Jan. 6-13, while these types will share interest with commercial vehicles at the Grand Central Palace Jan. 10-17.

Thus it will be seen, that beginning with Jan. 6 and continuing until Jan. 20, ample opportunity will be afforded to study the best productions of American manufacturers in all lines. For those who desire to devote the greater portion of their time to motor trucks, it is possible to reach the city during the latter part of the first week, comparing the offerings of pleasure cars at Madison Square Garden and the Grand Central Palace, and remain over Sunday to complete the inspection of power wagons during the early portion of the second week.

In one sense the Grand Central Palace exhibition is an overflow from Madison Square Garden. There is no rivalry between the National Association of Automobile Manufacturers and the Automobile Board of Trade, at least not in the same sense which has marked previous displays in New York. Samuel A. Miles, general manager of the former organization, has worked in conjunction with the show committee of the latter with a view to presenting the most representative showing of cars, trucks and

246523

Digitized by Google

accessories possible. His 10 years' experience in managing the Chicago shows, as well as in assisting others in various sections of the country, is sufficient guarantee of success.

The new Grand Central Palace, which will house its first automobile show in this exhibition, is a 13-story structure on Lexington avenue, two blocks north of the old building of that name. The three exhibition floors are particularly fitting to an admirable architectural creation. The show space is a colonnade with gallery for the first and second floors, and the third floor also is in the nature of a gallery, the great central court of the second floor being contracted to half its size at this point, the floors being supported by pairs of massive columns on single pedestals. There is less need of decoration than were it a single arena, and the vehicles will be more prominent relatively.

Twenty-eight different makes of pleasure vehicles and two of service wagons will be seen on the first floor. Six makes of pleasure cars and 35 of motor trucks will be shown on the second. The latter will include everything from the small package delivery wagon to the heaviest truck, and with an almost endless variety of body constructions. Accessories will be displayed on both the second and third floors.

Of the manufacturers who will be represented at this show, it is stated that no less than 35 makers of cars made no display in the metropolis last year, and a large proportion will exhibit for the first time at any show. It hardly is necessary to point out that these exhibits will prove quite as interesting as those made by better known constructors.

The Madison Square Garden display is in charge of Col. George Pope, Alfred Reeves and Merle L. Downs, representing the Automobile Board of Trade. All of these men have been identified with automobile shows in this building for years, and there can be little doubt that they have exerted themselves to produce results which shall be even more successful in every particular than at previous events.

New Grand Central Palace, Lexington Avenue and Depew Place, Where the Show of the National Association of Automobile Manufacturers Will Take Place Jan. 10-17.

It is fitting that the display of machines shall have a setting of especial dignity, and yet it must be appropriate to the two divisions, the one for pleasure cars and the other for commercial vehicles. The decorations will be quite in keeping with this view, as indicated by an accompanying illustration. Vehicles will be shown on the main floor and two balconies, as was the case last year, while accessories will be found in the basement and on each of the floors other than the main floor. Motorcycles will be shown in connection with pleasure vehicles during the first week.

Promptly at 11 on the evening of Jan. 13, the pleasure car division will come to an end, and immediately thereafter the exhibitors will begin the work of removing their cars. This applies only to automobiles and motorcycles, since nearly all of the accessory makers will continue their display through the second week. The plan is the same as that adopted last year, and it is anticipated that there will be no delay in preparing the building for the second division, in which trucks will be the prominent feature.

The truck exhibit will open at 10 in the morning of Jan. 15. Most of these vehicles will be housed on the main floor, although the so-called elevated platform will be reserved for some of the lighter wagons and electrics. This will mean that it will be necessary to visit both floors in order to study all the business automobiles. The showing will be equally as complete as that during the first week, and there will be nothing to detract from the nature of the display.

With respect to the display of power wagons during the second week at Madison Square Garden, it should be said that there will be 26 makes of gasoline vehicles and six electrics. This statement is made having in mind the information now at hand. Inasmuch as there are yet some two weeks before the show is scheduled to open there is time for the addition of other models. It is remembered in this connection that two of the best known manufacturers entered exhibits at the last moment in 1911. At least three of the business vehicles have not been shown at previous displays. Inasmuch as the matter of body design has attracted no little attention in the motor truck field during the past few months, it is expected that the various manufacturers will devote rather more thought to this detail than in past years. Information at hand concerning both exhibits leads to the conclusion that considerable effort will be made toward the presentation of types for special lines. And it is practically certain that much can be learned concerning the possibility of adapting the various chassis shown for individual purposes. It is not probable that the manufacturers would allow the opportunity to pass for a careful study of this feature, and the business man who has special requirements in this line undoubtedly will find abundant means of acquiring knowledge of this subject.

In short, the practicability of the power wagon having been established the industry has reached a point where it is possible to devote much attention to the details of refinement in construction and design necessary to meet the varying needs of the user. The 66 makes on display in New York City this month will represent the best productions of American engineering. This applies with equal force to both commercial and pleasure vehicles, and may also be said to hold true with reference to accessories, parts, fittings and supplies.

On the following pages is presented a detailed list of the exhibitors at both buildings. This not only indicates where each make of truck may be found, but the pleasure cars as well. The accessories have been classified according to the various lines, making it possible for the visitor to lay his plans for inspecting that which he desires to see, before leaving home. In this connection the diagrams of floor spaces should prove most helpful. It will be noted that the various makes of cars and lines of accessories have been arranged in alphabetical order. It is believed that this plan will be thoroughly appreciated.

EXHIBITORS AT BUFFALO'S FIRST DISPLAY.

THE dealers in Buffalo, N. Y., are to have two shows this year, one of which opened in the 74th Regiment armory, Dec. 30, and will continue until Jan. 6. The second, which was thought to be necessary, because this building, though even larger than ever before, was unable to accomodate all who desired to make display, will be held Feb. 5-12. The exhibitors at the first show follow:

Commercial vehicles—Henry Brunn Automobile Co., Peerless; Empire State General Vehicle Company, General Vehicle; George Ostendorf, Franklin; A. W. Meyer Motor Car Company, Knox and Reo; United Motor Buffalo Company, Sampson; Mason B. Hatch, Stearns; Pierce-Arrow Motor Car Company, Pierce-Arrow; Dixon Motor Car Company, Velie; Sanderson & Burghardt Company, Speedwell; Co-Operative Motor Car Company, Pope-Hartford and Mack; Buick Motor Company, Buick; Lutz Automobile Company, White; Louis Engel, Jr., Cartercar; Densmore Company, Packard; Studebaker Corporation, Studebaker; Werick Bros. Motor Car Company, McIntyre and Schacht; Barret Motor Car Company, Kelly; Overland-Buffalo Company, Overland and Garford; Buffalo Kissel Kar Company, Kissel Kar; Anderson Electric Car Company, Detroit electric; Hays-Schoeplin Company, Rapid and Reliance; Lippard-Stewart Motor Car Company, Lippard-Stewart.

Pleasure cars—J. I. Case Threshing Machine Company, Case; Henry Brunn Automobile Co., Peerless; John J. Gibson Company, Mitchell; George Ostendorf, Franklin; Ralph E. Brown Motor Car Company, American, Babcock and Winton; A. W. Meyer Motor Car Company, Knox, Reo and Pullman; United Motor Buffalo Company, Columbia, Maxwell; J. A. Cramer, Stoddard-Dayton; Mason B. Hatch, Chalmers, Hupmobile and Stearns; Pierce-Arrow Motor Car Company, Pierce-Arrow; E. R. Thomas Motor Car Company, Thomas; Dixon Motor Car Company, Herreshoff and Velie; Sanderson & Burghardt Company, Firestone-Columbus, Havers and Speedwell; Co-Operative Motor Car Company, Abbott-Detroit, Pope-Hartford and Stevens-Duryea: Poppenberg Motor Car Company, Paige-Detroit, Warren and Everitt; Albert Poppenberg, Apperson, Clark and Westcott; Buick Motor Company, Buick; Lutz Automobile Company, White and Premier; Louis Engel, Jr., Cartercar; Babcock Electric Company, Babcock; Matheson Automobile Sales Company, De Tamble and Union; K-R-I-T Motor Car Company, K-R-I-T; Windsor Motor Car Company, Elmore and Kline-Kar; Densmore Company, Packard; Centaur Motor Company, Oakland; Studebaker Corporation, E-M-F and Flanders; Frontier Motor Car Company, McFarlan; Werick Bros. Motor Car Company, Haynes, McIntyre and Schacht; Zimmer Motor Vehicle Company, National; Fiat Sales Company, Fiat; Edgar Messersmith, Lexington and Whiting; Barret Motor Car Company, Hudson; Baker Bros. Motor Car Company, Cole and Nyberg; Olds Motor Works, Oldsmobile; Delaware Ave. Garage, Marmon; Hupp Corporation, R. C. H. and Hupp-Yeats; F. A. Ballou, Brush, Jackson and Selden; Overland-Buffalo Company, Overland and Garford; Buffalo Kissel Kar Company, Kissel Kar and Simplex.

Accessories—Standard Oil Company, Polarine oils; Brunn & Co., tops and bodies; Polson Manufacturing Company, windshields; Jaynes Automobile Supply Company, general line; Frey Automobile Supply Company, De Luxe overhead washers; Iroquois Rubber Company, G & J tires; Frontier Rubber Company, Frontier tires; Chas. E. Miller, full line; Niagara Lead & Battery Company, Salom batteries.

DENVER SHOW EXHIBITORS.

While the Denver automobile show is still some distance away, being scheduled for March 4-10, not a little interest has been awakened in the commercial vehicles which will be displayed. Practically every agency in the city will be represented, and it is anticipated that a number from other sections of the Southwest will secure space if possible. Among those who will show business vehicles are the following:

W. W. Barnett, Alco; Overland Automobile Company, Brush, Kissel-Kar, Overland, Seitz; MacFarland Automobile Company, Buick, Packard; Timpte Bros. Wagon Company, Chase; Continental Motor Truck Company, Continental; Havens Bros. Motor Company, Dorris, Kelly; Colorado Motor Sales Company, Grabowsky; Mathewson Automobile Company, Reo; Fernald Automobile Company, Sampson; Mead Autocycle Company, White; Krebs-Gotshall Automobile Company, Detroit electric; Carstarphen Electric Company, General Vehicle electric; Felker Automobile Company, Waverley electric.

WILL SELL PEERLESS TRUCKS.

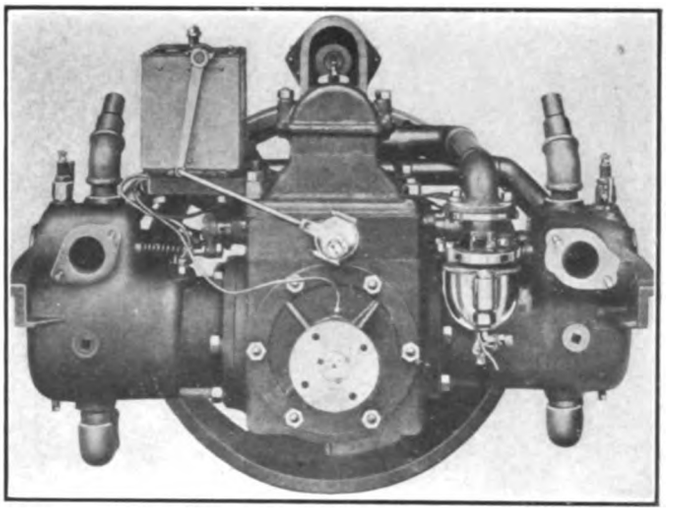
R. S. de Mitkiewicz, formerly sales engineer with the Motor Engineering & Sales Company of New York City, has resigned to accept a position with the truck department of the Peerless Motor Company of New York, at 1760 Broadway and 57th street. His headquarters will be at that address, but he will occupy his time in placing Peerless trucks, made by the Peerless Motor Car Company, Cleveland, O., in the East.

Digitized by Google

TREND OF DESIGN IN COMMERCIAL CARS.

Rapid Progress Noted in Development of Practical Power Wagon---Simplicity and Accessibility Features of New Models Ranging from Light Delivery to Heavy Truck.

BELIEVING that there is a demand for a commercial vehicle of 1000 to 1500 pounds carrying capacity, the Sullivan Motor Car Company, Rochester, N. Y., is manufacturing and marketing a chassis to which is fitted several types of bodies, these being designed principally for delivery work. The same chassis is utilized for all models, its sturdy construction permitting of this arrangement, and being well powered is capable of taking care of reasonable overload.

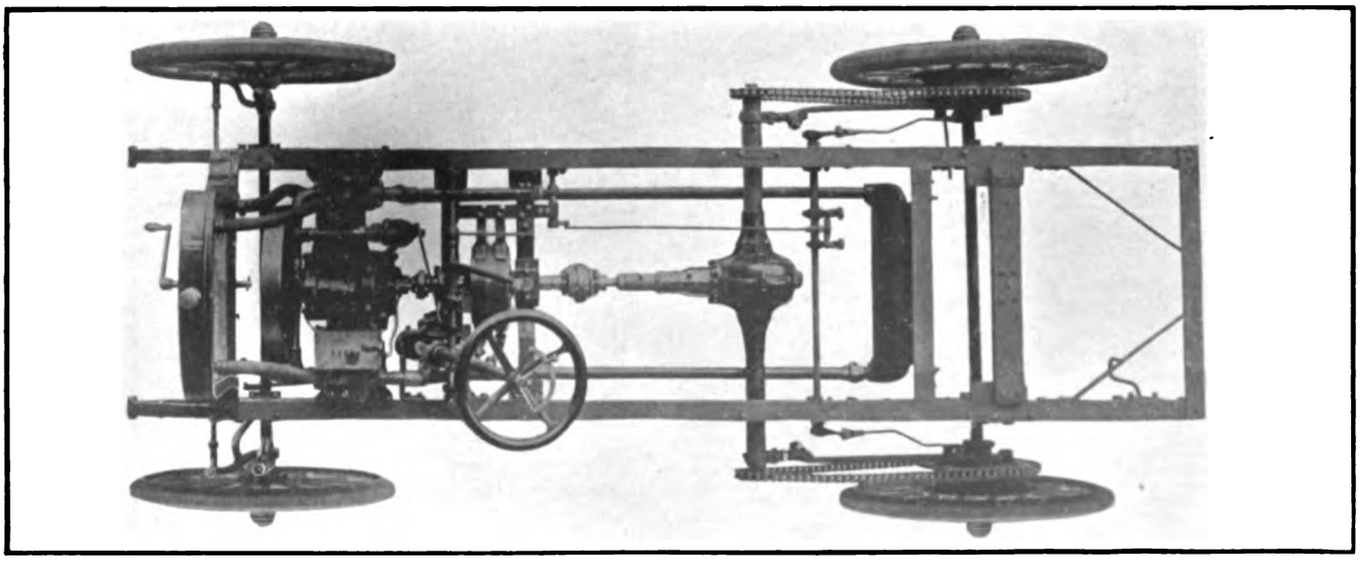


The motor is located in front and the arrangement of the power plant is very compact as well as easily accessible, being reached by the lifting of the usual bonnet. It is a two-cylinder, four-cycle, water-cooled unit, with a 4.5-inch bore and stroke and rated at 18 horsepower, being of the horizontal double-opposed type, and the cylinders are cast singly with liberal water jackets, these being cast integral therewith. The cylinders are machined and ground carefully, as are the pistons and rings, insuring good compression.

The connecting rod, main and camshaft bearings are of ample dimensions, these being reached easily by the removal of the top section of the crankcase on which is fitted the magneto. The crankshaft is 1.75 inches with bearings 3.8125 inches. The connecting rod bearings are 1.75 inches. A Schebler carburetor is fitted, this being located on the right hand side of the motor, well protected from dirt and possible injury, and the intake pipes leading to the cylinders are well designed and free from sharp bends, thus facilitating the passage of the mixture.

The five-feed mechanically operated oiler is carried on an extension of the upper crankcase on the left hand side of the motor and is positive in its action. Cooling is by the thermo-syphon system, the water pipes being of liberal size. The radiator is located in front and cooling is aided by blades in the flywheel of the engine. Ignition is by a Bosch high-tension magneto.

An improved planetary transmission is fitted and energy is transmitted to the driving shaft by another shaft carrying a dust and oil-tight universal joint. Brown-Lipe gears are utilized in the differential, and Hyatt roller bearings and ball thrusts in driving shaft. Final drive is by side chain and the sprockets are adjustable and detachable. Internal expanding, 10 by 2.5-inch brakes, are fitted to the rear wheels and are positive in action, this being brought about by an equalizer. These members are easily reached and adjusted.

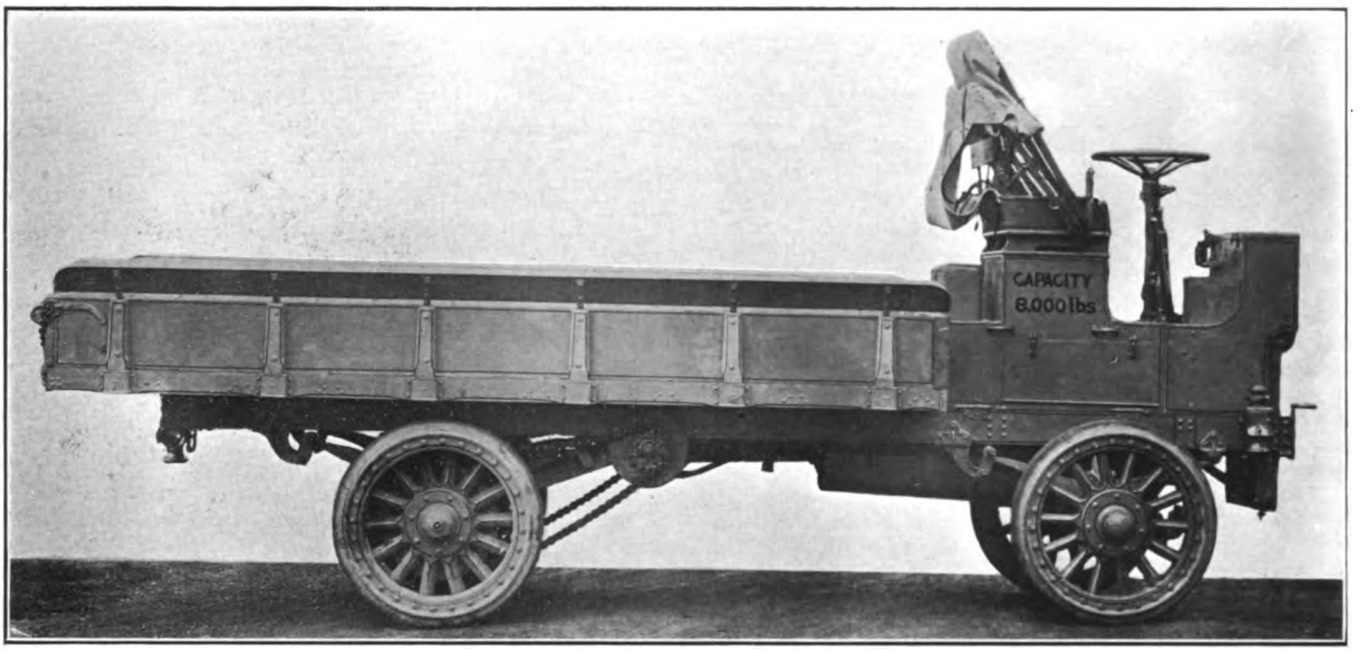


The frame is of liberal dimensions and all sections including cross members are hot riveted. Steering is by the

Power Plant, Showing Compact Arrangement of Components.

usual wheel and the control of gas is by lever mounted thereon. The driver's position is at the left with centre control. The front axle is 1.375 inches and rear 1.75. Full elliptic springs are employed both front and rear, those of the former being half-scroll and the latter full. Solid tires are fitted, 36 by 2.5 inches.

The design of the frame is such that a long overhang body may be fitted as will be noted in the accompanying illustration. This section of the frame is strongly reinforced by two large cross members. This arrangement permits of the fitting of a body of the express type and that made by the company is 72 inches long and 42 inches wide. A full wood panel body is also fitted to the same chassis and is made of ash frame work and heavy sills with bevel plate glass doors in rear and windows in side. This type of body is unusually neat and attractive in appearance, is highly finished and especially adapted to delivery work.

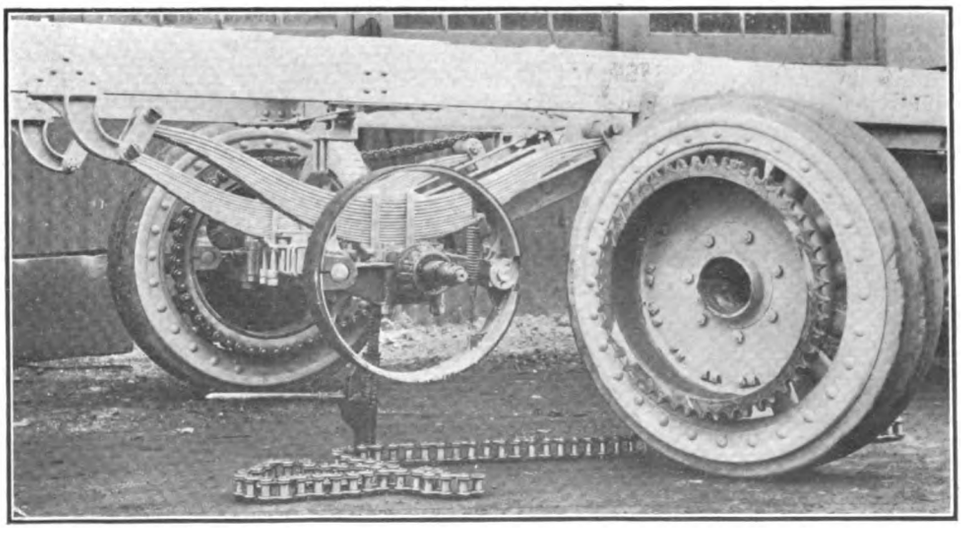


Chassis of Sullivan Car Which Is Fitted with Horizontal Double Opposed Motor Located in Front and Easily Accessible.

Digitized by Google

SPEEDWELL PRODUCT INCLUDES LARGER TRUCKS.

SPEEDWELL commercial vehicles, manufactured by the Speedwell Motor Car Company, Dayton, O., maker of the well known pleasure cars of that name, include in addition to ambulances, patrols and other automobiles designed for municipal service, two machines of four and six tons capacity, respectively. These are said to include features not found on any other make of power wagon, although in the main they follow standard lines of construction. The four-ton truck, which is illustrated herewith, is built in two lengths of wheelbase, 115 and 139 inches, and although a wide variety of bodies is fitted, special types may be procured from the company.



Four-Ton Speedwell Fitted with Standard Sideboard Body, Including Folding Top, Storm Front and Curtains.

The motor is located in front, under the floorboards of the driver's seat, and is easily accessible for minor adjustments by removable panels. The framework of the seat is hinged and by removing bolts may be raised at either side, a commendable arrangement, and one that uncovers the entire driving mechanism.

The chassis has a four-cylinder, four-cycle, water-cooled motor with a five-inch bore and stroke and is rated by the maker at 40 horsepower at 1000 revolutions a minute, which represents the maximum at which the vehicle should be run, 12 miles an hour. The cylinders are cast in pairs with integral water jackets, and are of the L type.

A Schebler, water jacketed carburetor is incorporated, the feed being gravity from a 19-gallon tank over the radiator. Ignition is by a high-tension Eisemann magneto with automatic spark advance. As the motor will start by cranking with this member, no battery system is fitted. Lubrication is by the splash system, a gear driven pump forcing the oil through a sight feed on dash to the crankcase where a constant level is maintained. A cellular radiator, suspended on double coil springs, is provided and the water is circulated by a centrifugal pump and cooling assisted by a belt driven fan.

The clutch is cone, leather faced. A selective type of transmission, affording three speeds forward and a reverse, is controlled by a single lever located in the centre of the footboard and at the right of the operator. Drive is by shaft to jackshaft, in which the differential is housed, and by sprockets and side chains of ample dimensions to the rear wheels. A differential device is fitted for the purpose of securing traction by both wheels, this being brought about by locking. This is operated by a lever which extends through the sides of the main frame.

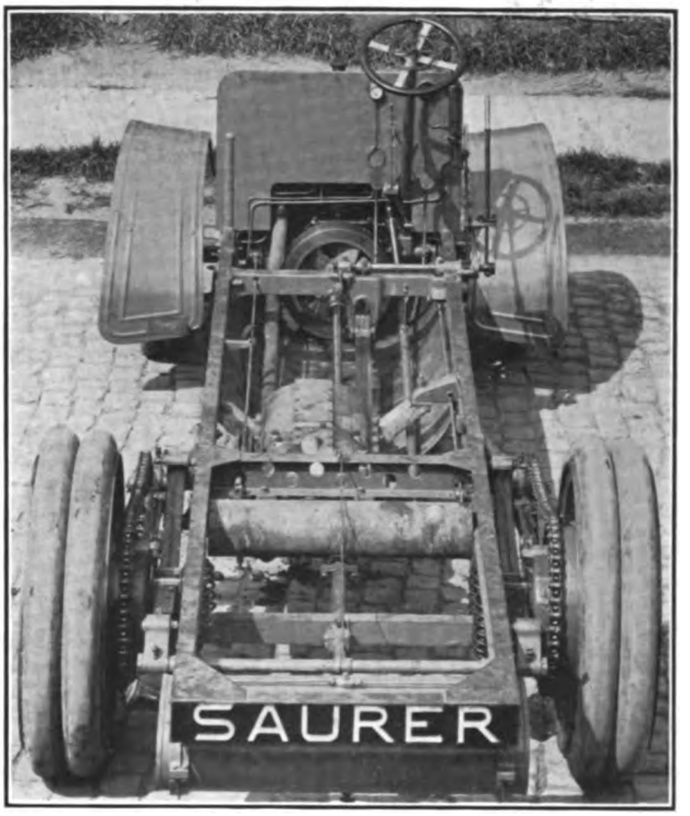
Showing Construction of Rear Wheel Brakes, Springs, and Auxiliary Spring Member.

Semi-elliptic springs are fitted both front and rear, the former being 40 by three inches, and the latter 48 by three. An auxiliary member is hung from a cross member on the frame and bearing upon plates mounted on the rear axle comes into operation only when the truck is loaded nearly to its full capacity. The front axle is of the solid I beam section type, ample in size as is the rear member. The front and rear wheels are mounted with Timken roller bearings and both these members are 36 inches fitted with five-inch solid tires, single in front and dual at the rear. Two sets of brakes are provided.

Digitized by Google

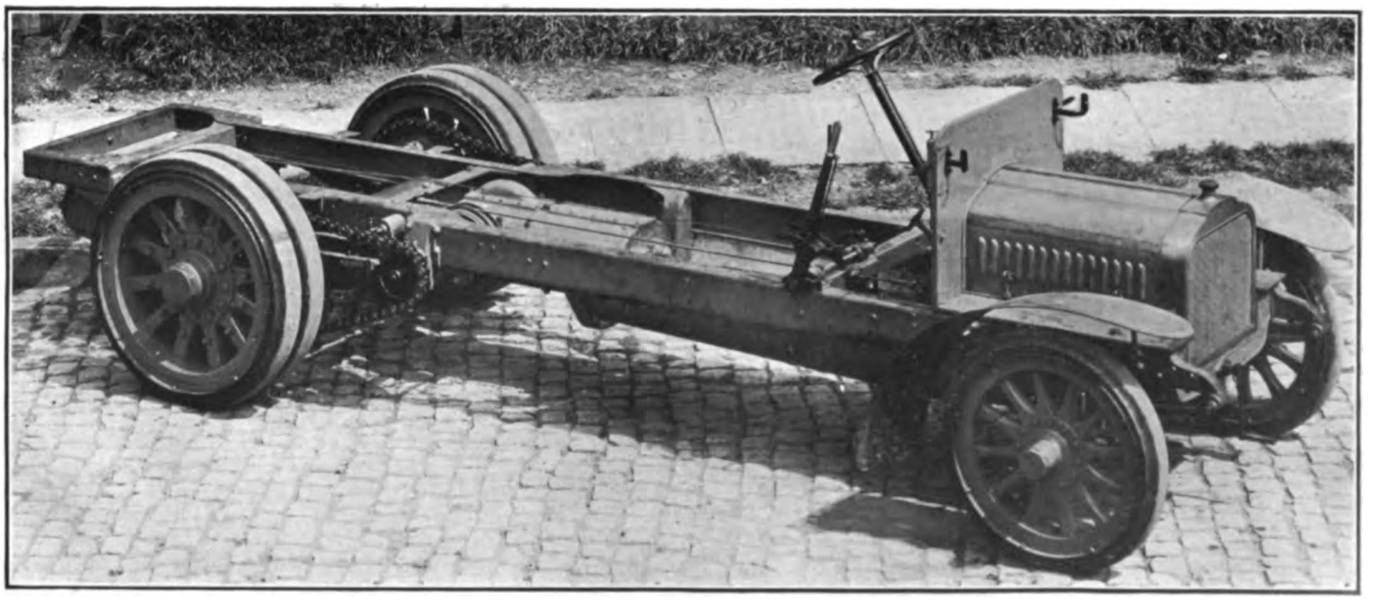
SAURER TRUCK PRESENTS STURDY CONSTRUCTION.

SAURER trucks, the chassis of the 4.5 and 6.5-ton sizes of which are shown herewith, are manufactured under license in this country by the Saurer Motor Company, Plainfield, N. J., a constituent of the International Motor Company, New York City. The Swiss product enjoys an enviable reputation, having won 53 first prizes in European contests, and the recently completed Ocean-to-Ocean trip of 5200 miles in America, which was finished without a mechanical or structural defect being brought out, gives some idea of the car's reliability.



Three special, patented mechanical features, each desirable, mark this design. They are: The Economy carburetor, the air brake and the self-starter. The first named has two nozzles, the operation of which is controlled by an automatic clock valve. One jet is constantly in use, the second being brought into play when the speed of the motor reaches a certain point. The self-starter is on the compressed air principle.

The motors fitted to the 4.5 and 6.5-ton trucks are four-cylinder, four-cycle, water-cooled, with cylinders cast in pairs. The valves are on the opposite sides, of nickel steel and of liberal dimensions. The motor is rated at 37 horsepower at 1000 revolutions, having a 4.375-inch bore and 5.75-inch stroke. Crank, cam and fanshafts are mounted on imported ball bearings, of large diameter, and all are of the finest chrome-nickel steel. In machining and assembling, special care has been given to the matter of correct balance, both running and static, this resulting in a quiet, powerful motor.

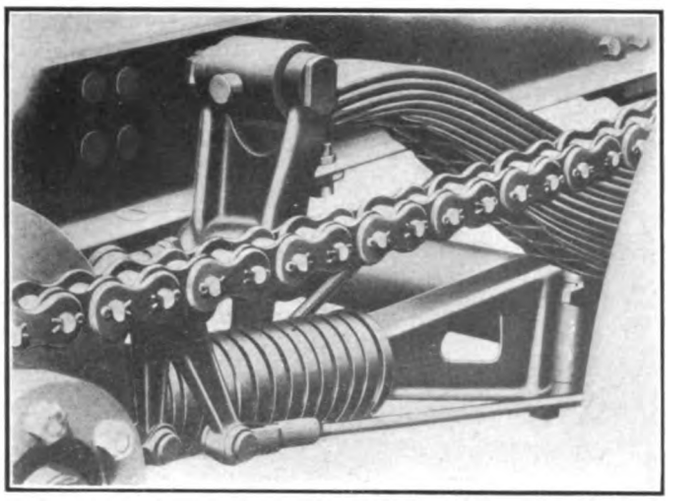


Lubrication is of the forced feed type with gear inside the oil tank and driven from the governor shaft by spiral gears. Cooling is by water, actuated by a centrifugal pump, easily accessible. Ignition is a high-tension magneto with spark advance lever on the dash, and is advanced or retarded by means of a sleeve on the driving shaft. The motor is controlled through a governor of the centrifugal ball type, this being restricted by a spiral spring. A cone clutch is used, leather faced with a rubber ring below it. The spring pressure is such as to give easy engagement and release. A four-speed transmission is utilized, the gears of which are of nickel steel and the shafts are mounted on annular ball bearings, with thrusts for lateral stresses. The differential gear, of the four-pinion bevel type, is mounted in the gearcase. The jackshaft is of chrome-nickel steel mounted on ball and thrust bearings.

Three sets of brakes are provided; the air form, which the driver operates by a short lever on the dash; the usual contracting band on the differential shaft operated by pedal, and the internal expanding in the rear wheels. The axles are of special drop forged steel, of large section.

The wheels, which run on roller bearings, are ample in size, and are fitted with solid tires, single in front and dual in the rear. Those of the 4.5-ton are equipped with 36 by five inches front and 42 by five inches rear. The rear wheels of larger chassis have 5.5-inch tires. The weight of the smaller chassis is 5700 pounds while that of the larger model is 6900. The wheelbases are 153 and 159 inches.

Chassis of 4.5-Ton Saurer Truck, Illustrating the Sturdy Construction of Frame and Cross Members and Low Centre of Gravity.



Depicting Special Inside Rear Spring Construction and Straight Line Drive on 6.5-Ton Model.

Digitized by Google

VELIE LINE CONSISTS OF THREE MODELS.

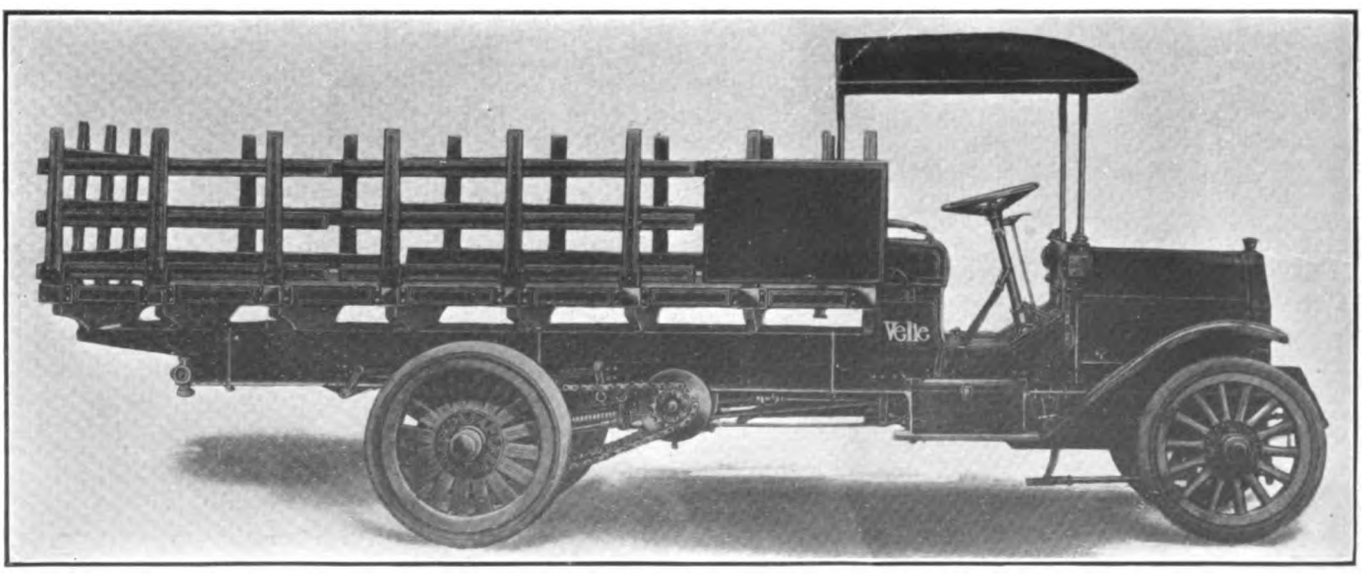
VELIE commercial vehicles, made by the Velie Motor Vehicle Company, Moline, Ill., consist of three models, 1500-pound, 1.5 and three-ton, respectively. Every working part is easily accessible, facilitating inspection. The

Showing Velie Spring Strut Rod and Outside Spring Suspension.

design is such that the weight of the load is evenly distributed permitting of lighter spring suspension at the front axle thus protecting the power plant from road shocks and vibration. Among other features are: A heavier frame, larger wheels and tires, spring strut rods, differential lock, large rear axle, and means for driving a loading winch.

The chassis is a complete unit in itself to which may be attached any standard, optional or special body, and is made in two lengths of wheelbase, of 142 or 178 inches in the three-ton size, permitting of carrying receptacles suitable for any requirements. The chassis may be turned in a 50-foot circle. The weight of the longer member is 6000 pounds, and that of the smaller, 5550. The regular stake body, such as shown in the accompanying illustration, weighs 1000 pounds.

The motor, which is located in front, is a four-cylinder, four-cycle, water-cooled type with a 4.5-inch bore and 5.25-inch stroke. The cylinders are cast in pairs with integral water jackets. The water is circulated by a large centrifugal pump on the right hand side of the engine, and the radiator is suspended upon a spring cushioned saddle to absorb road shocks. Cooling is aided by a belt driven adjustable fan. A splash system of lubrication is employed and a constant level in the crankcase is maintained by a pump. A sight feed is fitted to the dash and the reservoir is of six quarts capacity. Ignition is by a Splitdorf magneto which is independent of the auxiliary, consisting of batteries and the Atwater Kent system. The spark and throttle levers are mounted on the steering wheel and provide control up to a rate of 12 miles an hour. An automatic governor prevents a greater speed, this member being sealed in a case to prevent the operator changing its adjustment.



A three-plate disc clutch is utilized and is fitted with an automatic clutch brake. The selective sliding gear transmission, which provides three speeds forward and a reverse, and the extra heavy gears and shafts are made of nickel steel, mounted on Timken bearings and have a 1.5-inch face. The jackshaft and differential also are sturdily constructed and carried in a separate housing from the transmission. The differential gear is 15 inches in diameter and the entire assembly is mounted on Timken bearings. A double Spicer universal joint drive is employed between the transmission and jackshaft, and the latter is supported by a spring torque arm.

Final drive is by 1.75-inch extra heavy roller side chains and the adjustable strut rods are fitted with heavy springs which cushion any shock on the jackshaft, protecting that member as well as gears and chains. Provision is made for the fitting of sprockets to drive a loading winch.

The front springs are semi-elliptic, 40 inches, 2.5 inches wide, while the rear members are of the same type, three inches wide, hung outside the frame to reduce height and lower centre of gravity. Two sets of brakes are fitted, the service being on jackshaft, 14 by 2.5 inches, and operated by pedal. The emergency members are 18 by 3.5 inches on rear wheels and operated by hand lever with notched quadrant for locking.

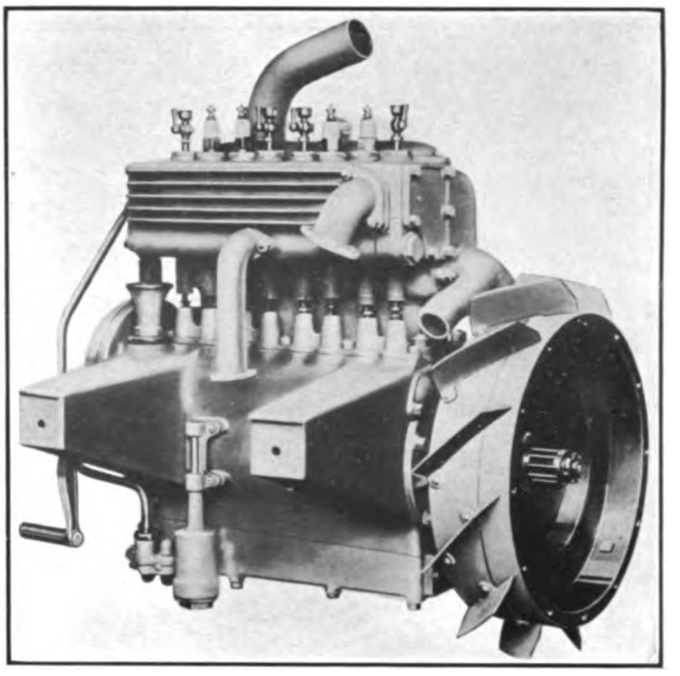
The steering gear is a special Velie design, of the worm and sector type, and operated by a 20-inch wheel. The fuel capacity is 15 gallons and the water tank carries 12 gallons. A differential lock is fitted, this member being operated by pedal convenient to driver. This device permits of the locking the rear axle so that both wheels may be driven positively, thus overcoming the slipping of one.

The front wheels are 36 inches in diameter fitted with single solid tires. An unusual construction is that of the spokes of the rear members, these being three inches square, 40 inches in diameter and shod with five-inch dual tires. For this arrangement the company claims a tire assembly not found on any other truck of equal rated capacity, and that the larger wheels and tires mean long life and a capacity of withstanding overloading without depreciation.

Velie Three-Ton Truck Fitted with Standard Stake Body, the Design of Which Makes for an Even Distribution of Load.

Digitized by Google

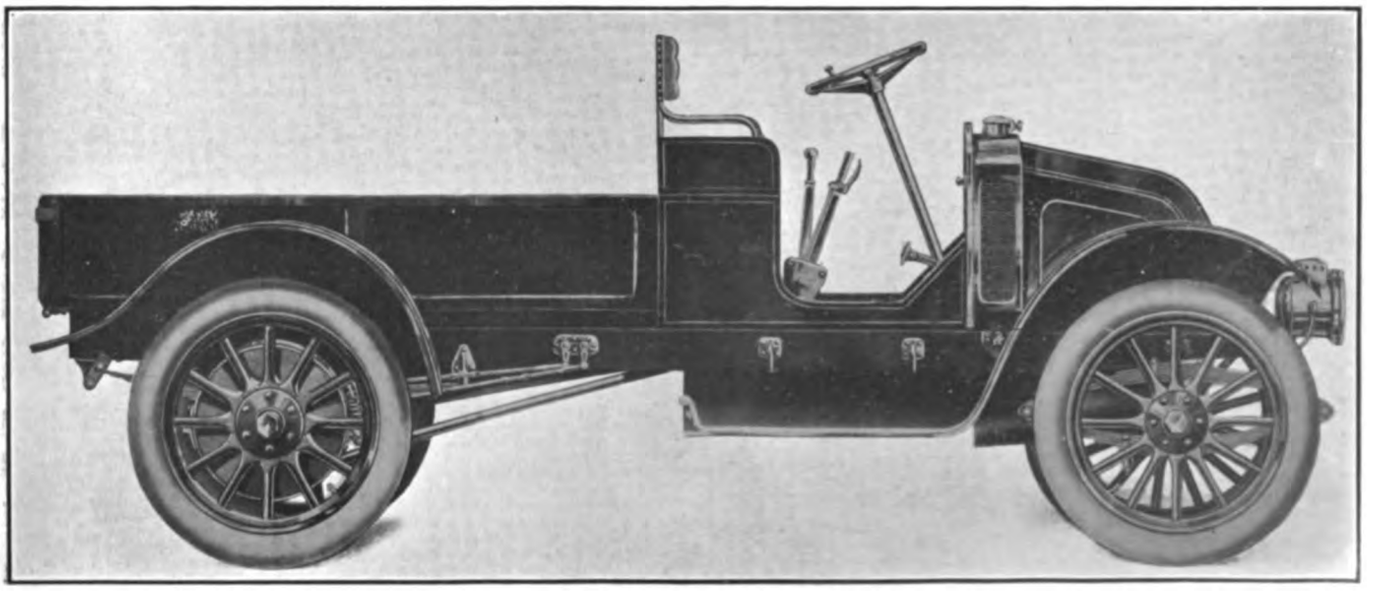
LIPPARD-STEWART OFFERS EXCELLENT FEATURES.



LIPPARD-STEWART delivery cars, manufactured by the Lippard-Stewart Motor Car Company, Buffalo, N. Y., are made in one chassis size, that of 1500 pounds capacity, and to this is fitted many types of bodies to suit the needs of purchasers. The principal styles are seven in number, that illustrated herein being of the open box design which provides a loading space 75 inches long and 45 inches wide.

The chassis embodies many features which are confined to high priced vehicles, and throughout the mechanical details are refined to a high degree. Compactness, simplicity and accessibility are the results of careful designing and construction. Many ideas incorporated in leading foreign commercal vehicles are included, such as fixed spark and location of the radiator. Throughout the best of material and workmanship is in evidence and many units are of unusual strength.

The motor, which is shown in an accompanying illustration, is cast en bloc of special gray iron, and is a four-cylinder, four-cycle, water-cooled unit with a 3.375-inch bore and 4.3125-inch stroke, rated at 20-22 horsepower. The mechanically operated valves are located on the left side and actuated by the camshaft which is supported by large annular bearings. The crankshaft is of special heat treated steel, but 18 inches in length and is of liberal size, 1.875 inches, and has large sized annular ball bearings.

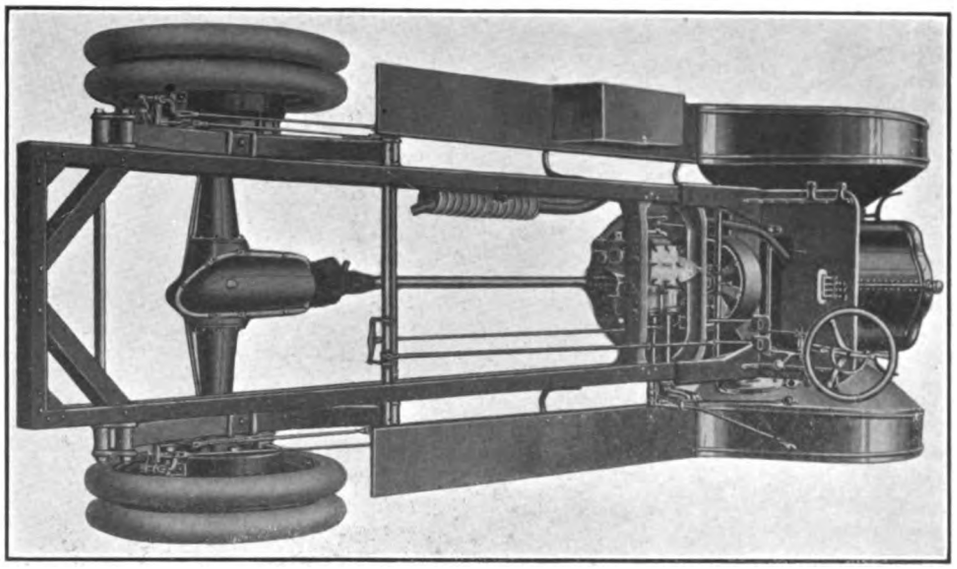


A Kingston automatic carburetor is located on the left hand side of motor, and the arrangement of the intake pipe is such that carburetion is facilitated. The lubrication system is of the constant level splash type, operated by a gear pump which circulates the fluid through the crankcase and tank integral with it, and the capacity is two gallons. Cooling is by the thermo-syphon system, very large water spaces being provided around the cylinder, and the pipes leading from the radiator at the dash are of liberal dimensions, assuring perfect cooling. The usual fan arrangement is dispensed with, a suction member fitted to the periphery of the flywheel serving the purpose. The true high-tension Bosch magneto is employed, this arrangement eliminating the auxiliary ignition system and providing a fixed spark, a practise favored abroad.

The clutch is of the multiple disc type, 12 steel plates against Raybestos being enclosed in a case which is integral with that of the transmission. The latter is of the selective type, providing three speeds forward and a reverse, and the centre control levers are a part of the transmission, eliminating extra parts. The front axle is of the I beam section, with spring seats forged in one piece. The rear axle is a special Timken of the full floating type. Timken roller bearings are used throughout, these being installed in the steering knuckles. The differential is easily accessible by means of a large inspection plate.

The Lippard-Stewart Power Plant, a Compact Design Making for Simplicity—Note the Arrangement of the Fan Blades on the Flywheel.

Liberal brakes of the contracting and expanding type are fitted to the rear wheels, and are 17 inches in diameter by 2.5 inches wide. These are positive in action and easily adjusted. Full elliptic springs are employed in front, long semi-elliptic members at the rear, and an auxiliary coil spring is brought into service when the car is loaded. The frame is of channel section, pressed steel, tapered in front to give a short turning radius, and wide at points subject to stresses. The driver's position is at the left with control member at his right. Pneumatic tires, 34 by four inches, with quick detachable rims are fitted, although a 4.5-inch shoe is employed on some models. The wheelbase is 115 inches and chassis weight, 2200 pounds.



Lippard-Stewart 1500-Pound Capacity Vehicle, the Chassis of Which Contains Mechanical Features Usually Limited to High Priced Cars—Simplicity and Compactness Mark This Design.

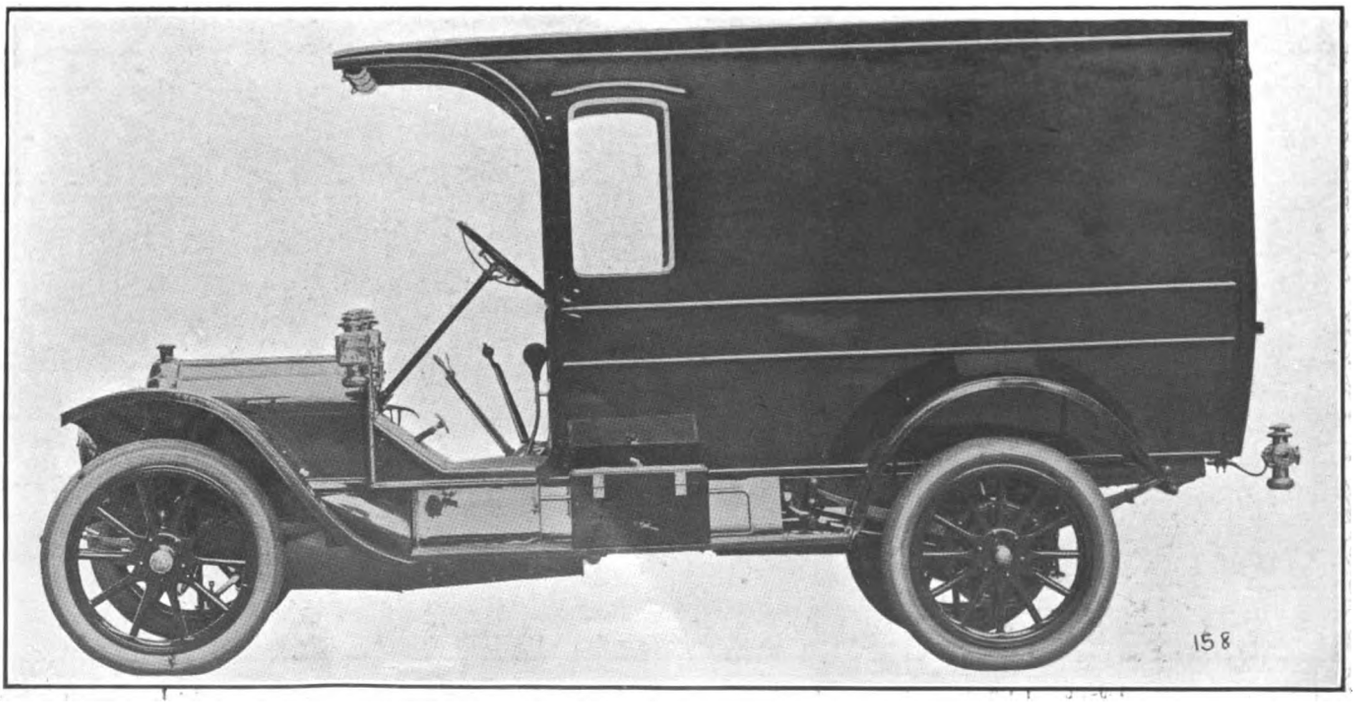
WHITE EMBRACES A VARIETY OF MODELS.

WHITE commercial vehicles, made by the White Company, Cleveland, O., well known maker of pleasure automobiles, are manufactured in sizes ranging from the 1500-pound capacity wagon to the truck designed for carrying heavy loads. The company is a large producer and many of its vehicles are utilized in municipal and government service. Low cost of maintenance, accessibility, and a simple, compact power plant, as well as a high grade of material and workmanship, are the features emphasized.



Chassis of the 1.5-Ton White Truck, Illustrating the Compactness of Power Plant.

Lower fuel consumption is claimed of the motor which is located in front, because of its long stroke and heating of the intake and cooling of the exhaust gases. It is a four-cylinder, four-cycle, water-cooled unit with cylinders cast en bloc and the intake, exhaust and water manifolds cast integrally. The bore is 3.75 inches and stroke 5.125. The mechanically operated and interchangeable valves located on the side of the motor, are of liberal size, and enclosed by a removable plate. The water is circulated by a gear driven centrifugal pump, and cooling is aided by fan-shaped spokes of the flywheel. The radiator is supported in such a manner that road shocks are eliminated. The carburetor is a White design, water jacketed, and ignition is by a high-tension magneto. The lubrication system is reliable and efficient, providing as it does oil to all working parts, and the pump is gear driven with a sight feed incorporated on the dash. A device is fitted for relieving the compression when starting the motor, and is operated by a lever on the dash.

A leather faced cone clutch is utilized, and immediately back of this is suspended the transmission which is of the selective type, providing four speeds forward, with direct drive on the third, and a reverse. All gears are of chrome-nickel steel, ball bearing shafts, and the gearcase is supported on cross members of the frame by a three point suspension.

The chasis of the 1.5-ton truck, which is illustrated here, has a shaft drive from the gearcase to the differential, and is fitted with two universal joints, the rear being telescopic. A large plate permits of easy access to the differential.

Semi-elliptic springs are employed both front and rear, the former being 37 inches long and the rear 45 and of vanadium steel. Two sets of brakes are fitted. The wheels have unusually heavy hubs and spokes, and annular ball bearings are employed. Pneumatic tires are utilized, 36 by four inches, single in front and dual at the rear. The wheelbase is 144 inches and tread 56. The fuel capacity is 18 gallons. The total weight is 3710 pounds. Fitted with the standard express body, the length inside back of seat is nine feet two inches, and 52 inches wide. With the standard stake platform type the length inside back of seat is nine feet six inches by 64 inches wide.

White 1500-Pound Capacity Delivery Wagon, to the Chassis of Which Is Fitted a Number of Bodies to Meet Requirements.

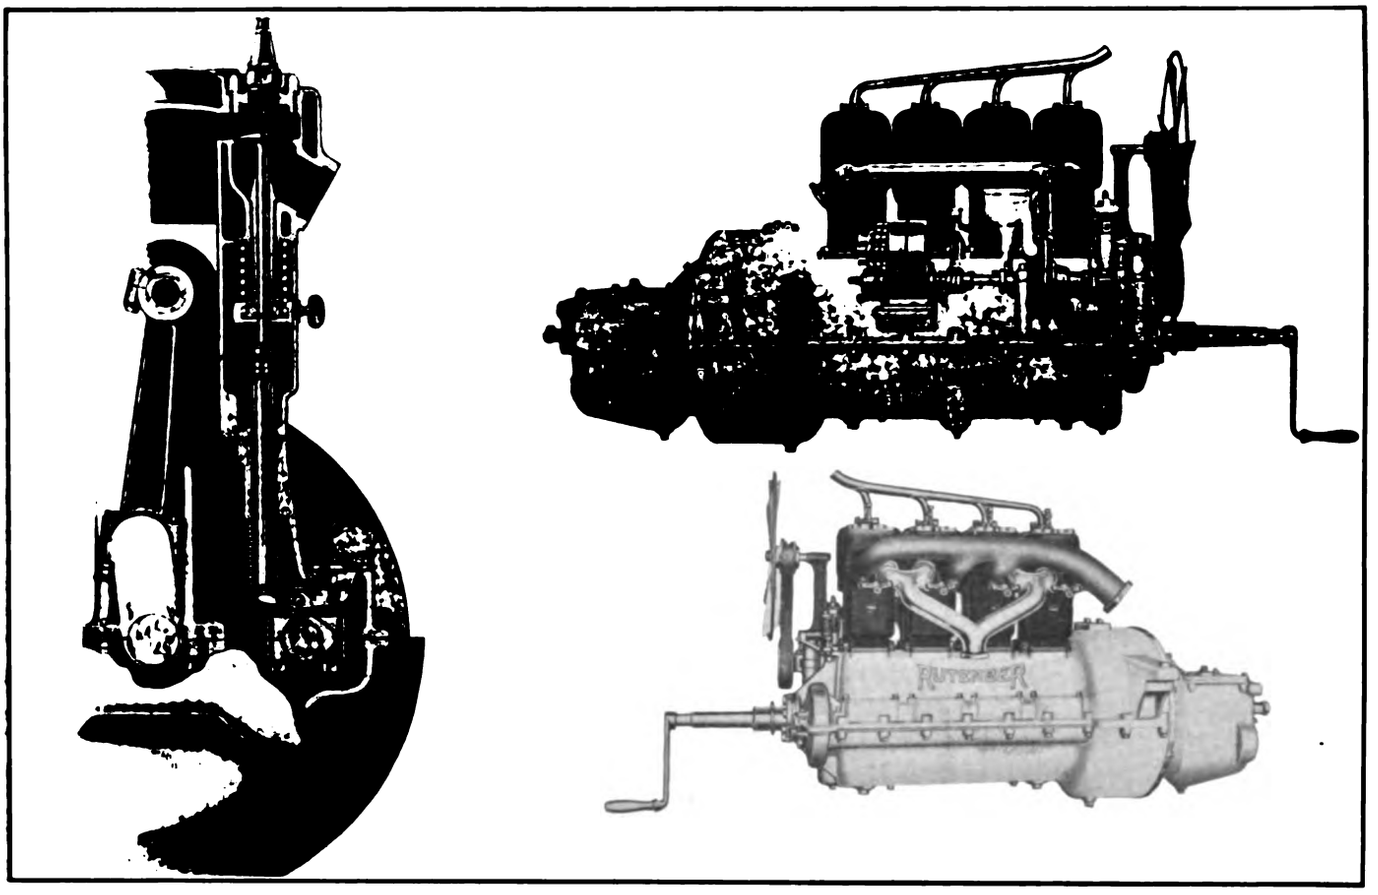
NEW RUTENBER MOTOR DISTINCT IN DESIGN.

DISTINCTIVE features characterize the new type of motor brought out by the Western Motor Company of Marion, Ind., sole manufacturer of the well known Rutenber engine, shown in the accompanying illustration. In designing the unit power plant, which is known as the model X unit, it was necessary to construct a new form of crankcase, one providing for the housing of the flywheel as well as for the attachment of a standard type of transmission. Other features include a new location of the centrifugal water pump and a distinctive design of valve lifting mechanism, the arrangement of which is also depicted.

The motor is similar in every respect to other models produced by this company and is a four-cylinder, four-cycle, water-cooled unit with a 4.125-inch bore and 5.25-inch stroke. The cylinders are of the L head type, cast singly, and of semi-steel. They are machined carefully and ground under heat treatment. The valves are all located on left hand side and are operated through very long guides which are cast separately and pressed into the cylinder.



The valve springs are completely enclosed, and have aluminum caps which can be removed readily for inspection or for the adjustment of the valve lifters. Another important feature, a distinctive design, is the valve lifter arrangement which is illustrated in the cross sectional view. This is made up of a forged arm, swivelled from a plate and fitted with a hardened roller and bushing which is in the centre of this lever and directly over the camshaft. The latter is offset to the right, and lowered to the centre of the crankshaft. This design eliminates noise, provides a quicker opening of the valves, enables the motor to develop more power and allows accurate adjustment. The long steel guide is free from side slap and the entire arrangement is claimed to give a more satisfactorily operating motor as the valves seat properly and do not require frequent grinding. This also is said to eliminate carbon troubles.

The exhaust and intake pipes are located on the same side and are of very liberal size and clean castings. Pipes are counterbored in each opening, as also are the cylinders, and a straight nipple is used in this counterbore. Copper asbestos gaskets are fitted between the cylinders and pipes, and the latter drawn up by tiebars on liberal studs, preventing auxiliary air or gas leaks. The water pipes are tapered brass tubing with cast flanges and are attached to the cylinders by liberal studs and acorn head brass nuts.

The oil pump is located at the front and lowest point of the motor, is entirely enclosed, runs in oil, and is driven by a worm gear from the timer shaft, which also drives pump and magneto shafts. Lubricant is supplied to each of the connecting rod compartments by a tube, and small openings allow it to be delivered to each of the connecting rods and bearings. A constant oil level is maintained and the overflow opening is large, preventing an oversupply in the crankcase and possible smoking.

The centrifugal water pump is located on the right hand side of the motor and is driven from the timer shaft, operplace. The oil sight feed is placed on this side, enabling the operator to note at a glance the amount of lubricant in the reservoir. Oil may be supplied at any time by the lifting ating the magneto which is located in a very accessible of a spring cover. The lubricant is strained through a wire mesh before it enters the reservoir which has a capacity of two gallons. The fan is located on a swivel bracket and a spring device is fitted for the purpose of maintaining tension. It is driven from an auxiliary shaft, and is removed easily.

The motor is suspended by three points, arms being cast integral with the upper crankcase at the flywheel housing to support it at the rear, while the third point is at the front; a drop forged flange which is utilized as a support for the starting crank.

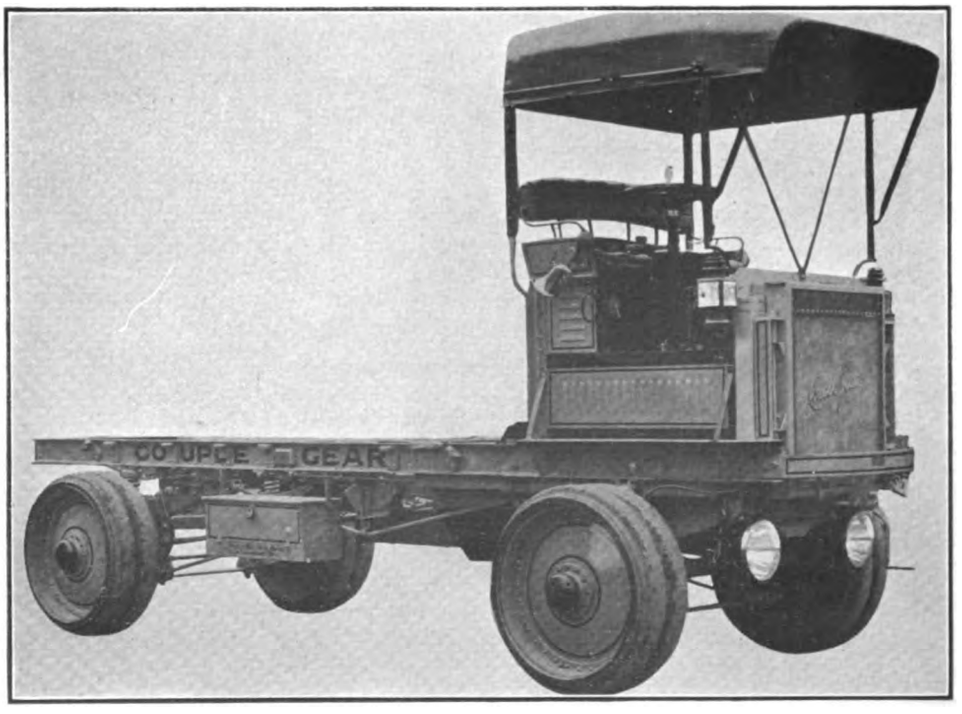
FIVE MODELS CONSTITUTE COUPLE-GEAR LINE.

COUPLE-GEAR trucks, made by the Couple-Gear Freight-Wheel Company, Grand Rapids, Mich., derive their name from the fact that the wheels used contain the driving means, this comprising a gear balanced against a similar member. The vehicles are made in five sizes, the one, 3.5 and five-ton battery driven forms, and the 3.5 and five-ton gasoline-electric types. In the latter, the gas engine drives the generators, which replace the batteries, the wheels being the same, the only change being the method of obtaining the current.

Showing Wheel Disassembled to Illustrate Position of Armature and Method of Fastening Motor in Place, Also Driving and Driven Bevel Gears.

The wheel, which is illustrated herewith disassembled, is of hollow metal and carries the driving electric motor inside. The energy of this is applied to the wheel at two opposite points, with a balanced division of the work accomplished by two driving pinions, one on either side, this being effected by a device called an evener.

These two driving shafts constitute an extension of the motor armature in opposite directions, and carry small bevel pinions, which mesh with very large bevel gears attached to the exterior metal casings of the wheel. One meshes with the inside gear, the other with the outside, the armature shaft being set at a slight angle to allow such action. This gives the same direction of rotation to both parts of the wheel, while the same sized pinions and gears, and like prolongations of the armature result in producing exactly similar speeds.



The attachment of the axle stub on which the wheel turns, is made integral with the motor castings within, so that an elongation of the inside stub, keyed to a taper sleeve in the steering knuckle holds the motor in position. This insures that the member shall be held horizontal while the wheel revolves around it.

This same construction allows of the wheel being turned around the knuckle pivot without interfering with the motor action or the transfer of electric current to the motor. It is the same for all wheels, this arrangement providing greater traction.

In the 3.5 and five-ton models of the battery driven type, the batteries are underslung in the middle of the chassis. These are of 44 cells each, the five-ton having 19 W. B. plates against 17 in the smaller car. The controller is of the cylinder type, giving five speeds forward and a like number of reverse. By aid of the patented motor drive, with its 25-to-one reduction, the maker claims a 97 per cent. efficiency. Steering is by means of a vertical post, using a worm and sector gear. Two sets of brakes are fitted, both operating within the wheels.

In the gasoline-electric cars the motor replaces the battery as a source of current. A four-cylinder engine is employed and this with the generator is mounted on a sub-frame. A special generator is utilized and is rated at 12.5 kilowatts at 100 volts, 680 revolutions a minute, and will run without sparking at an ampere load of 200 per cent. in excess of its normal rating. It is of the six-pole type with an equal number of commutating poles, compound wound with dropping characteristics, which automatically assists the engine to hold or increase speed with the rate demanded. The rheostat is connected to the fields and carried on the dash in such a manner that the driver may raise or lower the gear ratio at will. On the 3.5-ton size the wheelbase is 144 inches and tread 66, the tires being 36 by 3.5 dual on all wheels. An electric brake is fitted in addition to two sets of mechanical members.

On the five-ton vehicles illustrated herein, the four motors employed are rated at three horsepower each, giving a total of 12, but all are said to be equal to an overload of 200 per cent. which with the four-wheel traction is said to be equal to the ordinary 50-60 horsepower engine when drive is effected by two wheels only.

Couple-Gear Chassis, Designed to Carry Round Oil Tank 14 Feet Long.

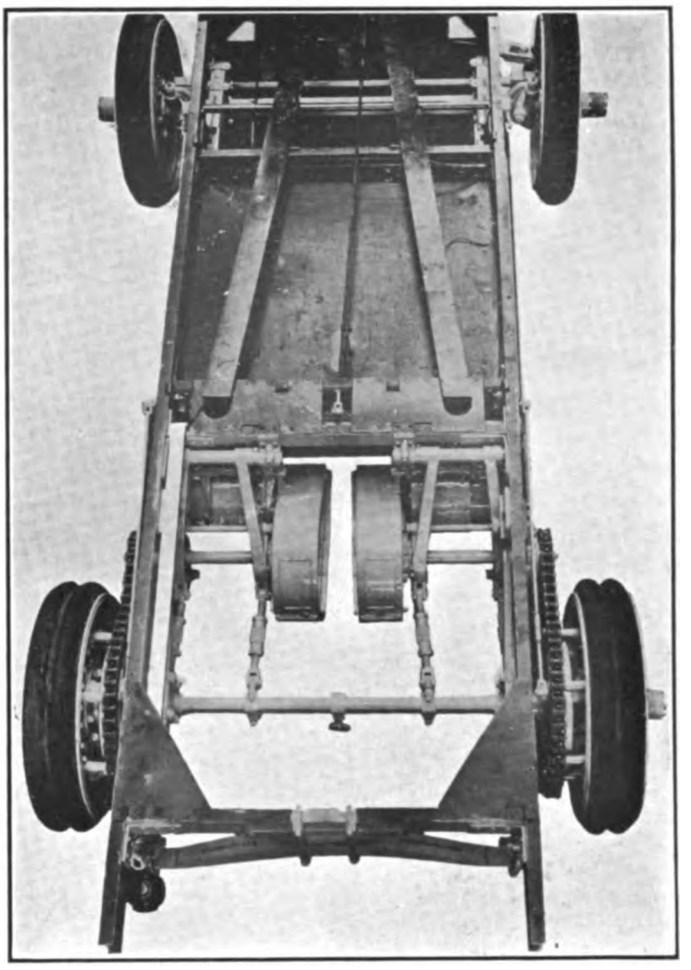
WAVERLY ELECTRIC VEHICLES WELL DESIGNED.

ELECTRIC commercial vehicles manufactured by the Waverley Company, Indianapolis, Ind., are made in carrying capacities ranging from 600 pounds to three tons. The chassis of the latter size is illustrated here, also a fleet of mail wagons of 2000 pounds capacity, adopted by the United States government. The larger vehicle is fitted with Waverley motors built by the company so that consistent performance can reasonably be expected. The battery equipment is 42 cells, 19 M. V., Hycap, and the mileage on hard, level roads, loaded one-half the distance, is set at 35 miles. The rated speed is nine miles an hour.

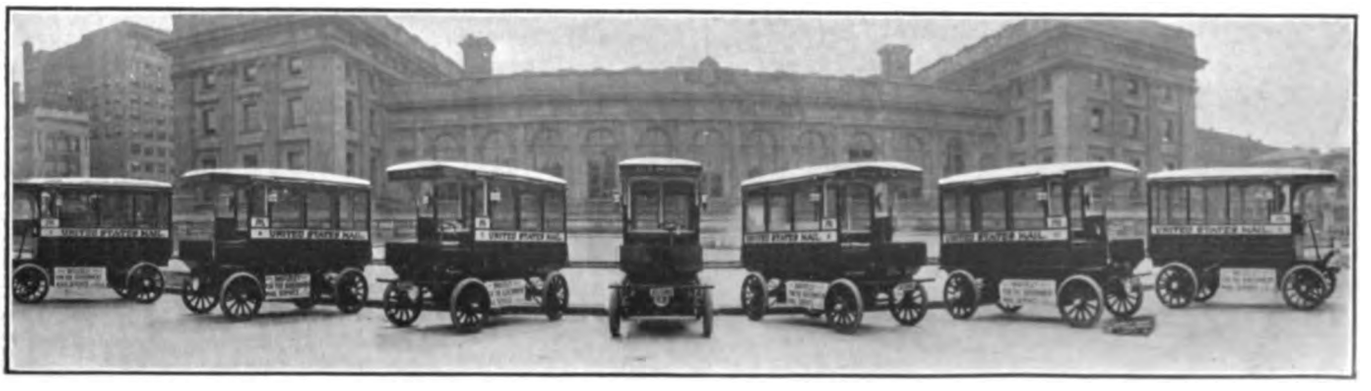
A double motor equipment is fitted, this being two series-wound, 80-volt members supported to the sides of the frame in heavy cast steel brackets. These also carry the jackshaft bearings and brakes. Drive from each motor to the countershaft is through a Renold silent chain, and final drive by roller side chains. The primary drive chains are enclosed in metal cases fitted with hand plates that may be removed easily for inspection or other purposes. Radius rods extend from the jackshaft to the rear axle and these are provided with turnbuckles making adjustment a simple matter. Similar members are fitted between the outer ends of the jackshaft and rear axle and this arrangement provides a double alignment under all loads. The motor and jackshaft rotate on annular ball bearings.

The frame is constructed of five-inch channel steel and the members are hot riveted throughout, with heavy gusset plates employed at the ends. The axles are of drop forged alloy steel, the wheel pivots being ground carefully and fitted with Timken roller bearings. The front springs are semi-elliptic, and are anchored at either end to cast steel brackets on the frame and held securely to the axle by steel clips.



The platform type is utilized at the rear and all springs employed are of a special steel, the members being built up of a number of thin graded leaves. The rear sets are held forward in frame side brackets clip centred to the rear axle and bearing in free action hangers to the ends of the transverse member. The springs are long, providing easy riding qualities.

Two sets of brakes are fitted, one on the rear wheels and the other on the jackshaft, both being operated by pedal. The wheels are of wood, artillery type, 36 inches in diameter, and the front members are equipped with solid five-inch single shoes while the rear have 3.5-inch dual. A sector and pinion form of steering is utilized, positive in action and having few workng parts.



The Waverley controller is of the continuous torque knife blade type, and there is no interruption or break in the current in advancing from one speed to another. It is located under the driver's seat, and operated through a vertical rubber handled lever, which may be locked securely. Four speeds forward and a like number of reverse are obtainable by this type of controller.

The wheelbase is 118 inches and gauge 73 inches. With standard body the width of the clear loading space is four feet six inches, and length back of driver's seat, 13 feet.

The Waverley Company builds a number of commercial vehicles ranging from 600 pounds carrying capacity to the three-ton vehicle described, and a variety of bodies are fitted to meet the requirements of various lines of industry. Quite a number of the 2000 pounds capacity trucks and other sizes have been adopted by the postal authorities and have given excellent service under all conditions. In addition to the business cars the company constructs pleasure vehicles. The Waverley motor is installed in all models.

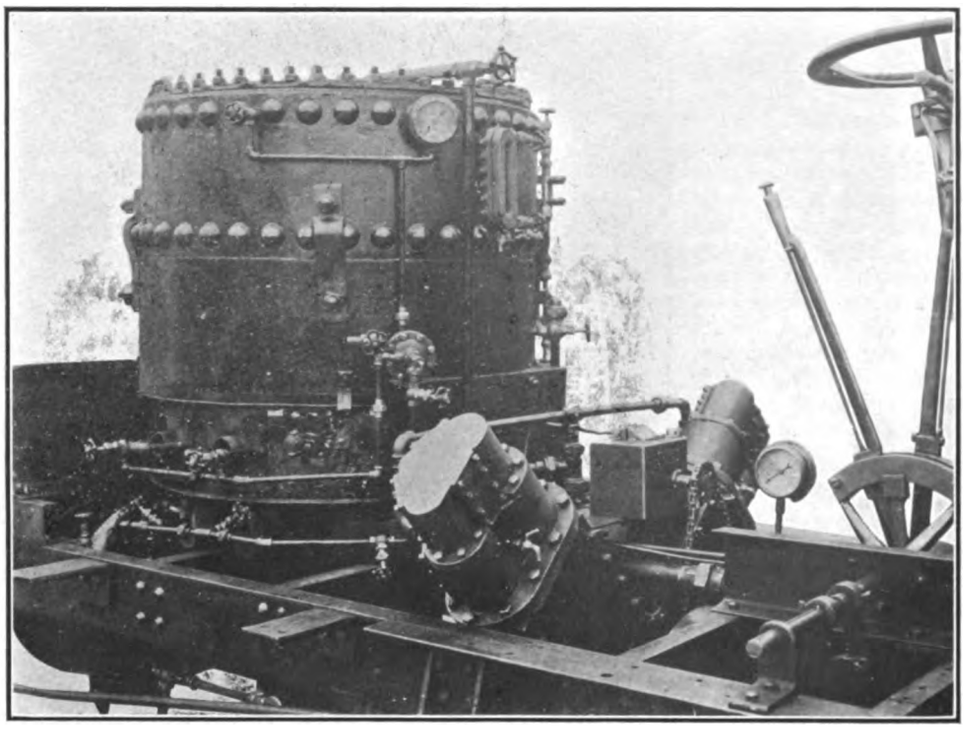
PRESENTS STEAM TRUCK FOR HEAVY WORK.

THE AMERICAN steam truck is produced by the American Steam Truck Company, Lansing, Mich., in the five-ton size, for which is claimed an economy of operation and maintenance not possible with other types of vehicles. This concern and its product are decidedly new in the commercial car field, and a description of the machine will prove of especial interest.

The engine used is designed to develop 50 actual steam horsepower at 300 pounds pressure and 400 revolutions. It is of the twin, quadruple, compound, reciprocating type, assembled in the form of two complete engines in one casing at an angle of 90 degrees, the crankshaft containing a single pin at the apex of the triangle. It may be described as an eight-cylinder machine, four cylinders on either side, each group acting in unison.

The steam enters all four cylinders on either side in such proportions as to exert the same pressure on each of the four pistons, of course at varying steam pressures and at varying dimensions of the cylinders. Regulation is by means of a hollow piston valve, acting in conjunction with properly proportioned ports, in such manner as to prevent expansion in either ports or valves. Steam is cut off at seven-eighths of the stroke, the table selected being as follows:



Cylinder	Diameter	Stroke	Area, inches	Pressure, pounds
High pressure	2.5	5	4.90	300
First intermediate	3.5	5	4.37	200
Second intermediate	5.0	5	19.63	133
Low pressure	7.0	5	38.48	89

The engine takes steam through a .5-inch pipe at each end, exhausting in a tube 1.25 inches in diameter. While it is capable of 1000 revolutions a minute, it has a normal speed of from 300 to 600, at a car speed of five to 10 miles an hour. The reversing gear is so arranged as to permit instant reversal of the engine under a full head of steam, this being in itself a positive form of brake.

The generator is known as the semi-flash, drop tube, water level boiler. It consists of two parts, the boiler and the drop tubes, with a shell 24 inches high by 32 inches in diameter. Inside of this shell is the body of the boiler and the furnace. The former is divided into a steam dome above and water reservoir below by the water level line, which is held constant. There are 40 1.5-inch drawn steel fire flues passing through it. The top and bottom plates, or heads, are .6875-inch flanged steel, securely riveted. Two hundred and forty patented seamless circulation tubes are inserted in the bottom plate and extend 10 inches down into the furnace. A water leg completely encircles the boiler, having two brass plugs for cleaning the shell at its bottom. The generator is covered with a steel jacket lined with asbestos for economizing heat. Engine and generator are close together insuring slight condensation in transmission of steam.

By the condensing system employed the steam that would otherwise be exhausted and wasted in the open air is changed to water, which is returned to the boiler in a heated condition and used over and over again, improving the appearance of the truck in operation and economizing on water and fuel.

After entering the engine at about 300 pounds pressure and 450 degrees temperature, the steam is expanded four times in the four cylinders and is then exhausted at low pressure and temperature into a .125-inch pipe, which in turn connects with a 1.5-inch pipe leading to a separator where the oil is extracted from the steam and the pressure of the latter reduced. It then passes from the separator through a .5-inch tube to a feed water heater, where two things are accomplished; the water about to go to the boiler after it has passed the pump, is heated almost to boiling point, and the heat necessary to do this is extracted from the exhaust steam, again reducing pressure and temperature.

Power Plant of American Steam Truck, Including Generator, Engine and Burner.

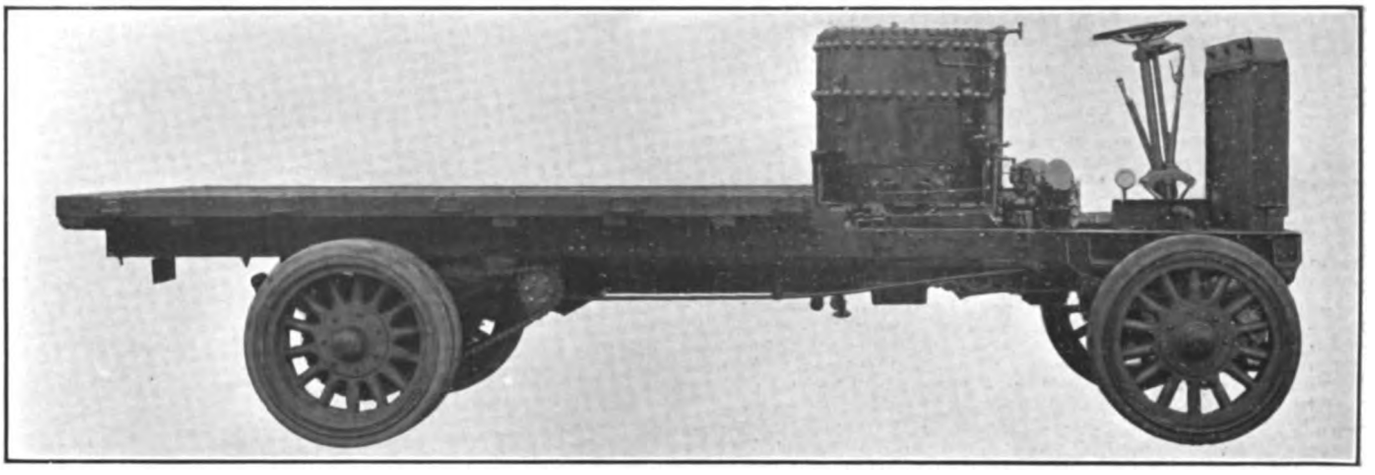
From the feed water heater, the exhaust passes in pipes through the twin tank and into the bottom of the condenser at the front of the chassis, which it reaches partially condensed. It has travelled nearly 25 feet, is practically devoid of pressure and has a very low temperature. Here, the work of turning the steam into water and also of cooling it is finished before it returns to the water tanks. The condenser has an aluminum top and base connected by thin copper tubes.

In operation, the steam is condensed in the rear half, while the water is cooled in the front portion, by the action of the air which is forced through the tubes by a large fan located directly behind it. To prevent any possible back pressure on the engine, two open pipes lead any unusual accumulation of air or steam to the stack.

The burner used is of the standard type, having two fuel feeds. The fuel is vaporized before entering the combustion chamber and as kerosene is employed it produces a very hot, blue flame, which acting upon the drop tubes of the boiler, generates steam quicker perhaps than any other liquid fuel.

The main flame is shut off at 300 pounds boiler pressure, by an automatic regulator which can be set for any desired pressure, and it is claimed that as the plant generates an over abundance of steam, the burner is not in operation more than two-thirds of the time when the truck is running. It is further claimed that the fuel consumed in furnishing steam for the vehicle will not exceed 15 gallons of kerosene for a day's haul of 10 hours.

Pilot lights burn constantly underneath. With these



Digitized by Google

once fired the burner is always instantly ready to respond and keep the steam up to working pressure. This also may be maintained in cold weather, when the truck is left standing for long periods, by the pilot lights alone.

Owing to the fact that there is constantly 20 gallons of water in the boiler, "firing up" with all parts cold is a longer operation than by the full flash type, but it is claimed that after lighting the pilot lights, the operator will have a working pressure of steam in 20 minutes. When the burner is properly operated it is said to be smokeless.

An automatic regulator is placed on the sides of the generator, which constantly maintains the water at a stated level, as follows: The two pumps furnish water faster and in larger quantities than is necessary to supply the boiler, and force this all of the time the engine is in operation. When the fluid is below its proper level, they pump directly into the boiler through this regulator. When this level is reached the action of the water in the boiler (which is never hotter than 212, no matter how hot the steam may be) closes a valve in the regulator and the course of the water is changed, by passing back into the tanks, but to make assurance doubly sure, a high pressure glass keeps the operator informed as to the exact state of the water line.

Notwithstanding that the water, fuel and steam are all controlled automatically, arrangement is made for the hand control of these elements from the driver's seat. The water glass is stationed immediately behind the seat and

Chassis of American Steam Five-Ton Truck, Showing Complete Assembly of Parts and Their Relation to Each Other.

all gauges on the front of the dashboard. The steering wheel is located on the left hand, and the throttle attachment on the steering post consists of a short lever at the left. Opposite this and fitted to the same collar is a similar lever for reversing the engine. Two long levers operate, respectively, the disengaging clutch and the brake. No transmission is used.

The power plant, engine, generator, burner, etc., are enclosed within the cab. A chain driven air pump, maintaining automatically 60 pounds pressure in the 30-gallon tank, located under the bed and over the rear axles, is used to transfer the fuel from tank to burner. The water supply, 60 gallons for one full day's haul, is contained in two tanks of 30 gallons capacity, each located amidships.

The chassis is constructed of six-inch channel iron bed. All jackshaft and axle bearings are of the Timken roller design. Swinehart tires, 4.5-inch dual rear and five-inch front, are fitted. Any desired form of body can be furnished according to the wishes of the purchaser.

QUIXTART STARTS COLD MOTORS.

A new compound called Quixtart has been placed upon the market recently, and is used as an aid in starting gasoline engines when the cylinders are cold or when the spark is weak. It is said that by its use much time may be saved in cranking as a small quantity of the material poured into the carburetor, auxiliary air valve or intake system at once gives a normal mixture, even in the coldest weather, facilitating the starting of the engine It was first produced by a well known chemist for his own use, but it proved so successful that it was placed upon the market. It is produced by the Quixtart Chemical Company, Providence, R. I.

NEW YORK'S TAXICAB REGULATION.

Alderman Courtlandt Nicoll of New York City has announced his intention of introducing a new ordinance, soon after the organization of the recently elected board in January, reducing the present taxicab rate of 80 cents for the first mile, to 50. Concerning this matter his draft reads as follows: "For the first half-mile or any part thereof 30 cents; for each additional one-third of a mile, 10 cents." The ordinance fixes waiting charges at $1.50 for the first hour or any part thereof exceeding five minutes, and 50 cents for each additional half-hour. For a stop not exceeding five minutes there will be no charge.

Just how this proposition will be received by the taxicab companies is problematical, inasmuch as they claim to be operating on a close margin under the present charges. Still another phase of the situation is offered by the proposed ordinance, in that hotels, railroads, clubs and restaurants will be compelled to accept the service of vehicles, even though such cabs are not owned and operated by the company to which the service privilege has been sold.

Under the present plan the transportation companies pay more than $300,000 annually for these privileges, as evidenced by the following table, prepared by the comsioner of accounts:

Mason-Seaman Transportation Company	$110,513.04
Car & Taxi Cab Company of New York	99,516.43
Connecticut Cab Company	52,187.96
New York Transportation Company	20,232.02
Universal Taximeter Cab Company	20,075.00
Renault Taxi Service	11,496.10
James T. Haverty's Stable	11,252.50
Kayton Taxicab & Garage Company	7,592.72
U. S. Motor Cab Company	6,500.00
Patrick W. Hanrahan	4,800.00
Long Acre Motor Company	2,877.88
Carnegie Hill Livery & Motor Company	1,965.12
New Taxicab & Auto Company	1,606.44
Thomas Comba (approximately)	1,500.00
Joseph H. Penders	1,200.00
Frawley Transportation Company	1,200.00
Cruice, Keelan & Co.	1,100.00
Hart Bros. (approximately)	600.00
B. Van Cott	600.00
Natius Taxicab Company	300.00
Franklin & Ryan	125.00

Not all of these concerns operate motors, and the ordinance is not aimed at such vehicles alone, inasmuch as it reduces the charges for horse drawn cabs as well. It is probable that both classes of service will unite in an effort to prevent its passage.

Information given on request. All advertising copy must reach this office not later than the 25th of the month preceding.

Anonymous communications not considered. Correspondence on subjects relating to trucks, delivery wagons, taxicabs, tractors, all motor driven farm, fire, and municipal apparatus, the motor industry and the trade, will receive attention. Stamps must be enclosed to insure return of unsolicited contributions.

Entered as second class matter, February 25, 1911, at the Postoffice at Pawtucket, R. I., under the Act of March 3rd, 1879.

CONCERNING THE COMING SHOWS.

Business men who are contemplating the installation of power wagon equipment, will find much of value in a visit to one or more of the so-called national shows. At these it will be possible to study the merits of the productions side by side, with every opportunity to consider the advantages of each with reference to its application in the particular work to which it is proposed to apply it.

While the motor truck may be regarded as having passed the experimental stage, its thorough practicability and dependability having been demonstrated under all sorts of conditions and in every application of service, it undoubtedly is true that the forthcoming displays will bring out a number of refinements in design and details of construction which may be considered as new. It is reasonable to expect that the commercial vehicle will pass through the various stages of development in much the same manner as did the so-called pleasure car, but with this exception, that the industry has been able to learn much from its experience in the older field.

It is somewhat difficult to forecast the features which will be considered important, inasmuch as each business man will be guided largely by his own needs in arriving at a decision on this point. It is perhaps safe to suggest that the effort of the manufacturer will be largely toward economy and reliability, for it must be admitted that he shares with the purchaser in the desire to bring about such results. Every truck sold which presents a satisfactory record in this respect means that it will be that much easier to place others and it is sufficiently well understood that the possibilities for sales are as yet quite unlimited.

TREND OF SELLING METHODS.

Those engaged in the business of selling commercial motor vehicles appreciate thoroughly that absolutely nothing is to be gained by an attempt to discredit the product of other makers. There was a time when this fault was rather too prominent, but it was soon recognized that the good of the industry demanded it be eliminated forthwith. At present, the trend is notably along lines entirely opposite.

The action of at least one motor truck manufacturer in establishing a campaign of education, in which the object is that of interesting merchants and other business men in the advantages to be obtained by the adoption of the mechanical transport, without special reference to any particular make, is a decided innovation. There can be little doubt, however, that the ultimate result will be most satisfactory to the concern which inaugurated the experiment.

Few will be disposed to criticise the statement that the industry needs some such means of calling the attention of the general public to the specific opportunities afforded by its product. That conditions have reached a point where it seems advisable for the manufacturer to devote a share of his investment to this purpose is sufficient indication that the business of producing commercial vehicles is on a stable foundation.

NEED FOR SPECIAL BODIES.

Body design is a matter which is receiving deserved attention on the part of those interested in the future of the industry. There can be little question that the body equipment is quite as important as the chassis, and there is every reason to believe that a field is opened up in its consideration, which offers a splendid opportunity for certain lines closely allied with the horse drawn vehicle, destined to be superseded in a large measure by the motor transport.

Special bodies, in this instance, should be taken to mean those carriers which are to be used in special service. It hardly can be denied that the coal business, for instance, requires a different construction than would apply in the hauling of lumber. Each particular line must be studied with a view of bringing about designs that will apply especially thereto, having in mind the economical operation of the truck. And this will be found to cover a much wider range than is apparent at first thought.

Whether or not the manufacturer shall attempt to solve the problem himself, or call upon the already organized body builder for aid in the matter, must be decided by each in turn. It may be suggested, however, that if the latter course be chosen, the two can work in conjunction without conflict. In fact, it is quite possible that the body builder may be able to offer valuable assistance, because of his long association with this particular branch of his industry.

THE A B C OF MOTOR TRUCK OPERATION.

A Simple Exposition of the Principles Underlying Operation, Maintenance and Repair of All Motor Driven Commercial Cars, Outlining Details of Components. Part XIV—Necessity for Clutches and Their Forms.

By Morris A. Hall, M. E.

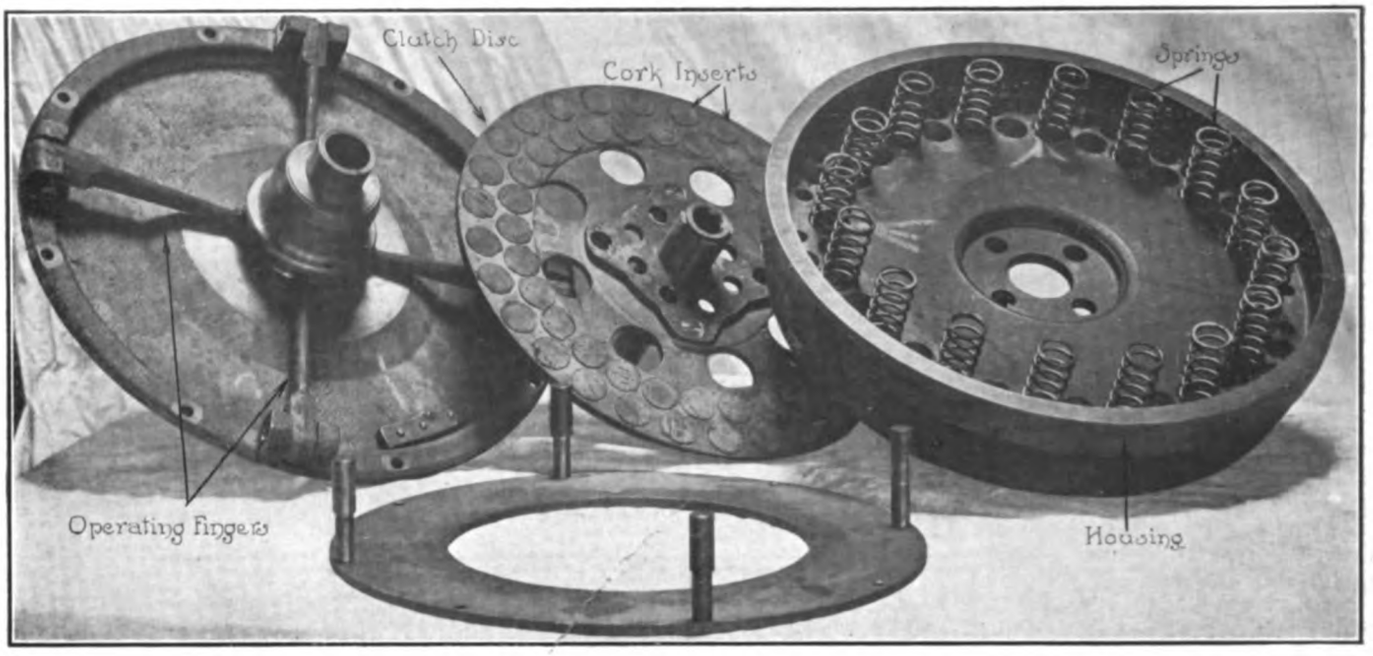
HAVING considered the parts entering into the construction and operation of a motor truck engine, including its form, cycle of operation, means for a supply of fuel, a source of ignition for this, and proper and efficient lubrication, there remains the use of the power developed, its transmission to the road wheels so as to propel the vehicle, and means for controlling its application. An important member in this group is the clutch, interposed between the motor and the change speed mechanism. The operation of this member will be explained in detail, presenting a number of actual examples.

A gasoline or other type of internal combustion engine has a limited output of power for its size and form, this varying widely from one unit to another but each possessing a well defined maximum, beyond which it is impossible to go. If a load be placed upon it in excess of that, the engine will stop and refuse to work longer under those conditions. This necessitates a form of connection between motor and driving group which will permit of some slippage, sufficient to avoid stopping or as it is called commonly, stalling the engine. If this could be designed and constructed so as to hold right up to the ultimate maximum of the power unit, and slip as soon as that were exceeded by the slightest amount, it would be ideal; but such is not the case, as will be shown later.

The hydrocarbon power generator must start slowly, at which time the output is very small. As the speed increases, the power developed is augmented in a proportionate ratio. That is to say, the work which such a motor can do varies with its rotative speed, this being large between certain limits, small when the upper end is passed and very slight at the lower point. The interval between the two is called the critical range.

To be exact, this differs for each and every engine produced, but a general statement may be made as follows: Lower limit, 800-900 revolutions a minute; upper extreme, 1500. Below 800 turns, the power developed will be exceedingly small, and bear a very low ratio to the possibilities above that point, and what is of much greater importance, to what is needed for the propulsion of the car. Let it be assumed that at 550 revolutions the output would be but half of that at 800, the latter in turn, being but 66 per cent. of the maximum.

If the total be needed to start the car from rest, which is reasonable, for in all cases of operating vehicles whether they be railroad trains, trolley cars, or motor trucks, the movement from rest takes many times as much energy as it does to keep it in motion after it has been started, then the highest speed also will be required. This necessitates a form of connection between engine and wheels which will permit of the former being started and run alone, until the maximum speed of rotation be reached, and consequently the greatest power developed, when it must allow of connecting or joining the two gradually yet at the conclusion of engagement, decisively.



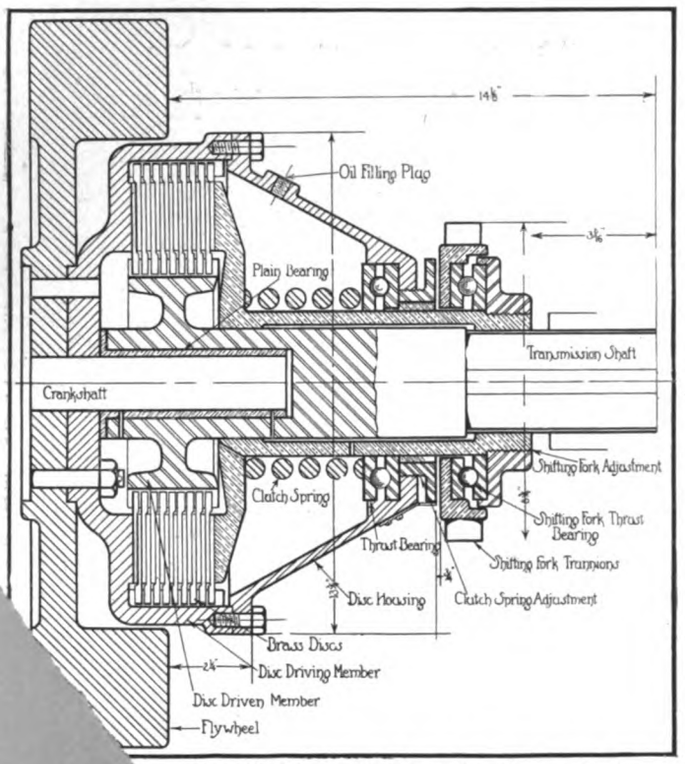


Fig. 53—Cork Inserts Form One-Plate Clutch Used in All Knox Heavy Motor Trucks—Note Numerous Springs in Position Within Flywheel.

After slowing down the car, too, the starting up again must be considered always, since if the motor speed be reduced to a very low figure, while the vehicle is brought to an actual stop or very close to it, the situation is the same as in the first place, and the engine must be disconnected, speeded up to a high power output point, then connected with the driving means. When the large number of starts and stops made during the course of a commercial vehicle's day is considered, the importance of this easy and rapid connection and disengagement becomes apparent. From this point of view the clutch is a large factor in successful and efficient operation.

The clutch fits into the niche created by these three fundamental needs of the motor car, namely First, a slipping member to avoid overloading and consequent sud-

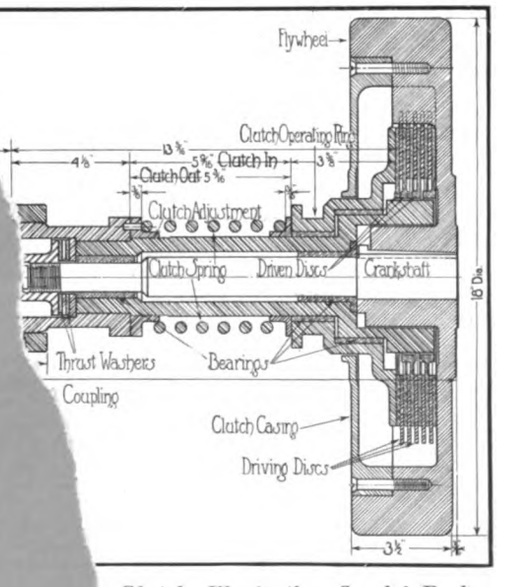
... one



three principal units, motor, clutch and transmission, as individual parts, and in the majority of cases, placed some distance apart. On those of the chain driven type, the gearbox is located at the driving countershaft and many times, as a unit with it. Between the two the clutch position varies with the designer from very close to the power unit or incorporated in its case, back to inclusion with the transmission case, and all of the intermediate locations.

This being true, it can be discussed separately. There are three classes into which all clutches may be divided: Disc, cone, or band. The first is divisible into single plate, so-called, with three friction surfaces, and multiple disc with upward of 10 plates. The second form may fall in one of two divisions, the plain or the inverted cone. The last also is made in two ways, the contracting band and the expanding.

The first class is well represented in the accompanying cuts, Fig. 53 showing a one-plate form, Fig. 54 another with 18 discs, Fig. 55 a form with 11 plates and Fig. 56 one with 15. While the power transmitted in the case of the first, second and last is approximately the same, the difference in the plates lies largely in size and the pressure of the clutch spring. The single disc is of a very large size, within a portion of an inch of the flywheel diameter, while the springs though small are numerous and stiff, yielding a large total pressure. This form also has cork inserts, which supply the larger part of the friction surface, thereby increasing its ability to transmit power. This is the clutch used by the Knox Automobile Company, Springfield, Mass., in its trucks and commercial cars.

Fig. 54 is a design of the writer's for a high powered gasoline railway car to carry 35 passengers. The plates were of a very ordinary grade of brass, cast with the proper lugs and machined only on the contacting faces. The entire job was a very low priced one, but the surface afforded a large margin over any possible requirements. By comparing the size of the flywheel here with that of Fig. 53, some idea of the relative dimensions of the two kinds of discs may be gained, although this last is a slightly larger balance weight, say 21 inches as compared with 18. The extra strong spring will be noted and the generous provisions in bearings and elsewhere for hard work and considerable abuse. Attention is called to the two points of external adjustment of the clutch spring and outside take-up possibilities for the shifting fork thrust bearing.

Another of the writer's railway car designs, but for a lighter vehicle of much less power is that of Fig. 55. Here is seen a more compact arrangement, although the general design of the discs is very similar. The five driving discs carry three slots each around the periphery, which fit over similar notches machined within the flywheel. The six

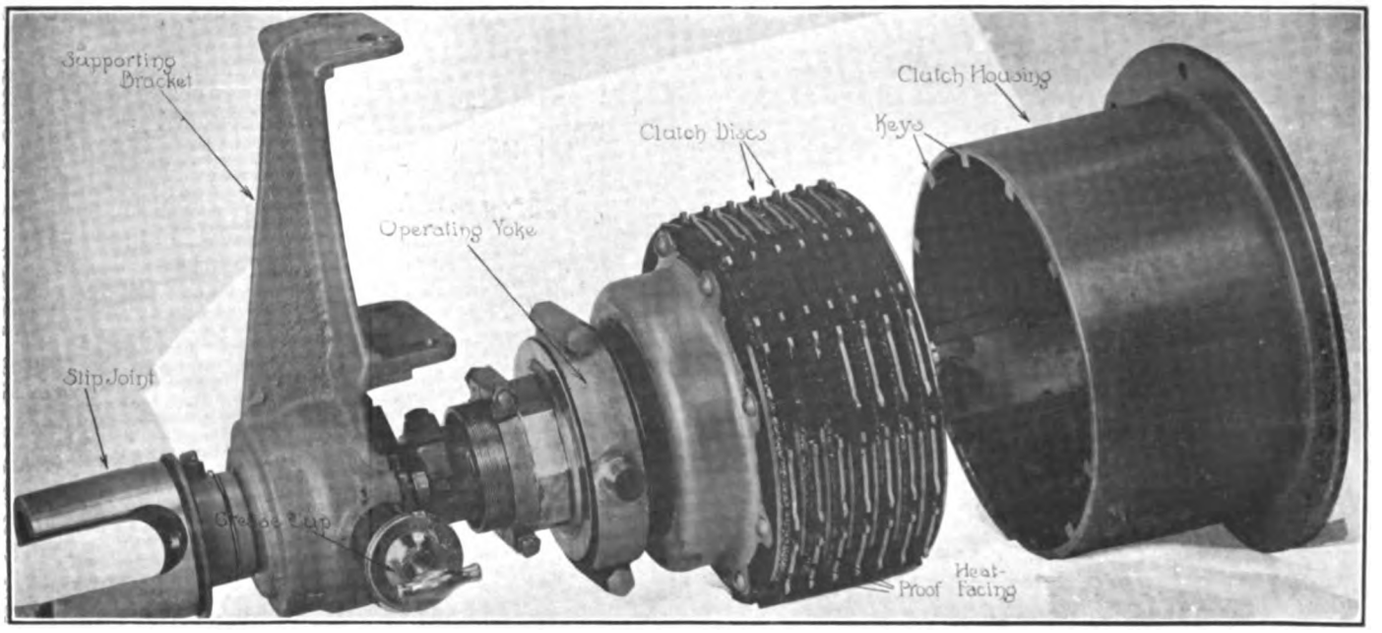

Fig. 56—Type of Multiple Disc Clutch in Which a Large Number of Plates Is Used—Those Shown Are Faced with Heat Proof Material.

driven members each have a hub twice the thickness of the plate, in which is a set of three notches to accommodate an equal number of keys on the driven shaft. The universal coupling at the left was provided for the purpose of quick and easy demounting. By removing a pair of bolts holding the two casing pieces together, these could be lifted off the squared ends of the shafts over which they fit, leaving a clear space eight inches long in which to slip off any of the parts. The spring is of a round section wire of fair size and considerable stiffness.

A series of 15 stamped steel sheets, seven with external notches and eight with internal, form the principal parts of the clutch depicted in Fig. 56. These have a facing of asbestos fabric, similar to that used for brake linings. Other features of this design will be seen in the figure, which is well worth extended study.

Passing to the cone clutch: This may be considered as a disc which has been rolled up, cornucopia shape and the ends cut off. Treated in this manner, it becomes similar to the disc in every respect. The actions of engagement and declutching become a matter of allowing the spring to push the two coned surfaces together or pressing them apart by means of a pedal. In Fig. 57 is seen one of the reversed type, while Fig. 58 is another but double surfaced in order to transmit a larger amount of power. Fig. 59 depicts a plain cone so that a means of comparison is afforded.

The reversed form calls for more parts and has an enclosed spring, permitting of efficient lubrication. The design shown in Fig. 59 of the plain form also happens to show an enclosed spring, but generally this type gives an external position for that important member. Fig. 57 is used in one of the best three and five-ton trucks on the market, while Fig. 58 was designed by the writer also, for a 30-passenger railroad car with a peculiar double transmission. The form in Fig. 59 is used on the Sampson five-ton vehicles made by the Alden Sampson Manufacturing Company, Detroit. Fig. 60 shows a detail of the clutch spring used in the Sampson truck, giving an excellent idea of its proportions, while the preceding figure depicts it in position. The spring in the Mack design at Fig. 57 measured 3.25 inches inside diameter, using .375-inch square wire. It was 5.75 inches long free, and required 225 pounds pressure to bring it down to the four inches it occupied in position. This amount then, was the pressure exerted normally to hold the clutch in engagement.

Aside from the Kelly truck, manufactured by the Kelly Motor Truck Company, Springfield, O., few band clutches are used in commercial cars. This one is of the expanding form, in which a construction very similar to the usual expanding brake is utilized. The drum is driven from the engine and the band is attached to the driving shaft. By forcing it to grip the drum surface, the whole is locked together and revolves as a unit, which is the desired end.

The selection and adjustment of clutch springs is a delicate matter; if they be too free, the member will not take hold, slipping will result, and the engine will be raced to get the desired speed, eventually causing much damage; if too tight, it will grip so quickly and strongly that the car will start off with a jerk, stalling the engine if let in too quickly, and making it difficult to disengage. Truck drivers are advised to avoid tampering with the spring adjustment so long as the part acts correctly.

Similarly, with the friction surfaces: These should take

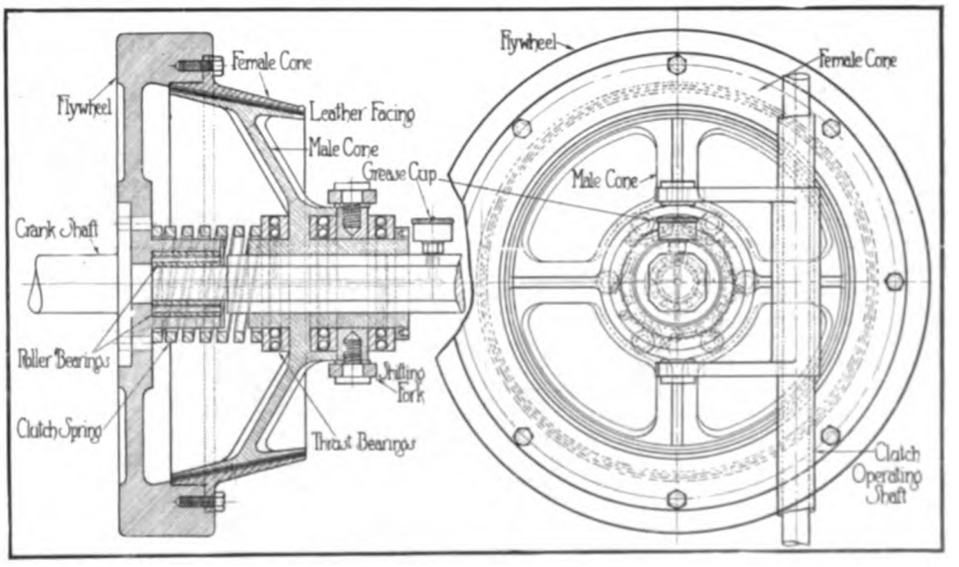

Fig. 57—Standard Type of Inverted Cone Clutch with Enclosed Spring, But External Adjustment, Used on Mack Trucks—Operating Fork at Right.

Digitized by Google

hold easily, gently and progressively, but once gripped together should hold right up to the ability of the engine. If slippage result, the surfaces may be too greasy or the leather or other facing may have become oil soaked. When this occurs, it is well to take the member out, clean the surface as much as possible, then soak over night in water. Follow this with a thorough cleansing, using gasoline, and it will be ready to replace. While the part is out of position, roughen the surface with a coarse file. For the first few days, a fine powder may be put on the surfaces, but sand or any gritty form should not be used. The use of powder is inadvisable except as a last resort.

Ed. Note—The next installment will take up the different forms of devices for varying the speed, showing the need for these, the types usually encountered, a number of common forms and their operation.

MILLER'S ADVANCE CATALOGUE.

Those who have come to rely upon the catalogue of Chas. E. Miller, 97-103 Reade street, New York City,

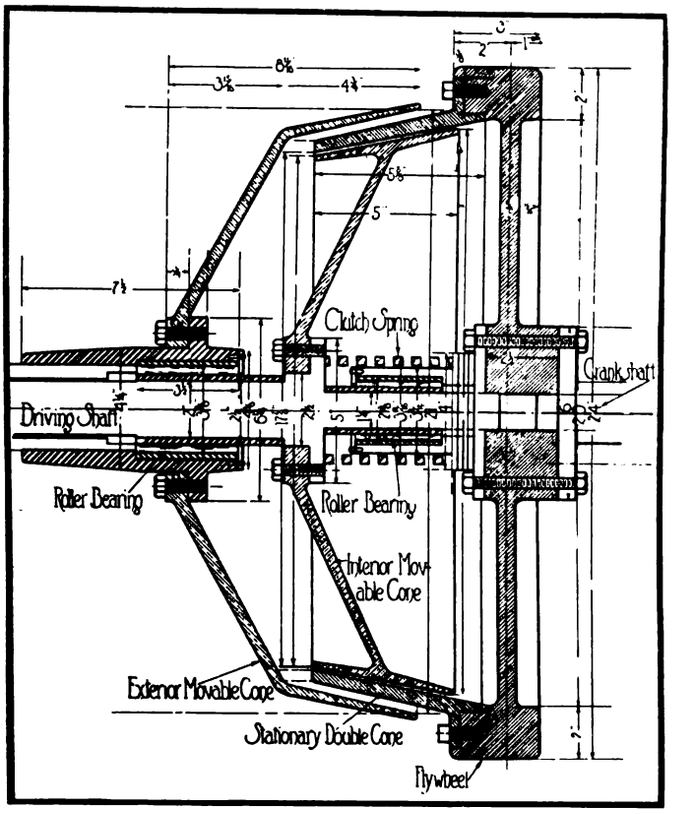

Fig. 58—Double Cone Clutch of the Inverted Type, a Peculiar Form Also Used on a Railway Car.

for information concerning automobile accessories, parts and supplies, will be glad to know that 100,000 copies of the advance catalogue No. 21, for 1912 have been printed for distribution at the forthcoming shows in New York City. As has been true in the past, this is undoubtedly one of the most complete compilations of motor car fittings ever made. The numerous stores maintained by Miller in various cities, make it extremely easy for motor truck owners to secure anything listed by him at short notice, and when it is remembered that Miller is not only a wholesaler and retailer, but manufacturer and importer as well, it is not strange that his catalogue is so complete. It is always possible to secure one by addressing the nearest store or the home office, as above.

NEW HEWITT COMPANY FORMED.

Papers have been filed in Albany, N. Y., for the incorporation of the Hewitt Motor Company, with offices in New

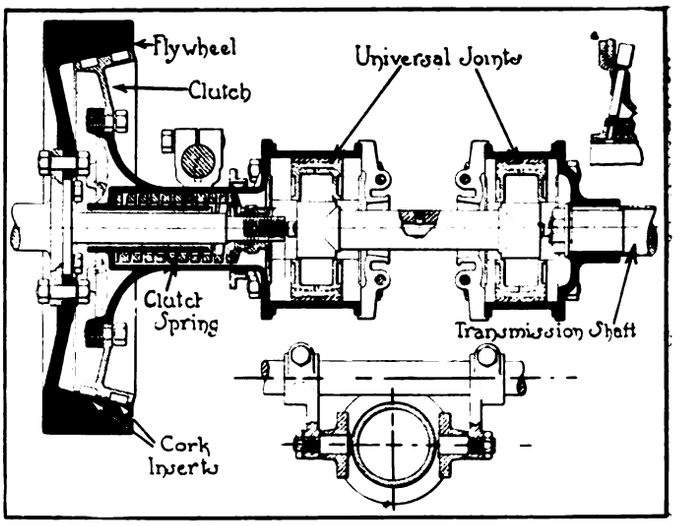

Fig. 59—Straight Type of Cone Clutch with Cork Inserts on Sampson Trucks, and Universal Joint Construction.

York City. The original concern of this name was one of the pioneers in the commercial vehicle industry, being one of the first to produce light delivery wagons and heavy trucks. In January, 1910, it was combined with the Metzger Motor Car Company of Detroit, and Hewitt trucks were sold through that concern's commercial vehicle department at 10 East 31st street, New York City, Edward R. Hewitt, engineer of the original Hewitt company, remaining in charge.

It is understood that the new company has purchased the Metzger Motor Car Company's interest in the truck end of its business, and will begin the manufacture of Hewitt vehicles under its own name at West End avenue and 64th street, about Jan. 15. The directors of the new concern are: M. F. Burns, E. C. Converse, William E. Corey, E. R. Hewitt and Ambrose Monel.

BIRMINGHAM INCREASES EQUIPMENT.

Perhaps no city in the South has given the subject of motor transportation more study than Birmingham, Ala. It will be recalled that the fire department practically has replaced its entire horse equipment with automobile apparatus, and now it appears that Commissioner Weatherly of the street department is about ready to follow its example with respect to vehicles for his work. He says the greatest item of expense is that of transportation, and if motor cars will effect the same saving in his department that they have for the fire wagons he will be justified in making the experiment.

His investigation leads him to believe that one motor truck will do the work of three teams of six mules and three drivers. While no official statement has been given out, it is understood the city contemplates the purchase of five or six automobiles for this department, one of which will be of sufficient strength and durability to handle the garbage problem of the city is a satisfactory manner.

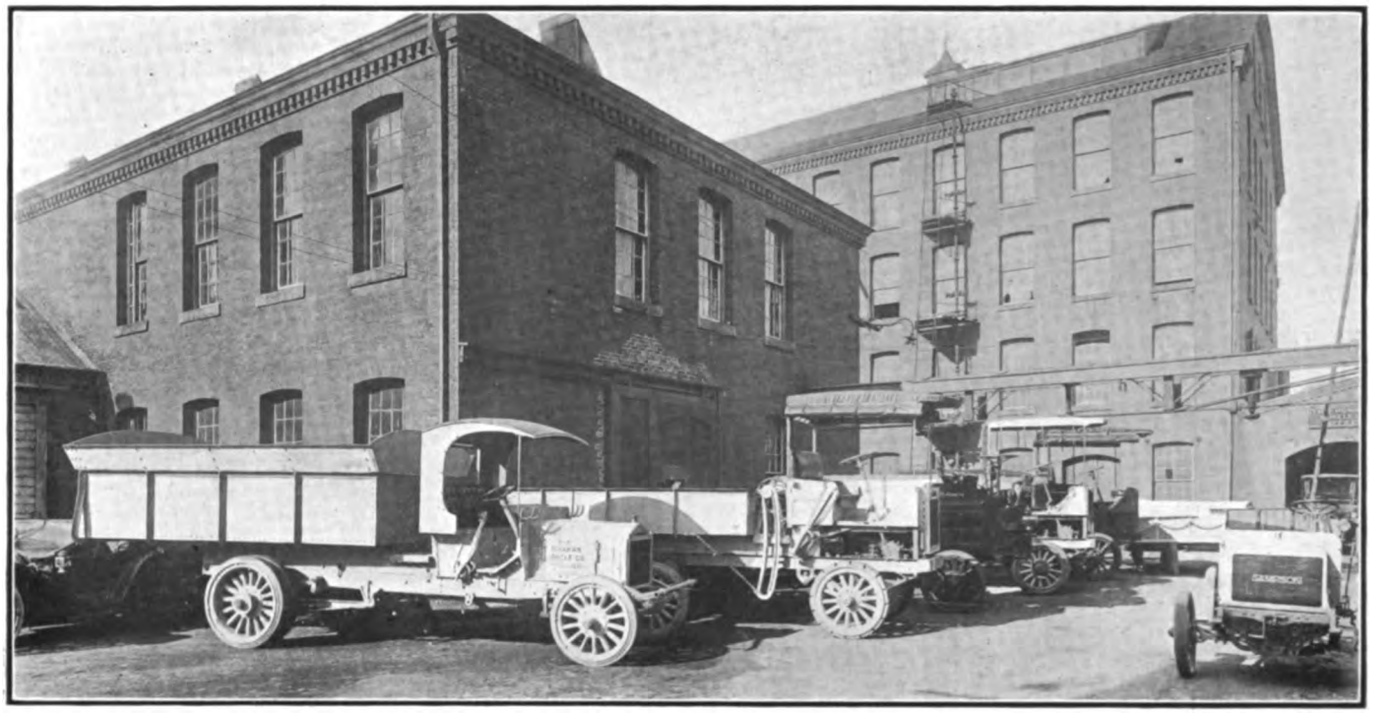
POWER WAGON BODY DESIGN AND CONSTRUCTION.

Service Vehicle Equipment Building an Industry of Large Proportions---It Requires Engineering Skill and Knowledge of Chassis Details, and Entails Specially Developed Facilities to Produce the Special Works.



(By William W. Scott.)

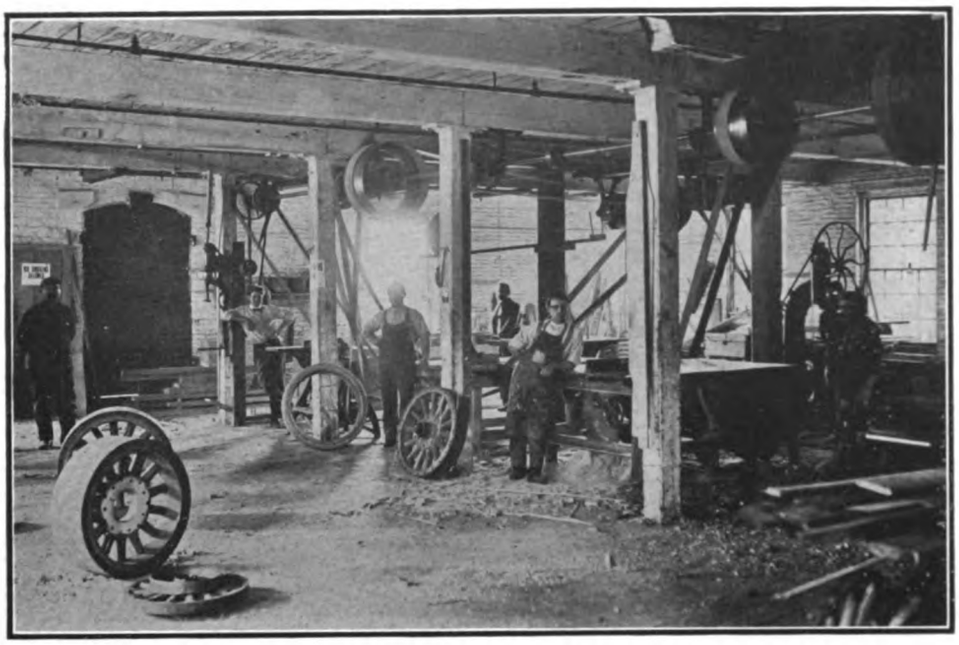
THE utilization of the industrial power wagon has made essential specialization in body construction. This has created an industry that is entirely separate from making pleasure car bodies. The possibilities it affords are seemingly unlimited. To illustrate this it may be pointed out that with the greater number of manufacturers of pleasure vehicles from two to a half dozen different bodies are used. There are others who may make a dozen or more types, but all of these are not generally stocked and some are supplied only to order. It is usual for those who produce large numbers of machines to simplify design for commercial considerations—manufacturing cheaply and to reduce the factory equipment. Those who purchase pleasure cars must select the type that is offered or pay for specialization, and special work always costs money.

The manufacturers of pleasure vehicles who began to install bodies on touring car or roadster chassis found that it was not practical to build stock bodies that would meet with approval. So many changes were demanded from the designs created that it was decidedly impossible to give the attention to special work with the ordinary facilities. Then construction to specification was adopted with hardly better results and it was realized that to serve the people satisfactorily it was desirable to supply hundreds of sizes and many designs, which could not be done without material change from the usual method of factory production.

This condition made imperative abandoning special work or equipping factories to produce it, and this led to very general recommendation that the chassis only be delivered to the buyers, they to have the bodies built by local builders who could produce these to exact requirements. Many motor truck manufacturers found it desirable to go outside of their own factories to have bodies constructed to specification and did so to secure equipment for show purposes. The European custom has been for years to deliver pleasure car chassis to purchasers, not furnishing the body unless a few standard types are demanded.

The fact that the makers of industrial vehicles have preferred to devote themselves entirely to construction of chassis, and that the buyers can secure bodies that are in every way satisfactory from those who specialize this work, has developed industries that have assumed considerable prominence. Some of these body makers will take orders for all types of construction, while others will only accept orders for wagon and truck bodies. These specialists

Power Wagon Chassis with Special Body Equipment for Widely Differing Service, Either Built or Installed by the Monahan Vehicle Company, in the Yard of the Works.



may have been wagon and cart builders, or perhaps firms that were enterprising and realized the fullest benefit from the change from the animal to motor transportation, while others may have taken up a work that has been especially promising.

While those who have adopted motor vehicles for industrial purposes realize the desirability of bodies adapted for their needs few understand that there is quite as much engineering knowledge and practise necessary to produce a good body as is needed to build the chassis. This is not intended to discount the motor vehicle engineer, but to emphasize that high class work to yield service and endure under differing conditions of use must be built from well selected materials, to correct designs and to established engineering principles. Not only this, but to give the satisfaction desired a body should be designed for the purpose for which it is to be used. It may be assumed that a single type of body might be utilized for a great number of purposes, which may be true, but this could only be applied to instances where the work differed as in general haulage, and where an equipment is with reference to diversified service.

It is not to be assumed that body building has been

Digitized by Google

fully developed. As a matter of fact the progress, so far as power wagons are concerned, relates to the requirements of a small proportion of those who have utilized highway vehicles for business. It is rare indeed that stock creations

Section of Woodworking Department, Where the Rough Stock Is Cut and Formed for Body Components to Specification Requirements.

are produced. With few exceptions the bodies built have been to meet the needs of individuals, the ideas being developed by practical designers and builders.

There is in service construction much opportunity for creative work, but ornamentation gives way to simplicity, for at most paint and varnish can only please the eye and add nothing whatever to productiveness. It is not possible to construct a stock of bodies and to deliver one or more when a customer makes demand, because there is usually so much variance. Not only this, there are quite as many differences in the chassis as there are in ideas, and it would be the height of folly to attempt to sell what is not wanted at a price but comparatively little less than what would be charged for a special order. What is wanted in a body is, as a rule, substantiality and capacity, and yet it must have an appearance that is not unsightly when contrasted with all or many other types.

It may be emphasized here that there is with many a desire to have what will attract public attention because of the advertising benefit that may be derived from the constant use of vehicles in a community. Just what this value may be is decidedly uncertain because there can be no measure applied to it. There is no question that public opinion is always desirable, but prestige is mainly sought by those who do business, and this means favorable comment. This develops the fact that the body builder who would please and attract patronage must be able to produce what will have every desirable quality of other forms of vehicles, be sufficiently original to develop what will serve all other purposes as well, and yet be governed by competition so far as the price is concerned. Not only this, some men desire to incorporate in the one vehicle what will give them equipment for widely varying service, and to meet such requirements impels careful study and a knowledge of fittings and accessories. As an illustration, frequently a demand is made for a combination that will afford both freight and passenger service, or for the transportation of two forms of commodities, such as grain and lumber, or contracting materials, or coal and merchandise.

An example of the development of body building to specification is illustrated by the Monahan Vehicle Company, Providence, R. I., which has for several years built bodies for power wagons and trucks, and which has distributed its products all over the country. This concern was originally engaged in constructing animal vehicles, generally of a business character, and with the adoption of the automobile to industrial purposes demand was made for bodies, for the first machines to be used had been given more or less service for pleasure. This necessitated the creation of whatever would meet the requirements of the owners of the chassis, within the limitations of the original construction, though it was often necessary to make material changes and modifications in the ideas originally outlined by them.

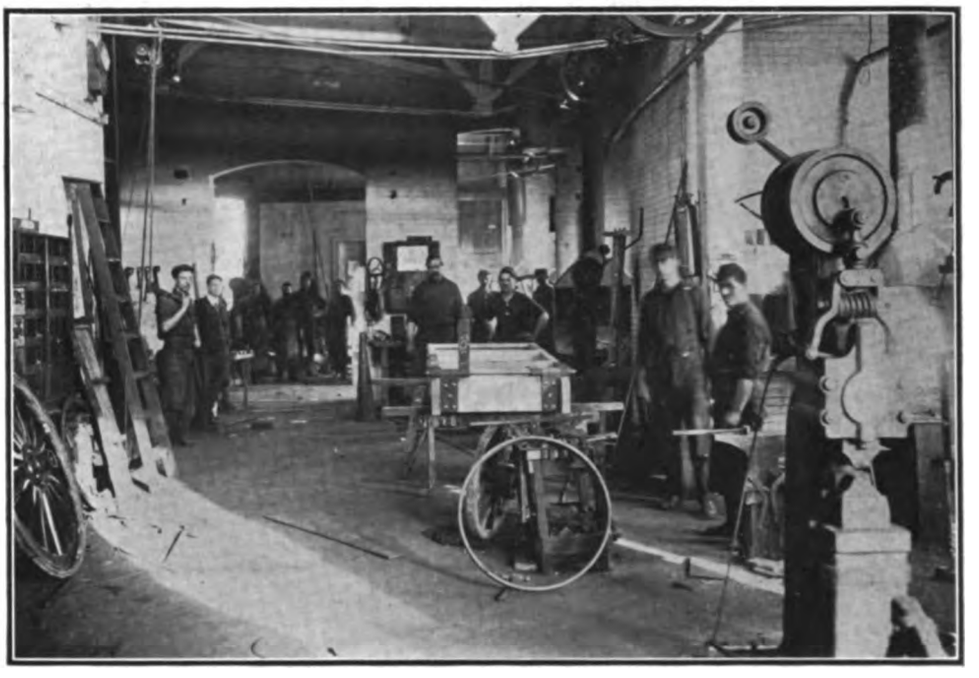
This work was largely of an experimental character because of the lack of knowledge of service conditions and with no experience save with animal conveyances. With this foundation other work was undertaken. The production of power wagons was begun and this created a demand for special bodies for varying purposes. The total of differing demands made upon the concern in the period it has engaged in this work is not certain, but it is safe to assume that in all considerably more than 100 different

Another Wood Working Division, Where the Body Parts Are Finished and Each Job Is Made Ready for the Assembly.

designs have been produced. The exact number would be interesting to know, but as it now does business the company has catalogued no less than 40 different designs in 149 different sizes of body which are classed as regular

Digitized by Google

or standard products, all of which may be fitted to all pleasure and industrial chassis. This, however, does not represent the possibilities of construction, for the concern is prepared to undertake whatever may be desired. While the number may seem large it may be said that this does not represent by any means the extremes of the demand for service machines, and it is well within probabilities to state that there are at least 500 bodies in use that may be regarded as business types. This is a far greater number than is to be found with pleasure vehicles, both horse and motor conveyances.



Besides these the company produces bodies that are designed for heavy work and it has recently turned out a number of equipments that are for exhibition purposes. These will be seen at all of the principal shows this winter. Some of the bodies are of wood, some of metal, some combinations of the two. The capacities range from 1000 to 16,000 pounds, and it might be said that the only limitation is the proportions of the chassis.

The first consideration in body construction is the use to be made of the vehicle. No matter how experienced a man may be with his service and how carefully he may have planned he lacks the knowledge of actual body building that is essential in establishing even fundamentals. As a matter of fact it is often best for a man to consult a body building firm just as he would an architect when he desires to erect a house or building. He may know what he wants in a general way, but to secure the best that is possible with the limitations of the chassis becomes a problem that cannot be worked out without exact knowledge of the service, the highway conditions, the character of the loads and the construction of the chassis itself.

To illustrate this an instance may be cited when the first truck chassis produced by a leading manufacturer was purchased by a very large concern and the purchaser decided to have a body built by the Monahan company. An executive visited the works and described in detail what he wanted. He asked for an estimate and was seemingly disposed to dismiss the subject with his description and his broad order. The designer of the firm noted the desires and inquired fully into the details of service. Then the chassis was examined and its dimensions learned. With this a body was designed that, when submitted, was pronounced by the manufacturer to be exactly what he wanted, but as a matter of fact it was in every way different from what had been described. Not only was it impossible to build what had been first ordered, but from an engineering viewpoint it would not have endured. The designer learned the requirements and then adapted them to the chassis with exact knowledge of materials, construction and the service, producing what was also sightly and substantial and a fitting combination of dignity and serviceability.

In industrial service it is often necessary to create what will be a combination vehicle, that will serve for more than one purpose, and sometimes these purposes are so widely different it would appear that desirable results can only be obtained by sacrificing essential qualities in either. It is not the owner who is qualified to decide such propositions, because he does not understand the limitations and the possibilities. It is also a fact that the makers of the chassis do not construct them with a view of extremely diversified service. It is true that chassis are built for differing purposes but the measure of capacity is by load only, not by proportions. Then in making installations to meet the desires of the purchasers it is necessary to be governed by certain mechanical conditions. Were it possible to take a chassis of a given make and capacity and lengthen or shorten it, or make it conform to body proportions, that would be ideal from the viewpoint of the purchaser and the body builder. But as a matter of fact such changes are rarely possible and the body builder must produce what will best serve the purpose of the owner with reference to the limitations, for with the majority of the manufacturers changes in the chassis would nullify the guarantee, and the guarantee is one of the strongest arguments that can be made by the builder for the sale, and by the purchaser for the purchase of the truck.

It is apparent that no such conditions govern the construction of the animal vehicle. There is nothing to be considered save the storage space or the area in which it is to be loaded or unloaded. The limitations as accepted for animal vehicles by manufacturers are generally established by the makers of components, such as axles, wheels, and the like. With purchasers the capacity is gauged by custom or by supposition. The metal work is designed for bracing and strengthening the construction without particular reference to anything else than endurance. The wood work is cut to pattern and assembled with service as the chief essential. So far as design is concerned any work may be varied to serve any requirement and there is no prohibition as to adaptation. With manufactured vehicles certain types are selected as best meeting with the demands of the people and these are built in such quantities as the market justifies. These are carried in stock as standard products by vehicle dealers.

Looking Through One Side of the Blacksmith Shop, Showing the Tool Equipment and a Bolster for a Pierce-Arrow Truck to Have a Five-Ton Dumping Body.

While it is certain that there eventually will be as largely diversified production of mechanical industrial conveyances as there has been in some instances manufacturing of animal transports, it is equally certain that there will be a very large number of chassis makers who will entirely divorce the body work, even for their own service. It does not require more than casual observation of conditions and needs to establish beyond question that pleasure car chassis building and body construction are being more widely separated each year. While the business of the one governs the other it cannot be denied that the two are separate industries.

There are those who demur at paying the prices demanded for special body work. It is held by them that there should be the same relative cheapness to be found in stock productions. The contention is made by men who do not hesitate to pay well for animal vehicles that because an installation must be made on a chassis that must be

Digitized by Google

bought outright the first cost of a body is high. As a matter of fact such is not the case. The chassis is sold without equipment and in competition. To the price of the chassis must be added the value of whatever body will serve, and this body would cost the chassis manufacturer no less, and probably more, than it would were it built by the exclusive builder. Any custom work must of necessity cost more than what is manufactured in quantity, but there is not the usual wide difference between the two to be found in motor wagon body building.

While this difference would exist were each body a separate creation and were each designed especially it is apparent that where designs have already been made, which may be utilized, or slightly modified to meet requirements of the customer, the exclusive body maker is prepared to give the benefit of his experience and facilities at what may be regarded as moderate cost. The body making firm is as a rule better prepared to give service than is the chassis builder, for with it design and construction have been developed and perfected, while with the chassis manufacturer the body equipment is secondary and, as a matter of fact, it is often to order from body builders who are compelled to charge special prices for what is justly regarded as purely custom work.

There are in the United States nearly 200 different enterprises building service vehicles and these produce from one to nine different types of chassis. A list of 50 of the leading concerns recently analyzed shows that these firms built at the time the compilation was made 150 different types, or an average of three each. It is not to be assumed that all of these, if fitted with standard bodies, would meet the requirements of the purchasers. As a matter of fact of the number stated 13 built one type only, 10 two types, 11 three types, six four types, five five types, three six types, one eight types and one nine types. One may imagine the diversity of demand upon the maker of one chassis that may be suited to many forms of transportation should he construct bodies for all purposes.

It undoubtedly is a fact that there is no limit to the variance of requirements when each purchaser selects what he desires. There may be limitations, but these are not often considered or regarded, so far as conventionalities are concerned. There is a desire characteristic of human nature to improve whatever is brought to one's attention, or to make adaptation to one's use. It is this that has caused the demand for differing creations, and it also is a very human desire to be satisfied.

But, as has been pointed out, it is quite impossible to have every requirement within the construction possible on a single chassis, and furthermore it is not possible to take a chassis and change it to permit the installation of a body such as might be wanted. Then obviously the one means open is to purchase the chassis that will nearest meet the dimensions of the body required. Then comes the matter of expense of chassis and the cost of the body, to say nothing of the transportation charges.

As the subject of body building is considered it is obvious that there are some types of chassis that more nearly meet with the recognized standards of body builders. It is possible that in the designing of these chassis more attention was given to the probable uses and the demands of the purchasers, and some thought may have been devoted to the problems of the body designer. It is seldom, however, that a power wagon chassis is bought with an idea of it being particularly suited to the design of body with which it is to be utilized. It is hardly necessary to point out that durability and economy of operating expense are the essential factors that influence the majority of the men who buy mechanical transports. Often decision is reached only after careful consideration of every phase that has presented itself, and then it is found that the most vital quality, that of body installation, has been overlooked.

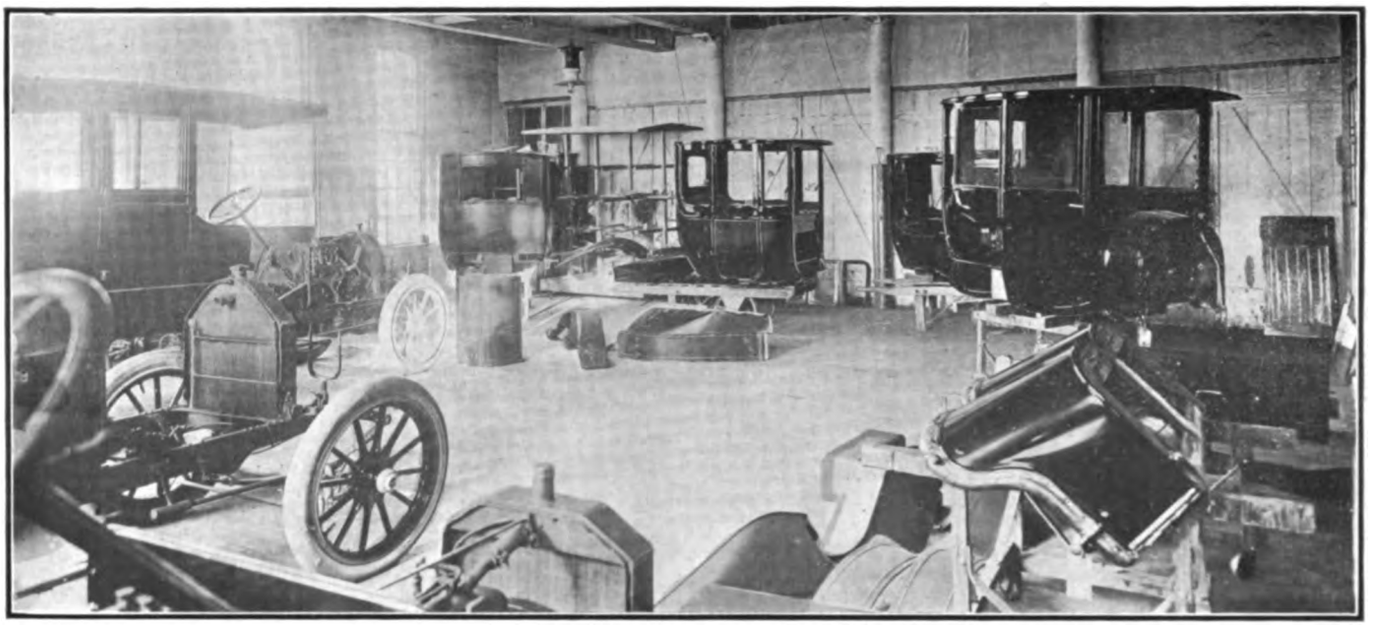
A Glance Through a Corner of the Trimming Department, Where the Upholstery Is Cut and Made Up and the Tops and Curtains Are Made Ready for Installation.

This oversight may be from the ignorance of the owner, the neglect of the agent to give the body the attention this detail deserves, or the assumption of the buyer that a manufacturer or body builder can make any provision whatever to meet requirements. It is extremely probable that the average maker of bodies is better versed as to the possibilities of each make of chassis than is any given chassis builder, and were a purchaser to consult a body maker before the purchase with reference to the possibilities of the chassis some exceedingly useful advice might be obtained.

As has been stated the buyer has need of specific service as a rule and in the selection of a machine will perhaps follow his own judgment, or may be guided by the experience and advice of others. Let us assume that the chassis is designed with the greatest care and that it is constructed with reference to design. Every component is proportioned

Digitized by Google

with knowledge of the requirements up to maximum load and a reasonable margin of safety is provided. But the chassis ought to be used as purposed by the designer. The load must be carried with the weight distributed on the chassis and on the tires as was designed, for were the freight not so carried there would be undue or unequal stresses on differing parts and weaknesses might be developed.



This statement has been made because the subject of the chassis is first, last and all the time, and the design of body equipment is dependent upon the chassis and its arrangement. The statement has been made that engineering skill is just as necessary in correct body building as in the production of the chassis. This may be emphasized by pointing out that a mechanic may produce a motor vehicle, and the same man may build its body, but neither will be as finished nor as satisfactory as were they constructed to recognized detail and by adequate tool and machine facilities. Nor will either be as acceptable when offered for sale.

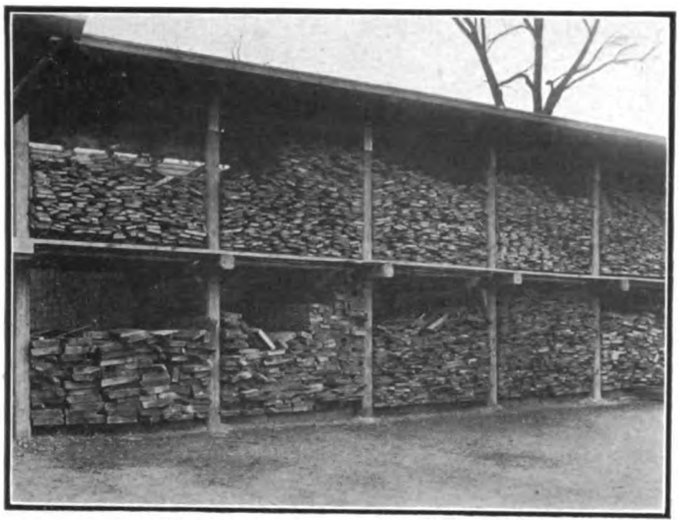
While the usefulness and value of a chassis may not be affected by the character of the body installed upon it its serviceability will depend to a large extent upon the form of the equipment. Obviously then it is desirable to have what will give the greatest measure of service. In bodies in which but one purpose is to be served it is not difficult to determine what form will best be adapted to requirement.

Body building for power wagons as an industry means that there must be factory facilities, but not of the same character as were pleasure cars produced. Where several types are standardized, as with a complete automobile plant, or where many types are built in large numbers, as in an exclusive car body establishment, manufacturing methods to standard patterns and templates and by specially fitted machinery must be adopted for economy and profit. This means that the work is departmentalized, beginning with a drafting room, where the bodies are designed, or where the working drawings are made, and including the wood working divisions, the tin or metal working shop, upholstery and the painting and finishing rooms, each as complete as may be required by the character of the work produced. With these after a design has been determined the body is completed according to a regular working schedule and it becomes merely a manufacturing proposition.

So far as detail is concerned a body is created to have certain appearance and is to specification. Each is assumed to be equally good and to differ not at all. Where there is special work this may apply to a change in color, or perhaps in the tone of the leather upholstery, or possibly a monogram or design is placed on a body, but the work and materials are identical. While the number built may be one or 50 a day there is no change made so long as this type or types are turned out, and it may be that one change a season is all that is made. As a matter of fact in some instances the same type has been made for several years. It is certain enough that manufacturing under such conditions means minimum of expense and uniformity of work, two excellent factors from a business point of view.

The power wagon builder must have even greater facilities than has the body factory, for each work turned out is in itself a separate order. This in a nutshell shows why it is that the cost of the service body is necessarily more than where bodies are manufactured in considerable numbers. The plant must be sufficiently large to undertake whatever commissions are received. It must have a drafting department and capable men must be employed who are competent to produce whatever is desired. They must have greater and more diversified experience than those engaged in ordinary body manufacturing and not only have a careful engineering education, but be familiar with the design, construction and requirements for each type of chassis upon which they are called to work. This means that they are specialists in every sense and capable of taking any problem of vehicle design, including both chassis and body, and successfully solving it. This work is broader than that in which the motor vehicle designers are engaged because it is not one but a succession of problems in each of which economy, service and appearance are all important factors. As must be evident these men are not easily secured, for there is no education that will fit them and their knowledge must be gained from experience.

In the Painting Shop, Showing Bodies and Chassis in Varying Degrees of Finishing, These Being all Pleasure Cars.



After the designing or drafting room the facilities must be complete in every way. First is the wood workers, where workmen must be capable of taking a blue print and from it forming the different wooden parts, not to patterns or templates, but to engineering dimensions. In this work the men necessarily must be of experience and capacity. It may be that these men will have for months no work that is in duplicate. Such work is not as rapidly produced as is one series of parts, despite experience and high class facilities.

Next is the machine shop in which all special iron and steel work is produced, this from the parts in the rough or by adapting whatever of the constructions may be available. The machinists must be skilled men who can undertake any job and do it well. They must have ample facilities. The work may be for the heaviest truck or for the lightest and most artistic construction.

The third department is the blacksmith shop, one of the most important, because each work requires special construction, differing in size and form, and shaped from iron or steel, which must be produced by hand. These men must

Digitized by Google

be able to take a blue print and make whatever has been designed to exact proportions, just as are the wood workers. So capable are skilled men that they can from drawings make what may be installed without fitting. The extent

Stock of Selected Wood for Body Building, Each Kind and Thickness Being Separated, Showing Quantity Required for Ordinary Needs.

of the blacksmithing necessary on a truck body is seldom realized until it is collected for installation. All smith work must be finished that it may be painted and varnished, and this necessarily requires time in addition to the forging.

Next are the metal workers, for bodies may be of wood or combinations of wood and metal, or of metal alone. These men must also have large experience and be qualified to do any job. This applies to all classes of metal from tin to aluminum, from delicate brass sheathing to heavy plates of steel for bodies for coal and similar haulage. The equipment must be not for one class of construction but for everything that occasion may demand.

In every department the tool equipment must be sufficient to meet with every demand. Naturally every machine cannot be constantly productive, which is another reason for cost.

The upholstery and trimming department must be equally specialized and the workers must be capable of doing any job to a standard and in keeping with any particular effect sought. In this work the materials are cut to special patterns and these generally differ. This department makes the seats, cushions, backs, lining, tops, curtains, shields, dust covers, hoods, boots, etc., together with work to meet certain ideas not usually applied.

The painting department must be able to handle anything, this ranging from a simple coat of lead to the highest finish that can be applied, for some of the bodies are given as careful attention as though intended for ornament instead of service. The workmen must be broadly experienced. The decorators must be artists, for frequently painting of high class is executed on bodies that must bear close inspection but endure under the severe climatic changes. Men of this class command large wages and their work is exceedingly varied. The facilities for work must include dustless rooms that are well lighted and space to handle any reasonable number of jobs.

The supervision of the work is necessarily exacting and requires men of unusual ability, for each job must be given detailed attention and nothing can be neglected. No contract can be systematized, and consequently construction must be without regard to the usual methods of manufacturing. From the arrival of the owner of the chassis, or his correspondence, each body constructed is a separate order and as such must be given a care in production that would ordinarily be devoted to an original in a body manufactory. The inspections must be frequent and thorough and each process or stage followed by the designer to make certain that the specifications have been met.

It will also be seen that in designs that are original construction cannot be experimental, and where special service conditions are to be dealt with safety entails a large margin of strength. This requires a considerable excess of stock as compared with what might be believed, and material selected for heavy work must be of the best to be enduring. With the large builders all metal bodies are frequently ordered and some produced are of steel, this requiring workers who can undertake such construction. It is exceedingly probable that this type of body will eventually be adopted for many vehicles, for it undoubtedly has greater endurance and is less susceptible to average conditions of service.

Each special body builder must have a stock of material that will meet with any requirement. Ordinary lumber will not serve and what is generally used is high class, although the difference may not be apparent in the rough stock. The sills, posts, crossbars, bolsters and the like must be of fine, hard wood, and the panels must be material that will endure similarly. It is not unusual to use wood that

Another Section of the Painting and Finishing Shop with Pleasure and Service Vehicles in Differing Stages of Completion.

Digitized by Google

costs as high as 25 cents a square foot when purchased, and 15 cents a square foot in the rough is a common price. This is for lumber of an inch or less in thickness. The stock must be carefully selected and some firms have standing orders for certain material with dealers who deliver whatever is available from each lot received. The wood is carefully stored and protected and for each work it is picked to meet the specifications. To maintain a sufficient quantity of well seasoned lumber is a problem of considerable proportions for it is becoming higher in price and more difficult to obtain each year.

Regarded in the light that has been given it appears that there is abundant reason for the cost of special bodies, and that those who have purchased stock animal vehicles cannot base judgment as to prices upon the valuations they have paid for such equipment. It also is apparent that to give the same class of work to their customers the chassis builders would have to maintain facilities of large proportions.

The accompanying illustrations show some of the departments of the Monahan Vehicle Company, Providence, R. I., which is widely known as a specialist in motor vehicle body construction. These are working pictures and show conditions as they have been found during one day's activities. It is not to be assumed that it is possible in pictures of this character to give a clear idea of a day's work, but it does demonstrate the character of facilities that are necessary, and that the statement that such an enterprise is an industry apart from but allied with the general proposition of motor vehicle building is well founded.

These views do not show the drafting room, the office, or the stock rooms, for it is necessary to carry a considerable value of standard parts such as nails, bolts, rivets, nuts, screws, pins, wagon and carriage parts and fittings, rims, tires, hardware, upholstery and trimming materials, paints, colors, varnish, brushes, gold leaf and decorative stock. While it might be possible to purchase such material in small quantities this obviously would not be economical.

One of the most important departments is that in which is kept the drawings of every vehicle and vehicle body produced, so that it is possible by records to refer to any specific job and to illustrate the possibilities with any chassis that has been dealt with in the work produced. This series of drawings naturally covers a large number of types, but it does not cover every machine that has been built.

Ed. Note—The following articles of this series will take up systematically varying types of bodies and their design with reference to differing service conditions, illustrating them with practical constructions now in use.

NEW DEMOUNTABLE SOLID TIRE.

A new demountable solid tire, the feature of which is that by its use both single and dual equipment can be changed without removing the wheel from the vehicle, has been brought out by the United States Tire Company, New York City. The device should appeal to owners of commercial cars as replacements may be made by any ordinary workman in less than one-half the time required with styles that heretofore prevailed. While there are forms possessing demountable features which admit the removal of the tire without taking off the wheel, the new product is said to be the first applicable to both single and dual members.

It meets with all requirements of specifications adopted recently by the Society of Automobile Engineers and will be known as the United States standard demountable. The demountable features are possible through making the inside diameter of the tire band .375 inch greater than the outside diameter of the wheel. For example, that of a 36-inch tire is 30.375 inches; the outside diameter of the standard wheel for a 36-inch tire is 30 inches. This additional size gives a clearance between the tire band and the wheel band of .1875 inch, all around the circumference, which clearance makes it impossible for the former to rust or freeze to the latter, as they do not come in contact.

Into this open space wedges are forced which are a part of the flanges, pulling them in and making a good tight joint by the use of bolts running through the felloe. These wedges are of a 20-degree angle at the top and flat on the bottom. The top of the wedge comes in contact with a corresponding bevel on the underside of the tire band, forming a seat and giving metal to metal contact of about .75 inch on both sides of the tire. These wedges are so designed as to remove all strain from the bolts.

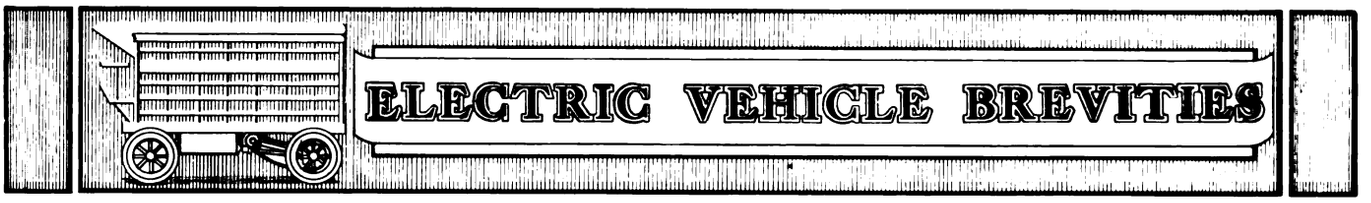
The action of the weight on the tire is to press the flange wedge directly onto the wheel band and as it seats there flat, there is no tendency to spread the flanges. The equipment for a single tire is an outer flange wedge, an inner member and nine, 12 or 15 bolts and nuts, depending upon the diameter. That for a dual wheel is the same with the exception that it has a centre wedge in addition to the flange members.

All the latter are split which allows them to be drawn up tight and permits of greater variation in the circumference of the wheel. The holes through these flanges for the bolts are elliptical and the difference between the outer and inner edge flange lies in the fact that the latter has oblong, square cornered bolt holes and the outer has round cornered elliptical openings. Those in the inside flange are square so as to hold the square shank of the bolt and in this way prevent its turning.

The tire itself is made exactly as the Continental solid form, produced in Hanover, Germany, and is built on a steel band with a layer of hard rubber between the band and soft rubber tread. The band is of a high grade steel, .5 inch thick with a serrated periphery so as to form a dovetailed seat for the hard material, giving this joint additional strength. After the band is cleaned thoroughly, the hard rubber is laid around it, being forced into the serrations, and the soft material is then fitted. The tire after being cold pressed is vulcanized in one heat, making a solid mass from tread to base. It is constructed in accordance to the size adopted as standard by the S. A. E.

Several have been on test cars for some time and one was examined after 5200 miles of service and found to have worn but .375 inch.

LOCOMOBILE ANNOUNCES NEW MODEL.



Among the new vehicles to be shown at the coming display in Madison Square Garden, New York City, will be a five-ton truck produced by the Locomobile Company of America, Bridgeport, Conn. The concern is said to have been working on this model for the past two years and to have incorporated several new features in its design. The power plant is a four-cylinder motor with bore of five inches and stroke of six, with four-speed transmission and chain drive. The driver's seat is located over the engine.

Last summer one of these machines was subjected to a severe road test after which it was disassembled to note any undue wear. Loaded with 6.5 tons it was driven 9000 miles, three test drivers taking turns during the 24 hours' continuous service. The subsequent inspection failed to develop any defect.

WHERE COMMER TRUCKS ARE UTILIZED.

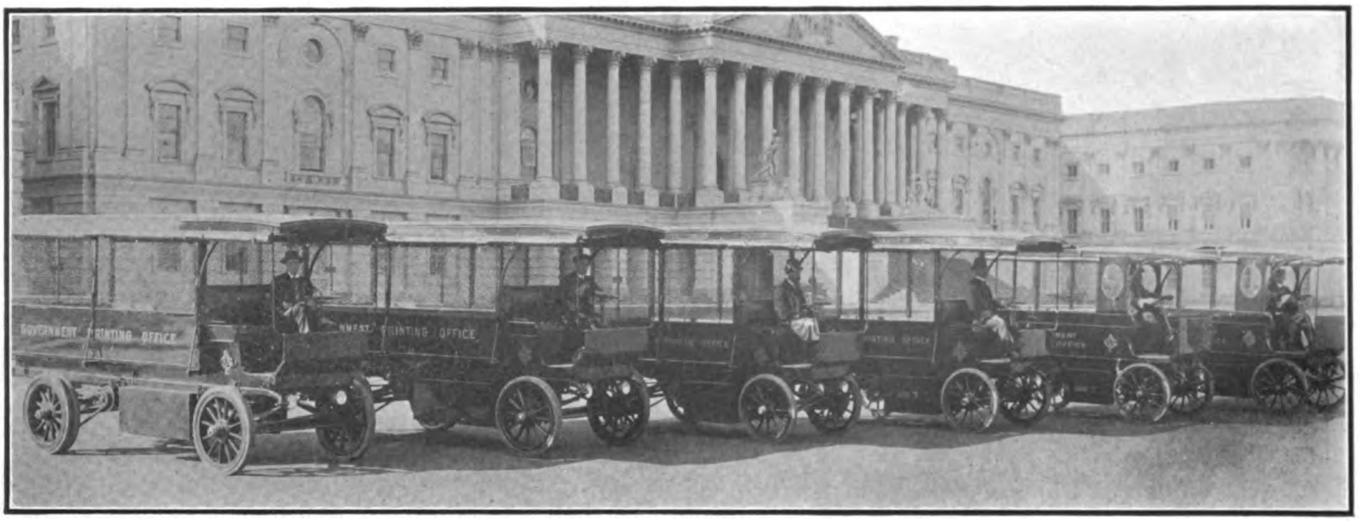
During his recent visit to the Kingston, N. Y., plant of Wyckoff, Church & Partridge, Inc., New York City, maker of the Commer trucks, H. C. Underdown, managing director of the Commer plant in England, spoke of the number of these machines in service in the various countries of the world. In addition to the large number being operated in London by various industries, the British war office has adopted the Commer after trials lasting over two years. The Russian war office owns several of these vehicles, one of which won the gold medal in the official trials of 1910. In Calcutta, India, the fire brigade has given repeat orders for two years, while orders have been filled in the Argentine Republic, Patagonia, Peru, and other South American countries, also in Russia, the Penang Peninsula, South Africa, Colombo and Ceylon. In Australian centres there are more than 150 of the automobiles in service. Mr. Underdown expressed great satisfaction at the wide distribution of Commer cars in this country through the efforts of Wyckoff, Church & Partridge, Inc.

Digitized by Google

Few people, even those in the automobile trade, have an adequate idea of the number of electric vehicles utilized in the brewery industry. The General Vehicle Company, Long Island City, N. Y., has compiled statistics which have been incorporated in a neat booklet and circulated among the brewers. This company recently passed the $1,000,000 mark in sales which is a new record for machines delivered to breweries.

According to the booklet, 67 different breweries are using General Vehicle electrics, of which number eight have no less than 196, or an average of 24 trucks each. Over 200 are of the five-ton capacity, besides scores of 3.5 and two-ton trucks. Each five-ton keg vehicle has a capacity of 50 full half-barrels or 75 to 100 empties, while the 3.5-ton bottle automobiles have a capacity of 110 cases of two dozen pints each.

It is estimated that the breweries of the world employ not less than 100,000 horses, which is a fair field for displacement by the mechanically propelled vehicle. It is also pointed out that the machine has 100 per cent. greater daily efficiency than the best horse and that the life of the former may be made almost perpetual, whereas that of the animal is limited approximately to about four years.



Attention is called by the company to the fact that some of the veteran trucks have been in service over 10 years, and many improvements have been made in models in recent years. By replacing wornout parts as required, and by giving each machine proper care, users may charge off as low as 10 per cent. a year for depreciation, as against 25 per cent. for horses.

The booklet states: "The motor truck did not become a success from the standpoint of either efficiency or economy until makers realized after expensive lessons, that commercial cars must be built on a business car basis. Sales today are increasing at a rapid rate because the business world realizes the passing of the horse and because so many automobiles are making good in their respective fields. They earn money for their owners because they save it.

"A few years ago a brewery of New York City employed over 120 horses, a large number of heavy wagons and had no automobiles of any kind. In March, 1909, after experimenting with a General Vehicle electric truck the concern ordered a second machine and soon after purchased six more. A year later a repeat order for 18 was given, and the concern now operates a fleet of 30 with six more ordered.

"According to the superintendent of the brewery the machines have effected a saving of $25,000 a year. The number of horses has been cut to 50 and business has increased greatly. Half of the stable, which was 200 by 100 feet, has been remodeled and is being utilized for a bottling plant and shipping room. Back of this was a wagon yard, and in this space a garage 100 by 85 feet, and two stories in height has been erected, accommodating 48 trucks. Plans are being formulated for a garage to store 96 of these vehicles.

"The $25,000 is based on a saving of $833.33 each on 30 trucks as compared with the former horse equipment. It cost the concern 33.7 cents a barrel under the horse system and the company maintained its blacksmith and harness shop and all other equipment which accompanies such a large installment. After figuring all costs of the automobile department for one year, such as tire and battery renewals, current and other maintenance expenses, it was found that 20 trucks were delivering beer at a cost of 24.75 cents a barrel, an actual saving of 8.95 cents, as compared with the horse drawn equipment. This saving is not claimed where one machine is in service but of 20. In very hilly districts, or where the streets are in poor condition, this undoubtedly would be lowered and the expense of horse drawn vehicles also increased. But even if cut in half the economy effected would still be nearly five cents a barrel."

Fleet of Baker Electrics Recently Delivered to the Printing Office of the United States Government—The Carrying Capacities Range from 1000 to 5000 Pounds.

★

The transportation of printed matter, the product of the printing office of the United States government at Washington, D. C., is by commercial automobiles and in the accompanying illustration is shown a fleet of electrics recently delivered by the Baker Motor Vehicle Company, Cleveland, O. These machines consist of two delivery wagons, two light, and a like number of heavy trucks, with a carrying capacity ranging from 1000 to 5000 pounds.

The smallest machine is propelled by a motor, which is series wound, hung on a tubular bar across the frame in front of the rear axle, and current is furnished by a 42-cell Exide battery of 84 volts and 24 amperes. A continuous torque type of controller affords five speeds forward and three reverse. Final drive is by double side

Digitized by Google

chain and one set of expanding brakes is fitted and these act on the rear wheels, which are 34 by three inches fitted with solid tires. The steering wheel is at the left. Semi-elliptic springs are employed both front and rear.

The one-ton vehicle is equipped with an 84-volt 28-ampere battery, and has a wheelbase of 92 inches, and 34 by 3.5-inch tires. The larger automobile has an 84-volt, 42-ampere battery with a 120-inch wheelbase, and 36 by 2.5-inch solid tires are employed. The other chassis details of these cars are the same as those of the smaller vehicle.

★

The Kentucky Wagon Manufacturing Company, successor to the Electric Vehicle Company of Louisville, Ky., is constructing and marketing a large number of 600 and 1000-pound capacity electric delivery wagons and in the illustration herewith is presented one of the former type. It is propelled by a 30-cell lead battery and the mileage is estimated at from 40 to 50 with a maximum speed of 12 to 15 miles an hour fully loaded. The complete specifications and descriptions of this vehicle will be found elsewhere.

★

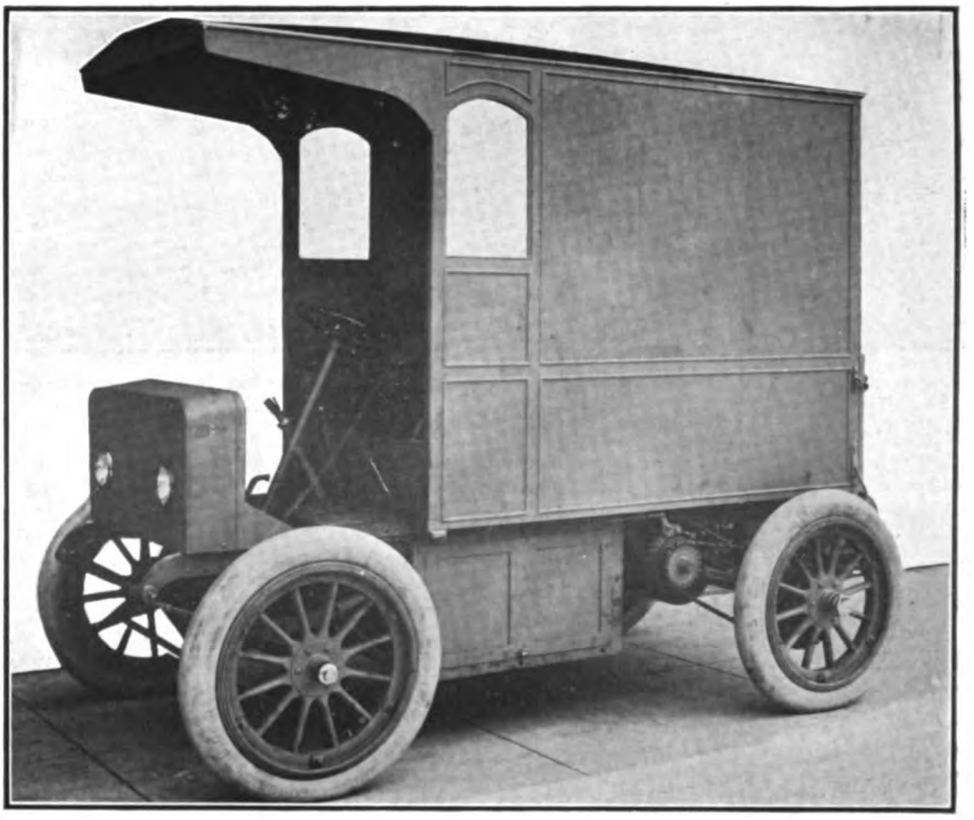
A remarkable mileage on one charge of electricity is credited to a Fritchle automobile which covered 110.9 miles recently. The car carried four persons and was run on the third speed nearly the whole distance. It was operated by M. Francis Eagan of Flatbush, Long Island, N. Y., who started the machine at Prospect Park, and the course was on the boulevard to the ocean front and return, each lap being about 11 miles.

The battery is a 32-cell Fritchle and the machine is made by the Fritchle Automobile & Battery Company of Denver, Col. A knife switch controller is utilized providing five speeds forward and three reverse, and the drive is optional, being either shaft or chain. The motor is compound, hanging from the body, and the maximum speed is rated at 22 miles an hour.

★

That the electric vehicle is capable of longevity and of rendering efficient service is demonstrated by a report of the General Vehicle Company, Long Island City, N. Y., which states that one of its machines has been in continuous service with the American Tool Company of Boston since January, 1906. During the first two months the vehicle met with an accident strictly outside of the running of the automobile, which laid it up two days. It was again placed in commission and has been doing its full quota of work every working day since, summer and winter, covering a period of over five years during which time it was not even painted. July last it was overhauled and painted and again placed in service. This is a remarkable record for a commercial vehicle.

★



A striking example of the efficiency of the electric motor as utilized in pleasure and commercial vehicles is noted at the factory of the Waverley Company, Indianapolis, Ind., where one is employed to drive an oil pump which forces lubricant through different machines into a filter and back again. The motor was discovered in the junk pile by the engineer and had been used in a vehicle for some time. It was tested out and found to be in good order and placed on a foundation about four feet wide beneath the floor of the engine room. It is covered by a board flooring and surrounded by steam pipes, and although the temperature is never less than 100 degrees Fahrenheit, the motor has never been stopped for repairs. The only attention it receives is oiling once a week.

★

The practicability of the electrically propelled fire apparatus has been exemplified by an aerial truck which has been in service at Springfield, Mass., for a period extending over a year during which time but $3 has been spent for repairs, these consisting of a broken battery jar. The apparatus was inspected recently by an expert from New York City who instructed the department's drivers when the machine was first purchased, and who pronounced it in excellent condition.

★

An electric motor passenger service between Springfield and Boston, Mass., is being discussed and it is thought that during the summer months it would appeal to those travelling between the cities. The practicability of the plan is based upon the recent performance of two electric automobiles on a trip between New York City and Boston. The machines started from Boston and reached Worcester, a distance of 44 miles, in 1:59:00. The road between Worcester and Springfield is 54 miles with many long hills, but the electrics maintained an average speed of 21.2 miles an hour. After recharging, the vehicles ran to New Haven, Conn., a distance of 62 miles in 3:12:00, and were again recharged. The next day the automobiles ran to New York City, completing 244.8 miles in 12:24:00 actual running time and at an average of 20 miles an hour.

Electric Delivery Wagon of 600 Pounds Capacity Built by the Kentucky Wagon Manufacturing Company.

★

The Baker Motor Vehicle Company, Cleveland, O., is issuing a series of loose leaf binders giving valuable information upon the application of the electric vehicle in various commercial fields. A recent issue contained the following paragraph: "In investigating the actual cost of draft animal transportation, pains should be taken to ascertain that the accounts produced really represent the necessary expenses of service, and have not been padded by accident, the drift of tradition, or by arbitrary dissections for the convenience or economy of the auditor. A mistake would be unduly exaggerating the advantages of the machine over the horse drawn equipment."

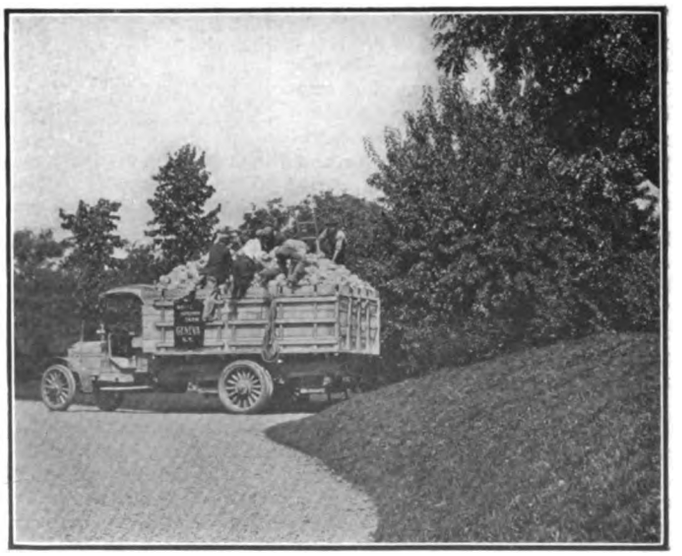
PIERCE-ARROW TRUCK ADAPTED TO FARM SERVICE.

THE utility of the power wagon in agriculture has been exploited very much in theory and it has been held that its value to the farmer is its superior speed and carrying capacity, best to be employed in the transportation of crops to market or place of shipment, and in conveying supplies. This theory is not to be denied and while this advantage as compared with animal wagons and carts is a sufficient justification for purchasing, it has been found by practical experience that a truck can be utilized for many purposes for which horses have been regarded as having their greatest usefulness.

Pierce-Arrow 66 Horsepower Touring Car Utilized for Emergency Service on Farms Near Geneva, N. Y.



It is not visionary to assume that in a comparatively brief time much of the cultivation of crops of large proportions will be by motor driven machinery. It is not seemingly practicable, however, to have diversified harvests and have special equipment for each that will require the investment of material capital. The special value of the horse in farming has been its adaptability to service where special ways do not exist, particularly in rough ground, although it has been realized that such work must necessarily be more expensive than were it haulage on roads.

The power wagon as now developed is of such construction and its power is so well utilized that it will serve any transportation purpose for which animals can be used, with entire certainty and much less expense. One of the qualities that ought to commend a motor wagon is that it has practically no expense attached to it when not in use aside from the insurance and the interest on the investment, a very large saving when it is understood farm horses are not used a considerable part of the time and rapidly eat the profits made by them while working. Were it possible to find service for the horses for all the time farming would unquestionably be more productive, yet no farmer can hire animals as he does labor, increasing or lessening his facilities at will and with a view of economizing.

It is necessary to invest capital in horses and in this respect the condition is paralleled when a power wagon is acquired, but the reduction of the expense of the unproductive period is so pronounced that there is a distinct saving even when the service appears to be comparatively small, not considering the large reserve of continued operation, for in farming service appearance is not so important a factor as in urban haulage, and theoretically and practically the vehicle ought to be useful for a considerable number of years. In other words, the truck ought to have a life by mileage and this might be made in a comparatively short time or extended over a number of years.

A very interesting experience is that of Alfred G. Lewis, whose estate, the White Springs Farm, is near Geneva, N. Y., and Mrs. George H. Lewis, whose Bellwood Farm adjoins that of Mr. Lewis. The former property is of 700 acres and the latter 350 acres, and while they are cultivated separately the owners have joint ownership of a Pierce-Arrow worm drive five-ton truck. The farms are well managed and a considerable part of either is cultivated, though sheep and cattle are largely raised and dairy products form a material share of the total. The farms are conducted to system and this requires a record of work and results as well as financial transactions. In the use of the truck it is necessary to divide its work and the cost of operation, maintenance, upkeep, repair and other expense is similarly apportioned, the tonnage being represented by a ledger account. It is not practical to have the machine do equal work for either owner and this results in a tonnage basis for accounting its service.

Mr. Lewis is an automobilist and it was the experience with a pleasure motor car that led to the adoption of the truck. The farms have horse equipment and last summer when harvesting peas from an 80-acre tract it required all the horses available to haul the vines from the field to where the peas were shelled for delivery to a canning factory at Geneva. The peas are sold shelled and after shelling it is necessary to deliver them as quickly as possible at the cannery. The custom at this farm is to carry the peas in baskets which when filled weigh 60 pounds. The need of harvesting depends upon the maturity of the peas and once the work is begun it must be hastened. Delivery after shelling is even more imperative than harvesting.

Loading Pierce-Arrow Truck with Cabbages at the White Spring Farm.

The lack of horses impelled Mr. Lewis to adapt his 66 horsepower Pierce-Arrow touring car for temporary work,

Digitized by Google

which was done by removing the body and installing a rack in which could be packed 52 baskets of peas. For 15 days the touring car was utilized to carry the crop to the cannery and when the service was accounted it was found

Five-Ton Pierce-Arrow Truck Loaded with Cabbages Ready for Trip from Farm to Market.

that the cost of haulage was decidedly reduced as compared with the use of animals. So satisfactory was the result that after consideration of the possibilities for use on the farms the five-ton truck was ordered.

The truck was delivered to the farm Sept. 1 and since that time it has been in active service with a satisfaction that has been broadened as experience has been gained. In using the machine a driver was assigned who had no knowledge of driving and it was necessary to teach him to handle it. This condition gave less actual productiveness than has been experienced since he became accustomed to his work, for the truck was not loaded to capacity until the driver was thoroughly competent.

The truck was not delivered until practically the end of the farming season which is from April to September. While all the possibilities with the machine have not been developed what has been accomplished has demonstrated that there are many uses not believed practical for power vehicles where its worth has been established.

During the three months ending Dec. 1 the truck hauled 1,316,620 pounds of freight, or 658+ tons with a mileage of 1538. The fuel burned was 376 gallons of gasoline and the cost for this was $45.12. The oil and grease used cost $6. The actual expense for operation of the machine during the period was as follows:

Driver and pay of men handling freight	$225.00
Gasoline	45.12
Oil and grease	6.00
Depreciation at 5%	40.00
Insurance	24.00
Interest at 6%	48.00
	$388.12

The average has been four miles for each gallon of gasoline consumed. The figures do not indicate the actual cost for work now performed as the expense indicated has been considerably decreased. While the depreciation is not figured high the reason is that its service is regarded as mileage, which it is expected to realize with intelligent use.

The service required of the truck is especially varied and it would appear that its uses were collectively of unusual interest. The loads have included lumber, brick, cement, sand and gravel, cherries, applies, cabbages, potatoes, wheat, cord wood, coal, bailed shavings, hay, straw, feed, milk, and sheep and cattle, in general work between the farms and the city, and about the adjacent section. In addition to this the truck has been used in plowing with extremely satisfactory results, hauling harrows over plowed land, for filling silos and cutting corn stalks as well as hauling fertilizers about the farms. The work has been widely varied and in every respect the machine has been equal to expectations.

In considering the work it is held that the truck has been equal to at least three teams of two horses for whatever purposes it has been used, has hauled freight faster and saved time when time was valuable, and has made it possible to do the farm work better and more easily. On the road between the farm and Geneva the truck has been equal to five teams of two horses and an equal number of wagons, the driver and his helper doing the work of five men. Taking the average on and off the farm Mr. Lewis estimates that the truck is more than equal in its service to three two-horse teams. In comment concerning the truck and its work, Mr. Lewis states that on these farms the truck has certainly come to stay. His conclusions, after practical experience with animals and power wagons, are worthy of careful consideration. His farm is conducted and managed as is any successful enterprise. He has decided that it good business judgment to utilize the truck for it permits of savings through economy of time, a source of profit that is always productive.

A 10-ton automobile recently has been placed in service by the Boston & Maine railroad for use of the engineering corps. The car is making a trip over the lines of the company on a regular train schedule, the driver signing the

Pierce-Arrow Truck Starting from the Farm for Geneva, N. Y., with Load of Produce.

train sheet the same as conductors. Many of these cars are in use on the western railroads, where they have demonstrated their ability to make long, quick runs at small cost.

GENERAL ELECTRIC BATTERY TRUCK CRANE.

IN THIS age of enterprise distance has been annihilated and the products of the soil and of the industrial plants are often shipped many miles to market. The expeditious and economical transportation from producer to consumer requires not only that trains and ships maintain a fast schedule, but that no avoidable delays be encountered at any point. The large quantities of freight that pass through the central distributing and shipping points can be handled so as to eliminate delay only through the utilization of very efficient devices. Marvellous reductions in the time consumed in handling free flowing bulk freight have been made during the past few years, through the use of the belt conveyer, elevator, grab bucket, ore bridge, etc.

In the matter of package freight, the motor truck has demonstrated great superiority over the horse drawn vehicle. Where a fleet of commercial motor wagons is maintained to transport heavy packages to storehouses, shipping points, or other places, expedition in loading and unloading becomes imperative. Various methods for accomplishing this are now employed, and among these may be mentioned the battery truck crane. This enjoys three notable advantages, in that it always is set up ready for instant use, can ordinary intelligence can become fairly proficient in its operation in a day and expert in a few weeks.

Where the material to be loaded is in parcels of one ton or less and is in a pile where the truck can be brought alongside, the battery crane is placed in an advantageous position, the brakes set, and the vehicle remains stationary as the boom moves back and forth between the picking up and depositing points. Some idea of the rapidity with which this device works may be gained from the following performances:

Three hundred castings aggregating 65,000 pounds were unloaded from a gondola car in five hours, giving an average of 1.2 lifts a minute. A box car was loaded with 64 800-pound barrels of plumbago in 25 minutes and four cars in 2.5 hours, the latter work including spotting the cars. This averages two barrels a minute hoisted nearly five feet and swung well inside the car.

The short wheelbase permits short turns, so this machine readily may be driven about shop aisles, congested piers, among piles of material in the storage yard, and may even be carried up elevators to get goods which are to be loaded on motor trucks. By this pick-up-and-run meth-

General Electric Company's Battery Truck Crane Loading Truck with Material Collected from Various Points.

move quickly from place to place, and carries its power plant with it as a permanent part of its equipment.

An accompanying illustration presents the crane recently brought out by the General Electric Company, Schenectady, N. Y. This device is an electric vehicle which has a crane arranged to swing in an arc of 180 degrees mounted on the front end. The hook is raised and lowered by a one-ton hoist, located immediately behind the crane, and the motors driving this and the vehicle are operated from a storage battery, so situated at the rear end as to act as a counterweight. Special attachments are fitted to suit the character of the work contemplated, these consisting of rope and chain slings, barrel tongs, bale grapples, box hooks, snatch blocks, small tools, etc.

The electric hoist comprises a compact weather proof motor, a controller, gears, and a drum combined in a unit, capable of lifting one ton, 20 feet a minute. The hoist controller handle is connected to a lever convenient to operator, who pulls to raise, pushes to lower, and lets go to stop the load at any point, the lever going to the "off" position in the latter instance and holding brakes automatically locking the drum. A load brake also is provided to prevent excessive speeds when lowering. The simplicity of the operating mechanism is held to eliminate the need for technically trained men, it being claimed that a man of od, in which the material is carried on the hook, 60 800-pound barrels of plumbago were moved 300 feet in one hour, only one helper being required. One hundred and fifty 300-pound boxes of rubber were conveyed 75 feet and loaded into a box car in 50 minutes, three boxes being slung together and a round trip made every minute.

The crane can be coupled to trailers and accompany the fleet of trucks for the purpose of unloading them when the material is being conveyed to some central point. It also serves as a general utility vehicle, quickly replacing spilled loads, pulling the trucks out of the mud, and transferring packages from disabled apparatus where delays would occur otherwise.

FEDERAL TRUCK USES GOODYEARS.

The Federal motor truck, made by the Federal Motor Truck Company, Detroit, which won the cup in the recent Chicago-Detroit reliability contest and has been demonstrating in that vicinity since, with the exception of the time it was employed as a baggage car on the Glidden tour, is shod with Goodyear tires, made by the Goodyear Tire & Rubber Company, Akron, O. Despite the poor roads encountered on its southern trip, the vehicle went through without the loss of a moment's time through tire trouble.

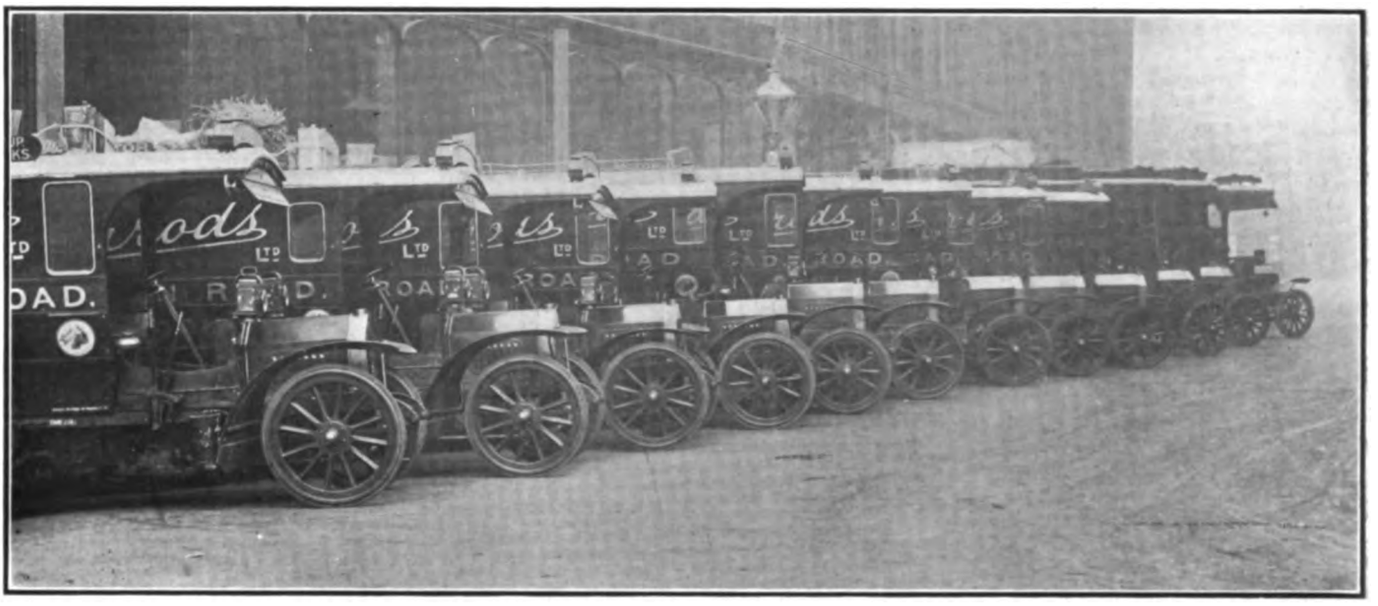
SIX YEARS IN DEPARTMENT STORE SERVICE.

Figures Presented by British Installation of 56 Motor Vans Indicates Enormous Saving Over Utilization of Horses with Increased Business Development of 100 Per Cent.

By C. A. French.

WHILE many department stores in the larger cities of this country have installed extensive fleets of mechanical transports, it is rare indeed that any is found which has been in service for a period of several years. For this reason, it undoubtedly will prove of interest to consider the work performed by a foreign installation, which covers a little more than six years. The figures presented herewith were compiled by Leycester Barwell, one of the partners in the firm of Shoolbred & Co., London, Eng., which began replacing its horse equipment with Lacre trucks, made by the Lacre Motor Car Company, Ltd., Letchworth, Eng., in October, 1905.



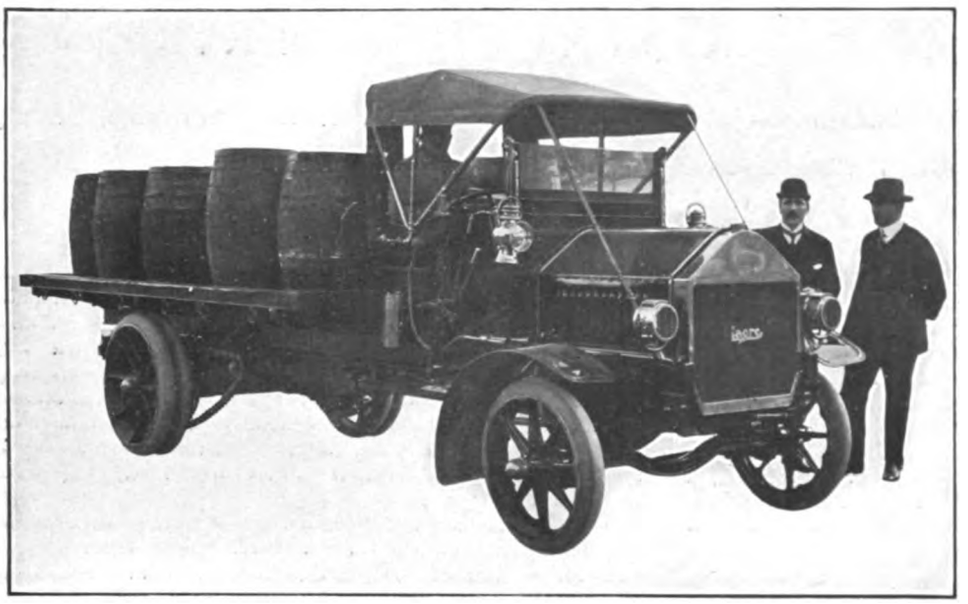
In order to become familiar with the construction of these cars it will be necessary to consider their details, information for which has been furnished by one of the officials of the Lacre Motor Car Company. He writes as follows:

"Our chassis comprise a range of models having a net carrying capacity of 10 cwts. to five tons, 12 to 50 horsepower, and two and four-cylinder motors. (It is well to remember in this connection that an English cwt. is 112 pounds.) In their design simplicity has been studied especially with a view to the vehicles being handled by unskilled drivers. No startling innovations have been embodied; the chassis are designed on proved lines throughout. With our special experience and facilities the production of entirely new designs, as these are for the latest type Lacres, has enabled us to include in our vehicles only the latest and most approved practise.

"We claim that we have embodied all that is best in the designs of other manufacturers, combined with features which are unique. The large number of repeat orders with which we have been favored, we think is sufficient proof our machines are considered most desirable by those best fitted to judge.

"We have made a very special feature of the ease of repair, recognizing that a great deal of time is lost in overhauling vehicles, when by methods such as we have adopted, one unit which requires repair may be substituted by another, and the cars can thus be kept on the road while defective parts are being remedied. For example: The entire motor unit mounted on a sub-frame can be detached from the main frame easily and quickly, and a complete spare engine substituted, so that the necessary work may be accomplished without keeping the vehicle off the road for any appreciable time. For a fleet of cars we recommend keeping as stock, one complete spare unit, and thus overhauls to the motor can be going on at the time most convenient to the user, without interfering in any way with the service.

"We ourselves have designed our engines throughout, and they have cylinders cast in pairs. The 12 horsepower two-cylinder and the 30 horsepower four-cylinder have a bore of 4.33 inches and stroke of five inches. The 18 and 35 horsepower motors have bore of 4.875 and stroke of five inches. Revolutions are limited to a maximum by a heavy type centrifugal governor situated in the crankcase. The lower portion of this case is merely a sump for oil, and contains a patent oil pump, the whole being removable without disturbing the main bearing of the engine, and this latter may be attended to without removing the motor from the chassis if deemed advisable.



Shoolbred & Co., London, England, Have Been Operating a Fleet of These Lacre Vehicles for Over Six Years with Splendid Success.

"The lubrication is forced to the main engine bearings and connecting rod big ends, and a simple and effective telltale fitted on the dashboard shows that the lubricator is performing its work satisfactorily. The patent oil pump is valveless and barring breakage, it is impossible for it to fail. It is driven direct from the exhaust camshaft, and requires no adjustment of any kind. The crankshaft is of special high grade steel, and the camshafts and wristpins are case hardened; the camshafts and cams are cut from the solid.

"The inlet and exhaust valves are located on opposite sides of the engine and are mechanically operated. They are interchangeable in all sizes. The valves are made of nickel steel and are of specially large dimensions.

"The ignition which we have adopted is fixed Bosch high-tension magneto. An advance can be arranged for it if required, but we do not recommend it. Provision is made

Digitized by Google

Platform Type Lacre Truck, Large Orders for Which Have Been Filled in Australia.

on the engine for fitting a duplicate magneto, this comprising magneto, cables, plugs, etc. We particularly recommend this for export purposes. We can fit, if desired, a high-tension coil, storage batteries and plugs as an alternative, or additional, to the spare magneto, but we recommend the fitting of the latter.

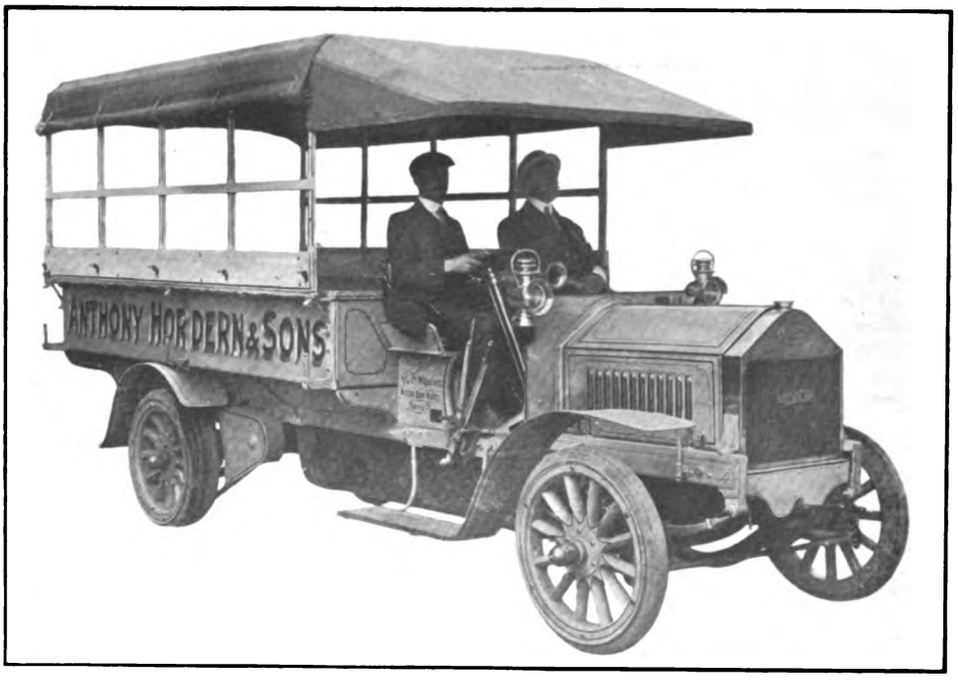
"Cooling of the engine is effected by a large centrifugal pump driven direct, and a radiator of large capacity. The water is circulated through vertical gilled tubes, and the fan situated behind the radiator is belt driven; the tension of the fan belt is adjusted easily.

"The simple clutch is leather faced, conical, engaging with the flywheel. The drive to the gearbox is transmitted through a special form of enclosed spring drive, which is particularly efficient. The gearbox is provided with four speeds forward and reverse in the three, four and five-ton sizes; three speeds forward and reverse in the lighter vehicles. All speeds engage by means of dog clutches, except the first and reverse. The change speed mechanism is of the gate type.

"Final transmission from the gearbox is through the differential gear contained in the box which is a part of the same casting, and thence by cross shafts and side chains to the rear hubs. The differential mechanism on all models includes two crown wheels. This is an expensive feature.

"Special attention has been given to the efficiency of the brakes, those worked by foot operating on a single drum fitted on the substantial extension of the differential shaft, and those by hand being internal expanding forms operating on the rear hubs. The shoes have detachable cast iron slippers which can be removed readily and renewed cheaply, when worn. The hand brakes are compensated, of course, and both have very accessible hand adjusting screws.

"All chassis are constructed with a particularly large wheel lock. This is a very special feature of our vehicles, and they can be turned in a remarkably small circle. All models are well protected from mud by a metal shield suspended under the chassis and readily detachable."



The Lacre chassis are fitted with a variety of bodies, as indicated in a measure by the illustrations herewith. An order for 10 five-ton platform trucks, similar to that shown, followed a single trial in Sydney, Australia, and four of the 30 horsepower two-ton hinged sided wagons have been shipped to the Bangkok Corporation in Siam. Numerous repeat orders are recorded both at home and abroad.

The Shoolbred installation is now one of the largest fleets of motor transports operated by a single firm in Great Britain, and the knowledge of commercial motor traction gained from it undoubtedly is the best that can be obtained. Two cars were purchased in 1905 and the present equipment totals 56, all of the Lacre make. Most of these are of the 10-cwt. capacity, although the eight purchased this year were of the 18 horsepower 25-cwt. type. In a letter to the writer, Mr. Barwell says:

"We have 56 motor vans on the road at present, all supplied by the Lacre Motor Car Company. The first two were put on the road Oct. 2 and 9, 1905, and have done more than six years' work. We estimate that each of these two vans has covered 100,000 miles on the road. From their present condition, they should run at least another 50,000 miles, and we may count on a life of eight years a van in estimating depreciation. When the time comes to scrap the old models, they will be replaced by latest type Lacres from the Letchworth factory.

"By the aid of mileage recorders we find that each van runs about 18,000 miles a year, making an average of 63 miles a day on the road. Some vans do much less, but many do more, a few rounds running into 25,000 miles a year. Our longest regular service is to Hindhead and Haslemere three days a week. This route averages 120 miles a day.

"It is interesting to see how such a service as this grows. We started by delivering a vanload to a certain house some miles south of Haslemere, whenever the order was large enough to enable us to do it by road. We then

Collapsible Top Vehicle Produced by Lacre Motor Car Company, Sold in Increasing Numbers.

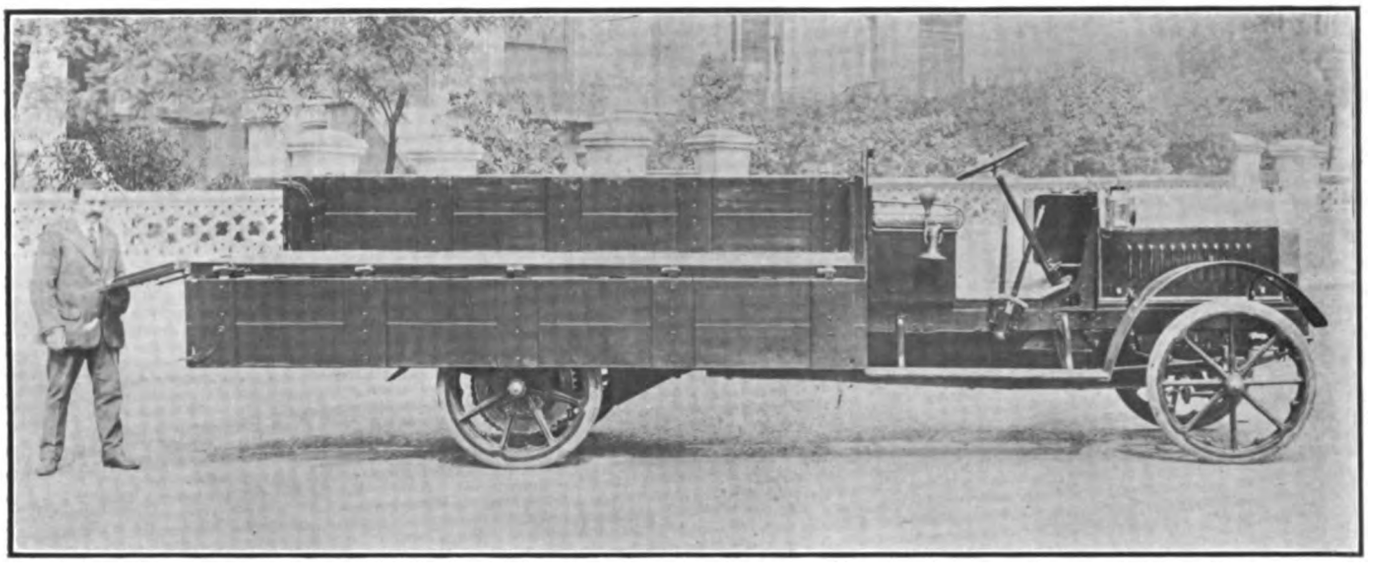
Digitized by Google

arranged a monthly service to this one house. By degrees a few others came to know this, and the service became fortnightly, then weekly, until finding that the weekly service often meant sending two vans on one day, we made it three days a week as at present. In the same way our service to Hitchin, Letchworth, Baldock, etc., began monthly, and also is now three days a week.

"Before we started motor vans we had 300 horses in our stables, and at present we have 120, mostly for heavy work. Each van does the work of at least six horses on an average, and many rounds would take quite eight horses; that is, supposing it were possible to use animals at all. This cannot be done, however, as vans do not start until fresh supplies are in from Covent Garden Market, and the fish market, and the day would not be long enough to deliver fresh fruit, vegetables, fish, etc., in time to be of use. By means of these 56 vans, we have doubled our road mileage a year, as we have added many new rounds that could not be undertaken with horses. On the supposition that all our present routes could be covered with horses and give satisfaction, we estimate that we would require from 500 to 600 horses in our stables.

"But if we had 300 horses six years ago and now do the work of from 500 to 600, and in the meantime have doubled our road mileage a year, what about the extra expense? Taking the average of the last six years we have

Average Cost of Tires.



48 vans, first year	$173.12
41 vans, second year	226.08
31 vans, third year	213.37
20 vans, fourth year	251.97
6 vans, fifth year	263.80

Average Cost of Repairs.

48 vans, first year	$142.83
41 vans, second year	271.09
31 vans, third year	235.83
20 vans, fourth year	264.57
6 vans, fifth year	239.77

This gives an average expense of $211.07 for tires and $219.30 for repairs on each vehicle. Mr. Barwell disregards the first year's costs as being too favorable, bringing his average to £47 a year for tires and £53 for repairs. His table of costs follows:

Depreciation, 12.5%	$243.32
Repairs	257.92
Tires	228.73
Fuel, 1645 gallons @ 14.2 cents	233.59
Driver @ $7.53 a week	392.24
Oils, grease, carbide, etc.	34.06
Washing	29.20
Insurance, third party only	26.28
Total	$1445.34

One of the Four Two-Ton Hinge Sided Trucks Recently Shipped by the Lacre Motor Car Company to the Bangkok Corporation in Siam.

increased our stable expense £400 ($1948.60) a year, and to offset that we have increased our road mileage no less than 100 per cent.

"In the six years, besides extending all our existing country rounds, we have added 20 districts by the use of 12 additional vans; four vans do a district daily, and eight do one district three days a week and another the other three days. These 12 vans mean 12 drivers at 30s ($7.30) a week and 12 porters (helpers) at 26s ($6.32), or increased wages of £1740 ($8456.40) a year. But as motor vans are so much cheaper to run, the total expenses only average £405 ($1968.36) a year more. Had we put on 12 additional horse vans, each worked by four horses, the expense must have been increased £5000 ($28,300) a year, including the wages of 12 porters.

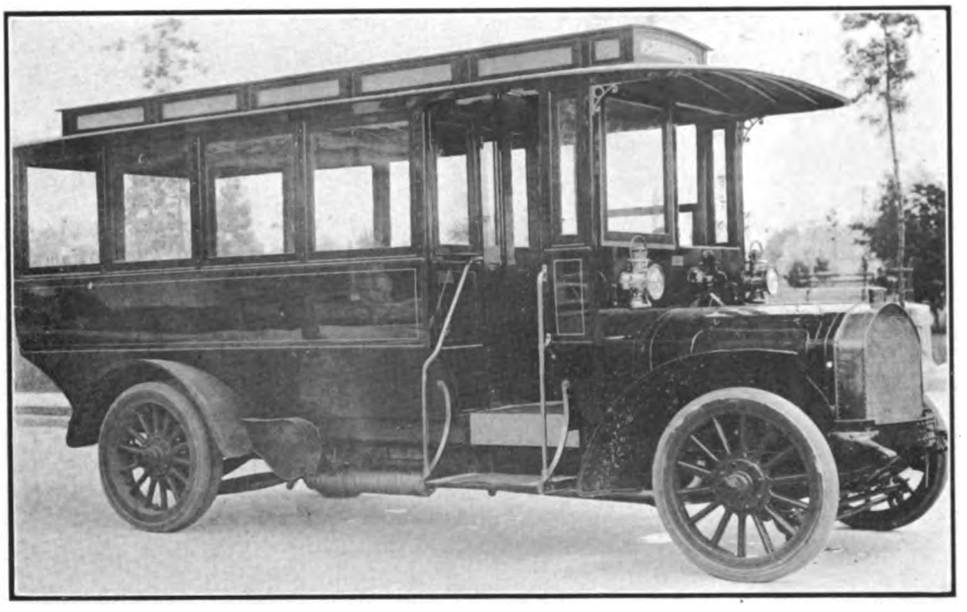
"Our country rounds, when done with horses, averaged 45 miles a day, and each round took four horses to work, two working and two resting. Allowing 18 days off in the year for repairs to van and absence of horses from lameness, colds, etc., not to mention their deaths, such a round would total about 13,000 miles a year, and at the lowest would cost £350 ($1701) to work. This is at the rate of 6.5d (13 cents) a mile. From the accompanying figures it will be seen that a country round of 18,000 miles a year cost £300 ($1458), which is at the rate of four pence (eight cents) a mile. Porters' wages are not reckoned in either case."

Mr. Barwell's figures have been converted into American money for the better understanding by the reader, and cover one year's service.

He adds: "I have not allowed for interest on capital or garage rent, but I have not taken either item in my horse expenses. All our buildings being freehold, it is difficult to estimate the rent. If the interest come out more for motor vans, the rent certainly would be lower, as one motor van requires much less room than one van and six horses. Engineers' salaries are charged in 'repairs for motor vans.' As I was responsible for the stables for 12 years before we started motor vans, I was not likely to be prejudiced in favor of the new locomotion, and in the figures given, all taken from our books, I have been careful not to favor the motors.

"We have done the whole of our repairs for 4.5 years, and the only men engaged on account of the new traction were mechanics in the repair shop. Not one single man has been engaged as motor driver, and our engineer and his assistant have been with us for several years in our electrical engineering department. Of the last two it is difficult for me to speak except in the superlatives of praise, and I always shall feel in their debt for the keenness they have displayed in making our motor fleet a success."

To return to Mr. Barwell's figures: His depreciation would indicate that each truck costs practically $2000. The



Digitized by Google

item of repairs undoubtedly is governed somewhat by the cost of labor, which is decidedly different from in America, as evidenced by the wages paid driver and helper. Just how this same ratio is maintained with respect to mechanics is a point that is not made clear in Mr. Barwell's letter. Tires were solid, and the price probably does not differ greatly from those in use here, judging from the cost of the truck.

Gasoline is measured in England by the imperial gallon, which is equal to 1.20032 gallons in America. That means that the average fuel consumption was 1270 gallons, which could be bought in this country for at least 10 cents, making the cost $127, as against $233.59. The charge for oil, etc., appears to be about the same as would be the case in America.

Mr. Barwell explains that all the company's buildings are "freehold," which means that they are owned outright by the firm, instead of being leased for a term of 999 years as is quite common in that country. Even under similar circumstances it would be customary to charge something for rent in America.

The chief value in Mr. Barwell's figures lies in the statement that the added stable expense has been but $1950 to to secure an increase in business of 100 per cent., while it would have taken an increase of some $19,800, disregarding the wages of the 12 helpers, which were needed in either case, to have accomplished the same result with horses, granting it would have been possible to do the work with animals.

Mack Enclosed Passenger Omnibus Providing Seating Capacity for 18 Persons.

MACK ENCLOSED PASSENGER 'BUS.

Motor propelled omnibuses have been in service abroad for several years and they are now being introduced in this country. Chicago has taken up this form of service which example is being followed by Indianapolis, Ind., and in the accompanying illustration is shown a type of vehicle adapted to this kind of work. The machine is made by the Mack Bros. Motor Car Company, Allentown, Penn., a constituent of the International Motor Company, New York City.

Entrance to the automobile is at the front and the body dimensions with the overhang provide seating capacity for 18 persons. Energy is furnished by a four-cycle, four-cylinder, water-cooled motor of four-inch bore and five-inch stroke, rated at 48 horsepower. Dual ignition is provided and lubrication is by a mechanical force feed oiler, also a splash system in the crankcase. A friction clutch of the cone type transmits power through the gearset which is the selective individual clutch method, to the countershaft and thence to the rear wheels by side chains.

Semi-elliptic springs are utilized in front and full platform in the rear. Solid tires are fitted to the wheels, the front members being 36 by five inches and the rear 36 by 3.5, dual. The wheelbase is 13 feet, two inches and tread 68 inches. The approximate weight is 6800 pounds.

DELIVER WHEELS BY VELIE TRUCK.

Franch & Hecht, Davenport, Ia., maker of steel wheels, has purchased a three-ton Velie truck, made by the Velie Motor Vehicle Company, Moline, Ill. The car is to be tried out on the delivery routes for which between 15 and 25 horses are now employed. If the plan works out as expected all the horse drawn equipment will be replaced with Velie trucks.

LONG PLEASURE TRIP IN REO TRUCK.

Mr. and Mrs. Ralph Barker of Empire, Ore., recently completed a most novel transcontinental trip, utilizing a Reo light delivery wagon, made by the Reo Motor Car Company, Lansing, Mich. The journey occupied 43 days, and when the truck arrived at its new home in Oregon it apparently was in as good condition as when it left Stratham, N. H., where it was purchased.

A few months ago Mr. and Mrs. Barker left their homestead in Empire on a visit to their native town in New England. While there, they purchased the automobile, and decided to return over the road. A touring cover was attached to the vehicle, converting the interior into a regular living room, and the further equipment included a complete camping outfit.

The idea was to provide as much enjoyment as could be gained in a tour of this nature, and Mrs. Barker has informed R. M. Owen & Co., New York City, distributor for Reo cars and trucks, that the trip was one continuous round of pleasure. The route included Chicago, Council Bluffs, Omaha, Cheyenne, Boise, to Burns, Ore., thence over the Prineville-Santiam route through the Willamette valley to Roseburg and across the Coast range to Empire.

The total distance was not far from 7000 miles. Although much rain and muddy roads were encountered in Nebraska, Wyoming, Idaho and Oregon, the party reached home nearly two weeks earlier than it had expected. Not a cent was paid for railroad fare, the entire journey being made in the motor truck.

GARFORDS IN TWENTY CAR LOTS.

That the business world is beginning to realize the many possibilities of the commercial vehicle in transportation service, appears to be borne out by numerous recent sales of cars in large lots. The R & L Company, New York City, reports a contract with James Butler, a grocer who operates a chain of stores in the metropolis, for 20 one-ton Garford cars, made by the Garford Company, Elyria, O.

WATERBURY HAS CORBIN AMBULANCE.

The Waterbury Hospital in Waterbury, Conn., has purchased a motor ambulance made by the Corbin Motor Vehicle Corporation, New Britain, Conn., and thus becomes one of the few hospitals in that state to be thus equipped. The new machine will have two compartments so that several patients may be carried at the same time.

HAULING AND DISTRIBUTING ICE BY POWER WAGON.

Economy and Reserve Facilities Experienced with Truck and Delivery Supplementing Animal Service Under Conditions Extremely Variable---Results Decidedly Satisfactory in Outside Work---Great Saving When Vehicles Are Not Active.

By William W. Scott.

THE haulage and distribution of ice, either by animal or motor power, is varied greatly by changes of temperature and by seasons. Obviously at two periods of the year there are large and exacting demands for the use of animals. With power wagons the winter requirements do not parallel those made upon horses for it is not possible to utilize them in the harvesting of ice.

In considering this subject with reference to mechanical transports it is well to understand the conditions obtaining that the economic possibilities may be made clear. There is a certain constant volume of the business of an ice dealer, that is, so far as service is required, but this is varied by the weather. There is another proportion that demands attention for periods differing in length, beginning with late winter or early spring and continuing until well into the autumn or early winter.

Peerless Truck of Four Tons Capacity in the Service of the Pocasset Ice Company, Providence, R. I., Equipped with Special Body.

The ice is harvested as quickly as is possible, although the actual work may be at intervals more or less frequent for several months. In preparation for ice harvesting there is preliminary work done at convenience. Occasionally it is necessary to transport equipment or supplies from the one locality or another, when expedition may be of extreme importance. In the actual cutting of ice the plows are drawn by horses for which work the power wagon cannot be used, though it might be made a substitute for animals used for hoisting. Quite frequently the places of harvesting are long distance apart and if conditions necessitate the work being done simultaneously the total number of animals required might for a brief time be practically all that are owned by the ice cutter. As quick action is advisable when a harvest is begun a dealer must have facilities that are at his command when needed. For harvesting some horses must be used unless means are materially changed.

The distribution continued through the winter months is increased as the weather becomes warmer until it is at its height during the summer, and then there is gradual diminution of volume until it is lowest with the coldest temperatures. Ice is a perishable commodity. It is estimated that the shrinkage, a loss borne entirely by the dealer, from time of cutting to delivery, will average 50 per cent. Of this approximately 33 per cent. is in the ice house and the remainder is breakage and meltage. When exposed to the air the loss is very rapid and the warmer the atmosphere the greater the shrinkage. Rapidity in handling is a decided economy but the character of the loads have necessitated heavy carts and the slowest of haulage. Loading and unloading cannot be greatly expedited, and as there is but little difference in speed of draft animals when hauling loaded or empty carts endeavor has been toward minimizing the service of the delivery wagons by carrying to them whatever replenishments were necessary, so that delivery may be made with the least actual loss of time by the drivers and helpers. This applies to the usual house to house delivery, or retail trade.

The wholesale delivery is in quantities from several cakes to several tons, and obviously the number of calls for a team is much smaller. The haulage is not as long as a rule and the direct loss by shrinkage is less than with the the family service. Often in some localities the available ice supply is exhausted and this necessitates buying ice or shipping it from another place. The ice is hauled in cars and it must necessarily be handled quickly to minimize shrinkage. Generally ice so received would be delivered from the car.

It will be seen that the distribution of ice may require many stops close together (taking much time to cover a short distance), frequent stops in different sections of a community, stops at varying distances apart, or, with the wholesale branch, delivery by the load or in quantities requiring a few calls, such distribution generally being scat-

Digitized by Google

tered. Of course it is impossible to concentrate delivery, but it is often necessary to confine it to sections where the number of customers make it profitable to call.

With rare exceptions all ice dealers of importance believe it necessary to maintain an equipment sufficiently large to meet with the greatest demand upon them. To insure continuance of custom it is desirable to serve all reasonable demands, and excess patronage must be cared for so far as possible. There are limitations to service, however, particularly when extremely warm weather will double, triple and sometimes quadruple the delivery service. When other business men feel that it is necessary to reduce the work of their animals the ice dealers often are required to work theirs beyond normal requirements, even at the risk of incapacitating or perhaps permanently reducing their serviceability. There is a limit to the work of the men as well.

The experience of the Pocasset Ice Company, Providence, R. I., the past season with power wagons supplementing its animal service has established the efficiency of the former for a certain work. This is resulting from the use of a Peerless four-ton truck and a Reo 1500-pound wagon. It is not to be assumed that this experiment was undertaken without uncertainty as to results. The extreme heat demanded a service beyond the resources of the concern, and a couple of demonstrations by the Reo agent resulted in an order and the use of the demonstrated wagon until the

Peerless Truck in Contract Outside Service, Plied High with Bundled Laths.

machine ordered had arrived. A demonstration was made for two days with the Peerless truck, which was purchased upon condition of immediate delivery, although this deprived the agency of the only truck it had, and it has since been without a demonstrator.

Most large ice companies have central supply stations where ice is received from outside sources, from which the distribution is made by carts which renew supplies at this point. From these stations supplies are also sent to smaller stations in different sections where other series of carts are loaded, this saving the time of the drivers, animals and carts in loading and hauling. These stations are also supplied from the ice houses contiguous to the city or town. Where such stations are not used it is customary to send supply wagons from the ice houses or the freight yards to different localities to meet the peddling carts.

Where a supply wagon is used the driver will go to the vicinity where he ought to meet a peddling cart and hunt until its driver is found. Then the peddling cart is driven to the supply wagon and the ice transferred. The process is repeated until the supply wagon is emptied, when it returns for a fresh load. Naturally in such service saving of time means less loss in the services of the carts, animals, the drivers and the shrinkage of the ice, which is an important factor, for all loss must be borne by the dealer.

In the rapidity of supply service there is decided economy. The loaded carts are sent out as early as delivery can be begun, this varying with reference to family or business trade. According to conditions one, two or even three men may attend each cart. With the wholesale trade at least two men work on a cart because of the labor necessitated in handling the cakes. The carts having regular route work are drawn by a pair of horses and start with loads of about 6000 pounds each. The daily travel is about 18 miles, but Saturdays and holidays the work is increased as approximately 50 per cent. more ice is supplied.

The family delivery is usually solicited by the drivers. In the winter one route may be a combination of the customers remaining from several summer routes, but in the spring the drivers call on former customers and by distributing cards and others means of advertising develop business. The delivery is extended so far as each man can attend to it, and then he is given one and sometimes two helpers, as may be necessary. A route may be extended over a considerable area.

Where the customers are close together the horses become trained and some will work with much intelligence, stopping at customers' houses and starting with the sound of a gate closing or the driver's steps, so that unless there is 100 yards or more to drive the animals often follow along at or without command. In work of this character, where it would be necessary to stop and start a motor to prevent possibility of accident, and where the rapidity of the driver's movement largely governs service, a power wagon would not much expedite delivery, even with a helper to drive it. It would, however, have an advantage in going to and from the locality of delivery.

The Peerless truck was placed in service delivering ice from the ice houses to route wagons and in this work it was found to have a decided advantage. The average trip is estimated at six miles, and eight loads of four tons each were delivered as occasion required, this being about the maximum. The time required for loading depends on conditions at the ice houses and the unloading upon the needs of the carts supplied. The truck replaced three supply wagons, the driver and helper of the truck doing the work of three drivers. In the work required by the company there was and now is considerable variance, because when not actually needed and outside orders were received the truck was often devoted to other work for varying lengths of time. It was not used exclusively for wholesale delivery, but its work was such as to justify the belief that with three men the truck could do as much as four horses and four men. Besides this in the event of emergency orders the truck can be loaded with any quantity of ice within its capacity and hustled along. This enables the acceptance of orders that could not otherwise be taken, and extends the radius of the business.

The active head of the concern, Clinton A. Walch, has owned automobiles for nearly 10 years and this experience has been of material benefit in directing the use of the truck. The driver had no experience until he was set at work under the observation of a demonstrator, and he has been trained to meet Mr. Walch's requirements. He is required to give whatever attention is essential to operation, but when work is beyond his capacity mechanics employed by the company assume it. In operation Mr. Walch insists upon cleanliness of the mechanism and the truck is washed each night. The mechanical attention thus far needed has been practically adjustment instead of repair. The tire wear has been comparatively small. It will be seen that so far as actual expense for maintenance and tire renewal is concerned the truck has not been used a sufficient length of time to give figures of real value.

The truck has a maximum speed of 13 miles an hour, the governor not allowing excess of this no matter what the position of the throttle or ignition levers. When the truck was first bought a broken governor spring reduced the speed to about eight miles an hour, and Mr. Walch decided not to make replacement of the spring until the crew was familiar with the machine. This also brought the gasoline consumption down to approximately three miles to the gallon, which was understood and not objected to. The gasoline consumption is normally about six miles to the gallon and about 100 miles is driven to the gallon of oil.

Digitized by Google

Basing estimate on daily service for a variable period is unsatisfactory and to make estimate on both variable service and variable periods would appear to be sheer nonsense, but there are the best of reasons for making conclusions which will appear.

The Pocasset Ice Company ordinarily has in service about 50 horses, which number is increased by purchasing or hiring as occasion may demand. The experience has always been that in the time of year when the delivery was greatest the facilities were never adequate, and yet when the service diminished and there was excess the value of animals trained to the work was such that only those that had ceased to be useful were disposed of. This has meant finding work for the horses, which must be exercised when not working, a problem with which every ice dealer has to deal. It must be apparent that taking the delivery outfit of a business of this character, with the service increasing and diminishing very much, what would be necessary not more than six months of the year must be carried the remainder at no profit, if not at actual loss. This means that all kinds of haulage work is undertaken, casual and regular, and with the time lost there is usually no expectation of anything more than keeping the service intact at minimized expense. This condition has established a price which ranges from $4.50 to $5 a day for the service of a pair of horses, cart and driver for regular service, and naturally something more than this when the work is temporary or for a short period. There are times, however, when service is sought that commands higher prices. With horses the natural limitations of the animals minimizes work that would naturally be the most productive.

With this company it has been found possible to undertake haulage that horses could not do, and these long hauls have often been so arranged that both trips have been productive. This has resulted in the truck being sent for runs of more than 100 miles in a day. One of these was from the garage to Greenville, R. I., where a load of four tons of fancy apples was taken on and carried to a horticultural exhibition at Boston. Another was a delivery for a furniture dealer during which, with a late start and numerous waits, the machine made 70 miles. Another work was carting an apple harvest to a cold storage plant, yet another was hauling lumber, still another hauling grain, and so on, it being impossible to account for this as regular service and compare it with horse work. While this cannot be tabulated for comparison its value is understood and established with the company.

In this connection the work of the Reo power wagon may be emphasized. While it was used for a few days to supply ice to the peddling carts it has been generally sent out with special orders, ranging from a few deliveries for regular customers who had been "skipped" by the drivers or helpers to a single load demanded in an emergency call. It has been particularly useful during periods when all the service was worked to the limit, and has carried as many as 13 full loads varying distances in a day. During the shipment of ice from storage at Oxford, Mass., the wagon was sent over the road from Providence to that town and was there for about two weeks carting ice from the houses to cars, doing the work of two single-horse carts, to say nothing of saving in shrinkage by its superior speed and the fact that one man did the work of two drivers. While the record kept shows the weights carried by this machine in delivery work no mileage or fuel, or lubricant data has been preserved. Here again the broad statement of the company as to the utility of the machine is the best that can be given. This is in effect that the Reo has been all that was expected and has been entirely satisfactory. The speed of this machine has offset its limited capacity for ice delivery.

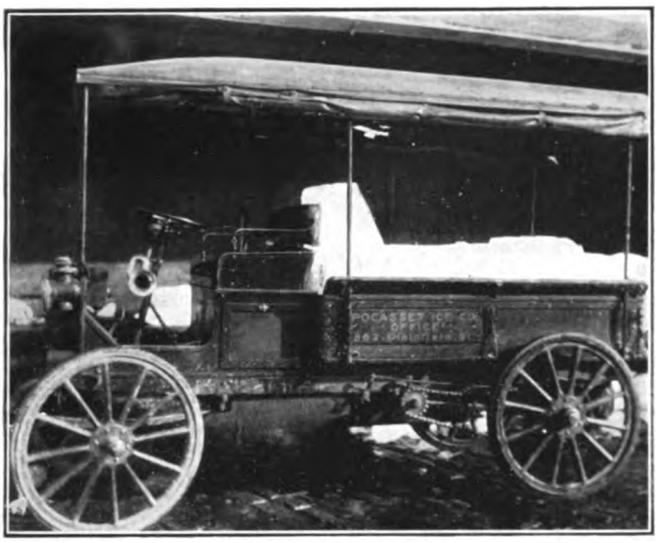
It is apparent that service must be estimated on comparisons with vehicles of corresponding capacities and that manifestly it is impossible to utilize one type, for instance, with equal satisfaction for every requirement.

Relative to the work of the truck the following data demonstrates what it accomplished in regular service, this covering a period of two weeks and showing the mileage and consumption of gasoline, it being loaded with from 3000 to 8600 pounds of ice:

Date	Mileage	Total	Gasoline Gals.	Total
October 9	40.8			
October 10	20.6		5	
October 11	52		12	
October 12	46		9	
October 13	46		7	
October 14	40		8	
		245.4	—	41
October 16	44.4		8	
October 17	48			
October 18	37		8	
October 19	37		8	
October 20	36.8		7	
October 21	37.9		8	
		241.1	—	39
		486.5		80

This shows an average of 40.5 miles daily and an average of 6.08 miles to the gallon of gasoline consumed. It should be said that this does not represent the maximum of truck service, but what was necessary during the period given.

The truck as a supply delivery has taken the place of three two-horse carts, and its crew of two the place of three drivers. Making comparison of the cost of the truck and horse outfits we find the following:



Horse Outfit—			
6 horses at $350 each	$2100.00		
3 carts at $250 each	750.00		
3 sets harness at $75 each	225.00		
Incidentals	100.00		
			$3175.00
Truck Outfit—			
Chassis	$3700.00		
Body	200.00		
Incidentals	100.00		
			$4000.00
Operating Expense, one year—			
Horses:			
Interest, 4%	$ 127.00	$ 127.00	
Depreciation, 10% annually, horses	210.00		
Depreciation, 10% annually, carts	75.00		
Depreciation, 20% annually, harness	45.00		
		$ 330.00	
Care and Maintenance—			
6 horses at $1 a day	$2190.00		
3 carts at 50c a day	547.50		
		$2737.50	
Supplies	$ 100.00	$ 100.00	
Attendance—			
3 drivers at $12 a week each	$1872.00	$1872.00	
			$5166.50
Truck:			
Interest, 4%	$ 160.00		
Depreciation, 20% annually	800.00		
Insurance	180.00		
		$1140.00	
Care and Maintenance—			
Tires	$ 900.00		
Repairs	400.00		
Gasoline	240.00		
Oil	48.00		
Grease	20.00		
Supplies	100.00		
		$1708.00	
Attendance—			
Driver, at $15 a week	$ 780.00		
Helper, at $9 a week	468.00		
		$1248.00	
			$4096.00
Difference in favor of the truck			$1070.50

It will be noted that the truck is depreciated at 20 per cent. annually, and that half the depreciation is allowed for repair, making the cost annually for maintenance $1200. To this should be added the tire expense. The tires are 36 by five inches on the front wheels and 40 by five inches dual on the rear, these being guaranteed for 8000 miles by the maker. The mileage of the truck is estimated at 250 weekly, or 13,000 annually. This would allow a total of 65,000 miles for the period of five years that has been the basis of estimate, and this is nearly 100 per cent. less than is regarded as a reasonable mileage. In fact, this is but a third of the mileage that is placed as the life of a first class machine by European builders.

Should there be mileage in excess of 65,000 this would be clear gain and all in favor of the truck, while it would be against the horse outfit. Of course there should also be considered the reserve possibilities, in which the truck has

Digitized by Google

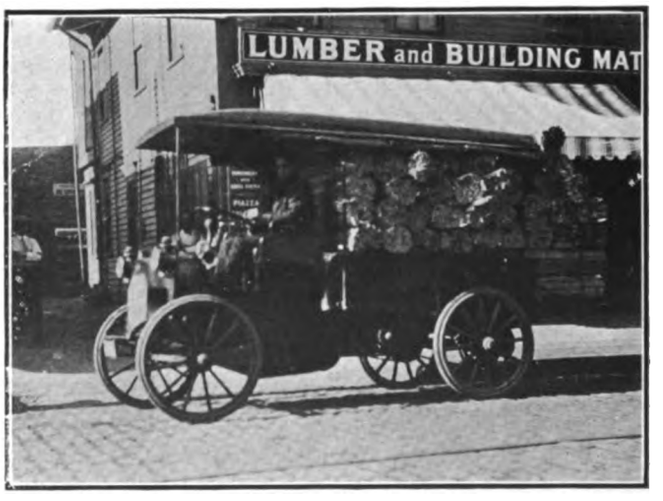
double capacity with an additional crew, and its greater utility during periods of extreme need. The cost would be no greater for any item save fuel, lubricants, tires, repairs, and attendance. Additional horse service could only be ob-

Reo Power Wagon Used for Emergency Delivery by the Pocasset Ice Company.

tained by buying or hiring extra animals at the prevailing market price, and the drivers and animals would not be trained to the work and consequently would not be as productive.

The body equipment of the Peerless truck has been placed at perhaps a less price than might be paid for a similar construction, for this was built by the ice company in its own shop and from selected material to meet its exact requirements. This body is built with a double deck with a sheet of steel between the planking to keep the water from the melting ice dripping on the chassis mechanism, and it is drained at either side of the forward end. The sides may be removed to give a clear platform if desired. No canopy covers the body.

With the Reo power wagon the showing is remarkable because of the utility of the machine and its rapidity of movement. This vehicle is considered the equal of three single-horse carts, and with it one driver can do the work of three drivers of horses. The average mileage for a horse that is worked daily through the year, or the greater part of it, is 18, and this cannot move faster than a very slow trot under the most favorable conditions, such as when the cart is empty. The Reo power wagon has a maximum speed of 15 miles an hour and with a load of 1500 pounds it can be driven conservatively to do the work of a horse in two hours, if conditions favor. A horse could draw more than the wagon has capacity, but the greater speed of the machine more than compensates for this. The consumption of fuel is about a gallon to each 10 miles driven, and the oil consumption is about one gallon to 125 miles. The tires are 36 by two inches forward and 36 by 2.5 inches at the rear, a set costing approximately $75. The tire service varies greatly, because of the tendency to overload all machines, but 5000 miles is not an extreme. Contrasting the work of this class of power wagon and horse outfits the following figures are regarded as not being excessive. It might be said that some machines of this type, used for pleasure vehicles and driven much faster, have mileage of from 50,000 to 60,000 and are still doing good service. Obviously overloading is severe on the tires and this brings the expense of operation above that which might be realized with more attention to consistent loading. In this conclusion it is assumed that three full sets of tires are used annually, even the first year:



Horse Outfit—		
3 horses at $350 each	$1050.00	
3 carts at $250 each	750.00	
3 sets harness at $40 each	120.00	
Incidentals	25.00	
		$1945.00
Power Wagon Outfit—		
Power wagon complete	$ 650.00	
Incidentals	75.00	
		$ 725.00
Operating Expense, one year—		
Horses:		
Interest, 4%	$ 77.80	
Depreciation, 10% annually, horses	105.00	
Depreciation, 10% annually, carts	75.00	
Depreciation, 20% annually, harness	24.00	
Care and Maintenance—		
3 horses at $1 a day	$ 915.00	
3 carts at 33c a day	305.00	
Supplies	50.00	
	$1551.80	
Attendance—		
3 drivers at $12 a week each	$1872.00	$1872.00
		$3423.80
Power Wagon Outfit—		
Interest, 4%	$ 29.00	
Depreciation, 20% annually	145.00	
Insurance	50.00	$ 224.00
Care and Maintenance—		
Tires	$ 225.00	
Repairs	125.00	
Gasoline	172.00	
Oil	45.00	
Grease	10.00	
Supplies	75.00	
		$ 652.00
Attendance—		
Driver at $15 a week	$ 780.00	$ 780.00
		$1656.00
Difference in favor of power wagon		$1767.80

It will be seen that by this estimate the driver of the power wagon is paid more than the driver of the ice cart. To make this comparison it has been necessary to assume that the same work was performed every working day of the year, a condition manifestly impossible with ice dealers.

To understand the extremely variable character of the ice dealer's trade it may be stated that, assuming the demands of the summer business to be 100 per cent., for five months the volume may be placed at maximum, for four months of the year at 50 per cent. and for the remaining three months from 15 to 20 per cent. And there are periods when with all available facilities it is hardly possible to meet the demands.

With horse service with the shrinkage in business there can be little difference in the maintenance expense. If not worked the animals must be exercised, they must be given the same attention in the stable, and fed slightly less. There might be some saving in the expense of drivers, but this is the only possibility of economy.

With the truck and power wagon the saving is surprisingly large. Place the two in the garage, jack them clear of the floor, grease the exposed metal and wrap the tires

Reo Power Wagon as Loaded for Contract Delivery for a Lumber Firm.

to keep them from the light. The only fixed charges to continue are interest and insurance. It might be consistent to charge off a small percentage for depreciation and for tires, but there could be no other maintenance cost. Stor-

Digitized by Google

age must be provided for the machines, which would correspond to stabling for the horses.

The cost of the machines withdrawn from use would be not more than 10 per cent. of the operating expense, making a liberal estimate.

The cost of the animals when unproductive would be at least 80 per cent. of the normal expenditure, for depreciation is constant, it being possible only to make material saving in the reduction of attendance. In this respect there is a difference that is not apparent until analysis is made. Thus whether the power vehicle is working or not the variable character of its maintenance and care charge is an extremely potent factor in its favor. Of course the assumption is that the owner of any form of transport would desire to utilize it as much of the time as is possible, but where the conditions will not permit this the absence of operating expense is a decided advantage.

The Pocasset Ice Company has found it possible to utilize its truck and power wagon by making contract work of different kinds, and while there are limitations to the uses for which they are adapted because of body construction it is a fact that they are better than the carts employed for ice distribution, because such carts can be used for but one purpose, and to do contract transportation necessitates owning or hiring other forms of carts and wagons suited for such service.

SPEEDWELL COMPANY'S CAMPAIGN OF EDUCATION.

WORKING as a special representative of the Speedwell Motor Car Company, Dayton, O., H. Harry Croninger is travelling over the entire South on an educational mission, endeavoring to show the merchants and manufacturers of that region the exceptional advantages to be gained through motor vehicle delivery. His position is made clear in the following interview granted an Atlanta paper:

"First of all, let me impress the fact that I am not a salesman, nor do I wish to sell anyone a truck. My work in the South is purely educational. I want to investigate the situation and if possible interest the business men in the advantages accruing to them by the adoption of the commercial motor car for their delivery needs. It may be our truck; we hope it will be, but I am trying to show by arguments and figures the financial saving to be derived, whether it be the Speedwell or some other good machine.

"We are living in an age of progression; an age where modern methods of business are essential, and in every line of endeavor we discard the old and inadequate forms for the more recent ones that show a marked improvement—a bettering of production and service, and financial saving. The commercial motor car is one of the modern inventions that does show these things, and in the course of time it will entirely displace the horse and mule for delivery purposes, just as surely as the steam railway has taken the place of the old stage coach.

"The purchase of trucks by the large operating companies is made after a thorough investigation. They acquire this information from every state, and the accompanying compilation of operating costs is made up from records furnished us by owners. Unfortunately we cannot secure equal data regarding the cost of operating horses and wagons. Careful search and investigation have been made extending over a long period, but we fail to find any operating company or even individual that really knows what the cost a ton a mile is by means of horses. We therefore can only quote what many of the express companies and large merchants say—that a six-ton motor truck will make the same trip in about one-half the time of horses, and that four trucks with four drivers will displace eight drivers and 48 horses.

"Of course, economy depends entirely upon ton-miles, and unless the merchant has a tonnage he cannot effect economy. His advantage is then one of service and quick response to customers. It is recognized that the merchant who has at his command a means of instant service or delivery is the one who will get the business.

"The tenacity with which some business men cling to an old method of transportation is astonishing. Commercial conditions have demanded commercial trucks. A busy man would not consider taking a local train from New York to Chicago. He demands service and quickness, so he takes an 18-hour train. A few years ago we were content and considered it remarkable to cross the Atlantic in seven days. Commercial conditions and commercial men have forced better service, and today we find it of five and even less days.

"The motor truck comes under the same category, and the merchants and operating companies have forced the manufacturers to produce a means of rapid, dependable and economical transportation of merchandise, and are wondering how they ever got along without it.

"By the estimate herewith is shown clearly the economical point. It will be noted that I give $600 a year for upkeep, but with careful driving and a good service department a merchant can cut this down to $200 a year. This is a saving a ton-mile. He can cut his depreciation from 20 per cent. to 12. This is a possible saving a ton-mile. I figure $20 a month for garage expenses. If he use three trucks and has an equal space for six horses, this can be cut to $10 a month. This is a saving a ton-mile, but it is my idea to give a good, liberal estimate.

"We find that the cost of operating by horse and wagon is 36 cents a ton-mile. The following is the cost of operating a four-ton truck, based on 40 miles a day of 10 hours; six days a week; 304 a year; speed, 12 miles an hour; gasoline, 5.5 miles a gallon:

	A Mile
Gasoline, 11 cents a gallon	$0.020
Oil, etc., 30 cents a gallon	0.001
Repairs and replacements, including labor ($600 a year)	0.049
Tires (7000 miles guarantee)	0.066
Garage, $30 a month	0.028
Driver, $3 a day	0.075
Insurance ($3000 fire, $5000 liability, $1000 to others)	0.015
Depreciation, 20% on $3500	0.058
Total, a mile	$0.312
Total, 40 miles a day	$12.480

ECONOMICAL REO DELIVERY WAGON.

That the light delivery wagon is more economical and efficient in every way than the horse is well shown in a report received recently by R. E. Olds, president of the Reo Motor Truck Company, Lansing, Mich. The car was purchased by F. N. Rounsville, May 1, 1911, and an accurate record for the six months ending Oct. 31, shows that it covered 4553 miles, making 3773 stops. The expense for gasoline, oil and repairs was $78.86.

This is an average of 30 miles a day with a maintenance outlay of 50 cents a day, and less than 1.75 cents a mile. The earnings were $900.54, which means that the Reo truck not only earned its purchase price of $750 during the first six months of its use, but actually returned the owner a net cash balance of $150.54.

SPECIAL COAL DUMPING VELIE.

The matter of special body construction for differing lines of business is receiving renewed attention in all quarters. Lin McKie, manager of the commercial department of the Velie Boston branch, is showing a patented coal dumping body, recently placed in the market by the Velie Motor Vehicle Company, Moline, Ill., and fitted to a three-ton Velie chassis. The construction is such that the coal may be dumped from either side or the rear, and the body may be elevated to shute from any angle. It is built so that traffic will not be obstructed and is considered by many Boston coal dealers who have seen it to be a decided forward step in the matter of handling this product.

POWER WAGON ECONOMY IN LUMBER TRADE.

ECONOMY in the power wagon is assured to be chiefly in the saving of time, but there are other qualities hardly less important. The mechanical transport has established its value in service because of superior speed, and saving is material and is really larger than appears on the face of the comparison because this economy affects not only the drivers, teams and equipment, but includes the work of the men handling the lumber in the yard as well.

Sampson Four-Ton Truck with Roller Equipment for Loading and Unloading in Service of Shevlin-Carpenter Lumber Company, Minneapolis, Minn.

The truck as delivered to the company was with a longer wheelbase than is standard and the deck of the platform contained a series of rollers with longitudinal corrugations extending from one side to the other. These rollers support the weight of the load and on them freights of lumber are pushed forward or pulled backward with minimized effort. The rolls are seven in number and two are connected by gears with winch handles, by means of which the load is carried forward or backward as desired. The two winch rollers are at the front and rear with the gearing so compounded that a load may be moved with comparatively little effort.

With the utilization of the truck it was necessary to facilitate the loading and unloading and the handling in the yard, and to adopt methods that were somewhat at variance with tradition and custom, such as giving over the piling of the loads with the forward end above the driver's head and carrying the loads on inclines, although this method is still employed in loading long timber.

It was decided that the loading should be done so far as possible without the truck and to accomplish this a two-wheeled carrier with a long plank reach was utilized. These had been employed for moving material short distances in the yard and were found to be very satisfactory. The truck is loaded by the carrier and then driven to the point where it is to be unloaded. The carrier is then pushed off the truck and the load is moved forward by the rollers. The carrier is then run back on the truck and the load is ready for the next trip.

Sampson Truck Just Loaded and Piled Load Ready for Loading on Carrier in Yard of the Shevlin-Carpenter Lumber Company

experience in the use of these vehicles demonstrates that methods, aside from actual haulage, may be improved with corresponding returns.

The adaptability of the motor wagon is a large factor in its favor. Apparently there are no limitations in its use and besides the mileage that may be obtained and the larger loads conveyed, expedition in loading and unloading, that the machines may be kept at work with the briefest possible stops, is a logical requirement.

It is apparent that the long hauls are the most profitable with any conveyance. Stopping means lessening productiveness, and this leads to systematizing any attending labor so as to minimize waits and stops. Such organization is possible with motor wagons because of the regularity and dependability of the machines. To use a truck with a minimum of lost time has been very fully realized in the case of the Shevlin-Carpenter Lumber Company, Minneapolis, Minn., which is one of the largest concerns doing business in that section.

The Shevlin-Carpenter company has in its service a Sampson truck of four tons capacity and after experiment with it methods were adopted for unloading and loading which minimize the work and give decided satisfaction. The

Digitized by Google

tances about the yard. By piling or packing the lumber with one end on the axle of the carrier and the other on a wooden horse it was possible to make up loads at any convenient time, and to have these ready so that on the arrival of the truck it is backed to them and by use of the rollers and winches a load is carried on to the truck platform.

It will be apparent that the loading may go on at such a rate there is no delay on the return of the truck to the yard. The lumber is packed on the carrier and at a height so that the truck may be backed partly under it. Then the lumber is lowered by removing the horse and when the weight has settled on the geared roller a workman by simply turning a crank draws it on to the platform and forward as far as is necessary. The rear roller does most of the work loading and unloading, and the forward roller is employed merely to make the load snug and secure and to start it backward on the truck.

The load as packed is secured by a chain passed about it at the rear end, or that originally above the axle of the carrier, which retains it no matter what the movement of the truck. The vehicle is driven to the scene of the delivery and the place where the lumber is desired is learned. The machine is then backed or driven to this place and with the winch handles the rollers are turned and the load is backed off the platform until the rear end, retained by a chain, drops to the ground. Then the truck is driven ahead and the lumber dropped exactly where it is desired

Unloading Shevlin-Carpenter Lumber Company's Truck by Roller Equipment.

Load of Lumber Deposited in Stack Saving Time Usually Taken for Unloading.

and neatly piled, no further handling being necessary.

With this truck it will be seen that its loading and unloading is minimized so that the greater part of the time of the vehicle, with its power, speed and endurance, may be devoted to actual transportation. The fullest value of the truck is so utilized and the business of the firm is extended because it is possible for it to make deliveries at distances prohibitive with animal wagons. The illustrations show the manner of loading and unloading.

BOSTON'S PROTECTIVE DEPARTMENT.

A feature of public service in the larger centres, which is finding much favor in some of the smaller cities, is that known as the protective department, usually maintained in connection with the incorporated insurance companies doing business in the community. While in reality it is a part of the fire department and is so recognized as far as legal provisions are concerned, it is somewhat distinct, in that the various insurance concerns are assessed in proportion to the amount of premiums returned.

In Boston, for instance, the force consists of 61 men; a superintendent, three captains, two first lieutenants, four second lieutenants, 33 permanent men and 18 auxiliaries. A candidate for the force must be under 27 years of age; able to read and write English understandingly; a citizen of good moral character; have no record of crime against him; give references for the last five years; pass a rigid medical examination, and his appointment must receive the approval of the fire commissioner.

The corps is supplied with suitable apparatus intended to save life and preserve property at or after a fire. The work is principally that of preventing unnecessary water damage, and for that purpose the men spread 18 by 22-foot rubber covers, weighing from 35 to 45 pounds, over the goods and furniture on the lower floors. They also utilize several other appliances to carry off water, and when roofs are endangered they spread large "roof covers."

Boston has three separate commands. Company 1 covers the territory north and east of a line drawn from the West Boston bridge, through Cambridge, Anderson, Pinckney, Joy, Beacon, Park, Tremont, Bedford and Summer streets, including East Boston and Charlestown. This is served by two horse drawn wagons.

Company 2 has that section south and west of the previous boundary and extends to a line drawn from the Charles river through Massachusetts avenue, Southampton street and Andrew square to the water front, including that portion of South Boston not in district 1. This command has one automobile and one horse drawn wagon. Company 3 serves all that part of the city south and west of district 2, including Roxbury, Dorchester, West Roxbury and Brighton, and has two motor cars.

The horsed wagons each carry two 18-foot extension ladders and 25 covers. When more are needed they can handle about 50 at a load. The automobiles usually take about the same number, but of course, are able to carry a much greater supply when needed. The cars attached to Company 3 must make longer runs than any of the others, sometimes as great as seven miles. During the last year these machines covered 4365.6 miles in answering alarms.

So successful have the automobiles proven in this severe service, suggestion is made that insurance companies in much smaller cities would find it advisable to consider their use. Inasmuch as it is possible to do effectual work in saving unnecessary loss where runs of seven miles are undertaken, it readily may be seen that one car properly equipped would be able to cover the thickly settled portion of most cities and large towns. As has been stated, previously, it is a matter which is receiving much favorable attention in many localities at present.

NEW YORK BRANCH FOR MOTZ TIRES.

The Motz Tire & Rubber Company, Akron, O., has opened a branch for its Motz tires in New York City at 55th street and Broadway. E. P. White, formerly connected with the Goodyear Tire & Rubber Company, is the manager.

FIRE DEPARTMENT NOTES

The new year will see another piece of motor propelled apparatus added to the fire department at Indianapolis, Ind., as the delivery of a combined hose and chemical wagon is expected early this month. In the accompanying illustration is shown the automobile which was made by the American-La France Fire Engine Company, Elmira, N. Y., and which is fitted with a 40 gallon chemical tank and reel of hose as well as 1200 feet of 2.5-inch hose and usual equipment.

The vehicle is propelled by a four-cylinder, four-cycle, water-cooled motor with a 5.5-ton bore and six-inch stroke and is rated at 70 horsepower. Ignition is by Bosch dual system, including storage batteries, and the clutch is a multiple disc. The gearbox provides three speeds forward and reverse and final drive is by side chain. Pneumatic tires are fitted, single to front wheels and dual to the rear. The wheelbase is 140 inches.

The following cities and towns are considering or have appropriated money for the purchase of motor propelled fire apparatus: Lakewood, O.; Elmgrove, W. Va.; the Fire Fame Company, Wilmington, Del.; Dayton, O.; Sumter, S. C.; Kalamazoo, Mich.; New London, Conn.; Chambersburg, Penn.; Derby, Conn.; Meriden, Conn.; Waukegan, Ill.; Pasadena, Cal.; Terrell, Tex.; Rome, N. Y.; Newport, O.; Shreveport, La.; Bakersfield, Cal.; Ottawa, Ill.; Zanesville, O.; Mattoon, Ill.; Mankato, Minn.; Winona, Minn.; Charlotte, Mich.; Petaluma, Cal.; Sherman, Tex.; Masillon, O.; Fort Collins, Col.; Alberquerque, N. M.; Fort Wayne, Ind.; Manitowoc, Wis.; Everett, Wash.

Hose and Chemical Automobile Built by American-La France Fire Engine Company for City of Indianapolis, Ind., Which Will Be Placed in Service This Month.

Another point in favor of the automobile was brought out recently in New York City, which has installed many pieces of motor driven fire fighting devices. The water tower is the clumsiest vehicle to handle, especially when backing into quarters, and with horses the operation usually consumed 15 minutes or more. With the motor it is a simple matter for the chauffeur to straighten it out and back right in, as he has no horses to swing. And when the engine is in position the power is shut off and there is no need of further effort. Horses have to be looked after, and the harness suspended on the overhead supporters.

The residents of Thompsonville, Conn., turned out en masse recently when the Knox combination chemical and hose truck, made by the Knox Automobile Company, Springfield, Mass., arrived and was turned over to the fire department by Vice President Alvin D. Higgins of the Hartford Carpet Corporation, donor of the machine. The parade was headed by the Carpet City band, followed by the new machine after which were the various pieces of apparatus and members of the company. The line of march was through the principal streets and much red fire was burned in honor of the new vehicle. At the fire house the machine was formally turned over and the committee thanked the giver in an appropriate manner. The motor car is propelled by a 50 horsepower engine and is one of the latest turned out by the Knox company. It carries a 40-gallon chemical tank, also three-gallon hand extinguishers, and is fully equipped with fire fighting appliances.

White Plains, N. Y., has received a combination hose and chemical wagon from the Locomobile Company of America, Bridgeport, Conn., and the machine was designed and constructed for heavy service. The car is propelled by a four-cylinder, four-cycle, water-cooled motor with a five-inch bore and six-inch stroke and its horsepower is rated at 60. Drive is by side chains and a four-speed forward transmission is employed. The vehicle is painted white with nickel trimmings and will accommodate 10 men in addition to the driver. Two 35-gallon chemical tanks as well as hand extinguishers are carried. In addition to the 350 feet of chemical hose the equipment includes the usual fire fighting appliances. Irvington-on-the-Hudson has ordered a similar machine.

Waterloo, Ia., is said to be the first in that state to adopt the mechanically propelled fire apparatus, having contracted for a combination hose and chemical wagon to cost $5250. The special equipment consists of a 40-gallon chemical tank, and 12,000 feet of hose. The vehicle weighs 7200 pounds.

The Winnipeg, Man., fire department is advertising tenders for a second automobile hose wagon, and it is

Digitized by Google

stated on good authority that the city contemplates the conversion of the entire fire fighting outfit to motor vehicles.

The result of the first practical test of the automobile fire engine and hose wagon recently placed in service at Ottawa, Ont., was such that a fire loss was kept down to $500, which with the ordinary methods probably would have been at least $3000. The fire in question broke out in the attic of a large dwelling. A line of ordinary hose was laid on the outside of the building, while the chemical stream was utilized on the inside. The result was that the flames were extinguished with a loss confined almost entirely to the upper part of the house. Had water been used in the ordinary way, the damage to the lower floors would have been considerable. The chief of the department was well pleased with the result.

Two outfits of chemical fire apparatus, mounted on chassis made by the White Company, Cleveland, O., were submitted to a test by Commissioner Johnson of the New York City fire department recently. In order to imitate real conditions as nearly as possible a wooden structure was erected in front of the department's repair shop at 58th street and 12th avenue, being filled with shavings and dry wood, and the materials soaked with kerosene. The construction was such that a good draught prevailed.

Chemical Fire Apparatus Fitted to White Chassis Being Tested by New York City Fire Department.

When a match was applied it blazed fiercely and it was allowed to burn some little time to obtain a good headway, before word was given to the firemen to turn on the streams from the chemical wagons. Three minutes later it was merely smoking embers. The fire was checked so quickly and effectually that the entire outside walls of the structure remained in good condition, being simply charred. The accompanying illustration presents the automobiles and the scene of the conflagration.

West Haven, Conn., has found its first automobile fire engine so satisfactory that another machine is to be added and utilized as a flying squadron. The first wagon was severely tested and even driven through streets heretofore considered impassable for vehicles. Once the wheels sunk up to the hubs in a mudhole and the motor stalled. When restarted the engine backed the vehicle out, and in a second trial went through with a delay of but a few seconds. Two members of the department have been taught to operate the machine and others are being instructed for the purpose of driving the new motor car upon its arrival.

The members of the fire engine company of Pocasset, R. I., have made a request that the converted pleasure vehicle which was overhauled and painted recently be equipped with fire fighting appliances. If the authorities do not have the funds for this purpose the firemen propose to contribute the money.

Tire expense is an important factor in the cost maintenance of automobile fire fighting apparatus and in a recent letter to the Goodyear Tire & Rubber Company, Akron, O., Chief Mertz of the department of that city gives some data relative to this subject. The city placed a triple combination Webb apparatus in service in July, 1909, and the vehicle weighs 7800 pounds without men. Since that time it has covered approximately 2000 miles, and in answering alarms carries, on an average, six men and sometimes as many as 14. During the two years of use the shoes have not delayed the machine in responding to alarms and it is stated one of the casings contains its original air.

Lakewood, O., has passed an ordinance calling for a bond issue of $15,000 to purchase motor apparatus, and Elmgrove, W. Va., has authorized the purchase of a chemical wagon and hook and ladder truck, both fully equipped.

Fire Commissioner Johnson of New York City has written Mayor Gaynor, calling attention to the condition of some of the streets in the central portion of the city which are so bad that the automobile fire apparatus cannot use them. Many obstructions and breaks in the pavements are noted. The investigation is being made in view of the fact that within the next year 150 pieces of motor apparatus will be in service, as against 29 automobiles now being used.

Fire Chief A. V. Bennett of Birmingham, Ala., which city is replacing its horse drawn equipment with motor propelled apparatus, will add six more combination hose wagons to those already in service. The new machines will be similar to those being utilized with the exception that the motors will be more powerful. According to the chief the automobile is four times less expensive to maintain than the animal and during the first month of service, figures show that Hose Wagon No. 1 answered 45 alarms, traversed 578 blocks, used 55 gallons of gasoline, one of cylinder oil and .25 pound of grease. The total cost of this maintenance was $5.81. Another similar equipment answered 50 alarms, traversed 930 blocks, practised two hours, used 35 gallons of fuel, two of oil, .25 pound of grease, and changed a gas tank for $6.71. A converted steam engine answered 21 alarms, traversed 325 blocks, used 46 gallons of gasoline, about one of oil, one pound of grease, replaced dry batteries and a gas burner for $5.11.

MECHANICAL NOTES AND TIPS FOR DRIVERS

GENERATOR TROUBLES AND CAUSES.

Many commercial vehicles utilize a generator to supply acetylene to the headlights and while these devices are efficient when handled properly, they give more or less trouble if neglected. They require attention other than replenishing the carbide and water as will be explained herein.

Acetylene is composed of 12 parts of carbon to one of hydrogen by weight, or 92.3 per cent. of the former and 7.7 of the latter. Its density is about .91, and its weight at 32 degrees Fahrenheit is .073 pound a cubic foot. It is without color, has a strong odor, and is poisonous to breathe, in about the same degree as ordinary gas.

It is manufactured by combining water with calcium carbide, the latter being a mixture of coke and lime which has been fused in an electric furnace. The carbide is reddish brown and gray, somewhat crystalline, and decomposes

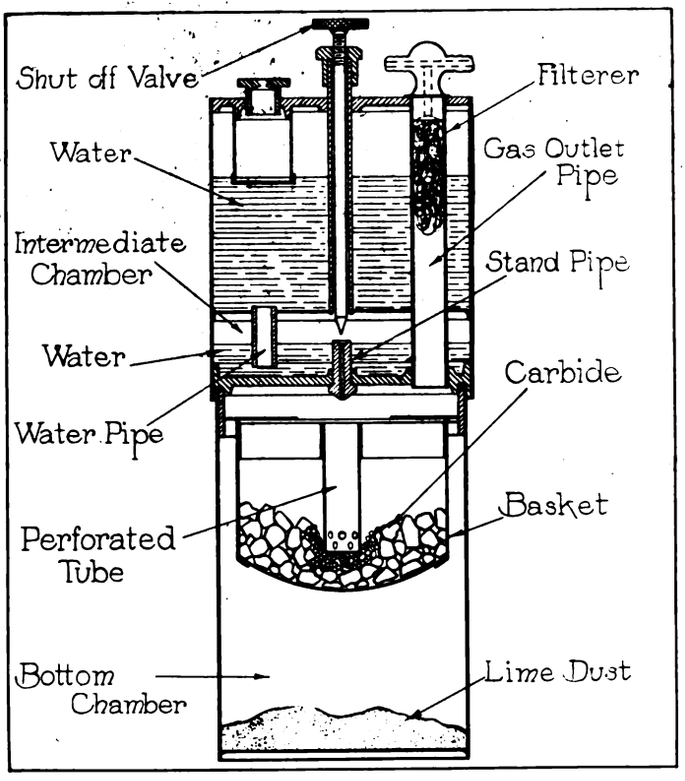

Fig. 1—Depicting the Components of a Conventional Type of Generator and Method of Operation.

in the water like ordinary quicklime, which it is in fact, when the calcium has combined with the oxygen forming oxide of calcium. At the same time the carbon unites with hydrogen, resulting in the desired acetylene.

Pure carbide of calcium will produce 5.4 cubic feet of gas a pound, but the commercial product rarely yields more than 4.5 cubic feet. This is the most brilliant illuminating gas known and will give a light of about 240 candlepower when burned at the rate of five cubic feet an hour, while good coal gas only results in 16 candlepower at the same rate of combustion. Acetylene can be reduced to liquid form at a temperature of 60 degrees by a pressure of about 600 pounds a square inch. It corrodes copper and silver but does not affect to any great extent, brass, iron, lead, tin or zinc.

If acetylene were burned with an ordinary jet, it would have a yellow tint as with illuminating gas, but when utilized in the lighting system of the automobile it is mixed with air. This mixing is brought about by the arrangement of the burner which is provided with openings for both the gas and atmosphere. Those of the former face each other, and when the acetylene is mixed with air by means of the other two apertures, the flames, when ignited, meet and form a fishtail blaze. The office of the air openings is similar to those employed on a gas cooking range, although the latter are much larger in size. This drawing in of the oxygen at the tip of the burner raises the temperature of the flame to a point where a white blaze is obtained. It is estimated that 1385 heat units are produced by the combustion of one foot of acetylene.

The generator employed on the motor car consists of a water tank, separate compartments for the carbide and gas, and a filter chamber. Water is dropped on the carbide by one of several methods, and as soon as the two come in contact, the latter begins to decompose, giving off gas as previously described. This collects in a reservoir, and by its natural pressure forces its way through the filter chamber, which is filled with cotton, wool or similar material, the carbon therein being arrested.

When the pressure reaches a certain point it is cut off and no more is generated until this falls again, allowing the water to flow once more. At Fig. 1 is shown a sectional view of a generator and the principles of regulating automatically the dripping of the water. When this is poured into the upper tank it runs down into the second chamber by means of a connecting pipe, and overflows the standpipe. If there be only atmospheric pressure in the lower compartment, water will drop freely into it. However, when the carbide is present, the first few drops reaching it will generate gas, the pressure of which is communicated through the standpipe to the middle chamber and forces a portion of the water back into the tank.

The gas escapes through a tube surrounded with water to keep it cool and is forced upward through a filter and one or more outlets. As it leaves the pressure in the carbide receptacle diminishes and the water in the middle chamber rises until it overflows the standpipe again, when the same process is repeated. Constant pressure is thus maintained whether one or more burners are being utilized. Thus it will be seen that an increase above normal stops the dripping of the water and that a fall below that starts the fluid.

When a generator is performing its proper functions the deposit of lime dust in the bottom of the receptacle will be dry. This denotes that the carbide is clean and in condition to respond to the next drop of water. If the burners and tubing be clear there should be sufficient gas at the tips to produce a good white flame. When there is a small flame at the jets and the pipes are free, and upon violently jarring the generator, this flares and then dies away, an examination of the carbide holder will show a dense, soggy mass, through which the water percolates with difficulty and the pressure is lowered. When the car is traversing smooth roads the wet lime, swollen to about the bulk of the carbide whence it originated, packs itself around the remaining lumps, with the same result. When the automobile gives a jolt, the packed mass is loosened, and the water rushes to the carbide causing a violent flaring at the burners. When the generator is shut off, and the lights continue to burn for some time, it also denotes similar conditions. To obtain satisfactory results the gas should be delivered to the burners clean, cool and dry and a filter is incorporated to catch the impurities and the generating chamber is water jacketed. If the vessel be left for a long

Digitized by Google

period there should be no deterioration of the carbide. If it dissolves it is safe to assume that the device is at fault.

In some types the drip of the water is regulated by wicks or strands of string. These may become clogged and usually are so arranged that they may be removed and cleaned. It is also possible that the filtering device may become fouled or that where drip pins are utilized they may have become bent or dirty and thus fail to perform their function. Lime acts as a heat retainer, causing the formation of tarry compounds from the gas, and when the lights are extinguished the water in the lime is sometimes sufficient to consume all the remaining carbide. It is essential that the lime should be separated from the carbide and should drop to the bottom of the container. It is also necessary that the perforated tubes around which is placed the carbide should be clean as well as dry to obtain the best results. If upon cleaning these members, and other working parts of the device, faulty operation should continue, it is best to ship it to the manufacturer.

Before condemning the generator it will be well to examine the tubing and the burners. The latter should be removed, making possible a test of the pipes for obstructions. Many drivers examine burners by blowing through them without closing the air apertures, and when cleaning them with a tire pump also fail to observe this precaution. There is a needle-like device upon the market for clearing jets which will facilitate the operation.

More or less moisture is present in the tubing, this being condensed from the gas. This occurs in the first 12 inches or so after leaving the generator and consequently the piping and rubber connections from the vessel should slope directly downward to the lowest point in the system and continue a foot or more in order to drain any possible moisture toward the generator instead of in the direction of the lamps. Satisfactory lighting is not obtainable with copper tubing although commonly used. It is too soft to hold its shape and consequently sags, forming pockets in which the condensation is likely to collect. This small piping clogs readily owing to the chemical action of acetylene on copper, which produces a black scale. The action is sometimes so rapid as to choke a .125-inch pipe in a few weeks. The proper material is brass, .25 inch inside diameter, although it is known as .125-inch pipe size. It is sufficiently large and stiff to hold its shape and does not clog easily.

In removing the residue of carbide that has become caked to the device it is bad practise to employ a file, a screw driver or any metal, because the residuum left by the carbide after the generation of acetylene attacks the copper of the receiver and chemically combines with it, forming a substance known as acetylide of copper. This is a highly explosive product and does not require much excitation to set it in action. If metal be used in cleaning, the process should be performed in water. A scraper of hard wood is preferable.

CARE OF STORAGE BATTERIES.

Many trucks are equipped with storage batteries either for starting or an auxiliary, and unlike the dry cell these require care and attention in addition to charging. They should be tested frequently and when the discharge limit of 1.8 volts a cell is reached they should be recharged. All corrosion should be cleaned from the terminals and these members treated with white vaseline or some anti-sulphuric acid solution. When the binding members are frozen and will not loosen easily, force should not be employed.

When the application of kerosene fails to move them heat will have to be applied, but care should be taken not to expose the lead of the lug to the flame. The best method is to heat a piece of metal and place it on the nut or screw member. The metal should not be too hot, but more at a black heat.

When the terminals of the wires leading to the battery are corroded, which is indicated by a green deposit, this should be removed and the metal covered with vaseline. As the corrosive substance is more or less a non-conductor of electricity it should not be allowed to gather. A little care in this respect will lengthen the life of the battery as well as increase its efficiency.

REPAIRING EXPANDING BRAKES.

Some cars are fitted with the expanding type of brakes and these may be metal to metal or lined with friction material. They are actuated by a cam which spreads the members designed to grip the drum of the wheel. The expanding device and faces of brake members may be so badly worn that but little friction is set up between the contacting materials. At Fig. 2 A is depicted a brake of the expanding type with the cam and faces in this condition and it is obvious that the member will not function properly.

A simple method of building up the faces is shown at B. The metal is drilled and tapped to take two cap screws and these may be adjusted to the opening required and then locked as outlined at C. Another method is to rebuild the faces with a strip of metal, the latter being fastened by machine screws. The holes for these members should be countersunk.

POPE-HARTFORDS DELIVER BREAD.

The Acme Tea Company operates a chain of over 200 stores in Philadelphia and suburbs, and in addition to its

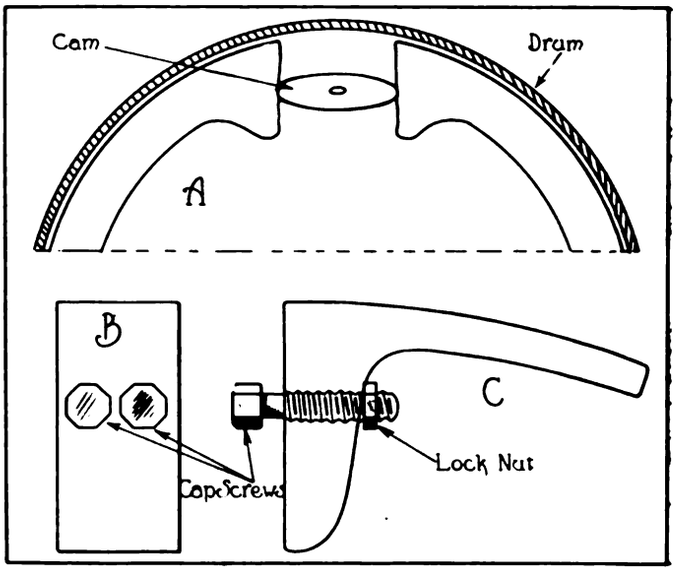

Fig. 2—Some Brake Hints: A, Expanding Type, the Cam and Faces of Which Are Worn; B, Repair Made with Cap Screws; C, Method of Adjusting and Locking.

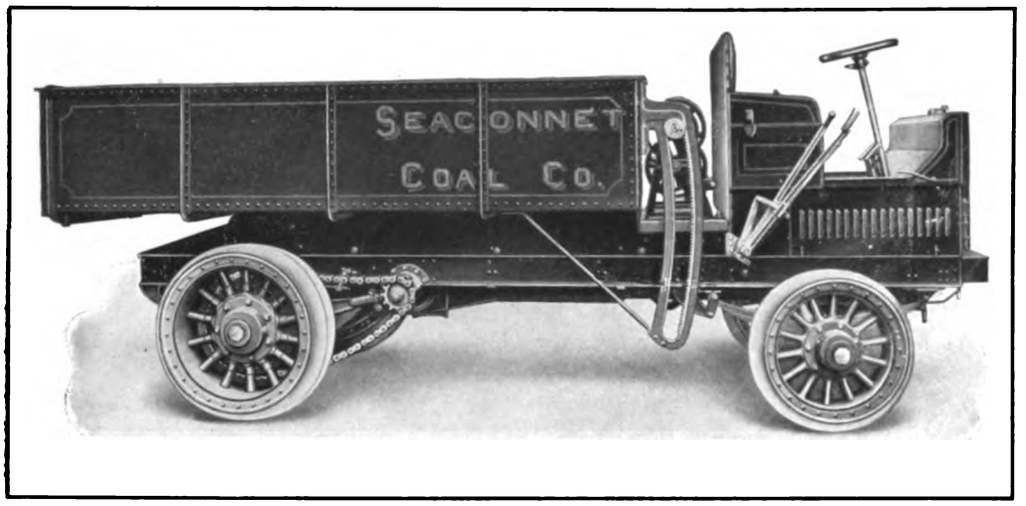
tea trade carries on an extensive baking business. Early each morning the freshly baked bread must be delivered to the various stores with regularity and dispatch. The company has in service two Pope-Hartford three-ton trucks, made by the Pope Manufacturing Company, Hartford, Conn., and will place the third in commission within the near future. After the day's supply of bread has been distributed the cars can then be used for the purpose of general delivery.



COMPETING WITH RAILROADS.

An effort is under way looking toward the organization of the Haverhill Auto Express Company, which is to operate a fleet of motor trucks between Boston and Haverhill, Mass. Two or three vehicles have been in service over this proposed line for some months making regular delivery of goods. The new plan contemplates the use of at least seven machines, to be started from Boston at one-hour intervals, beginning at 5 in the morning. These would deliver their loads in Haverhill and pick up shipments to be delivered on board the New York boats that night, reducing the time necessary to reach the metropolis by at least one full day.

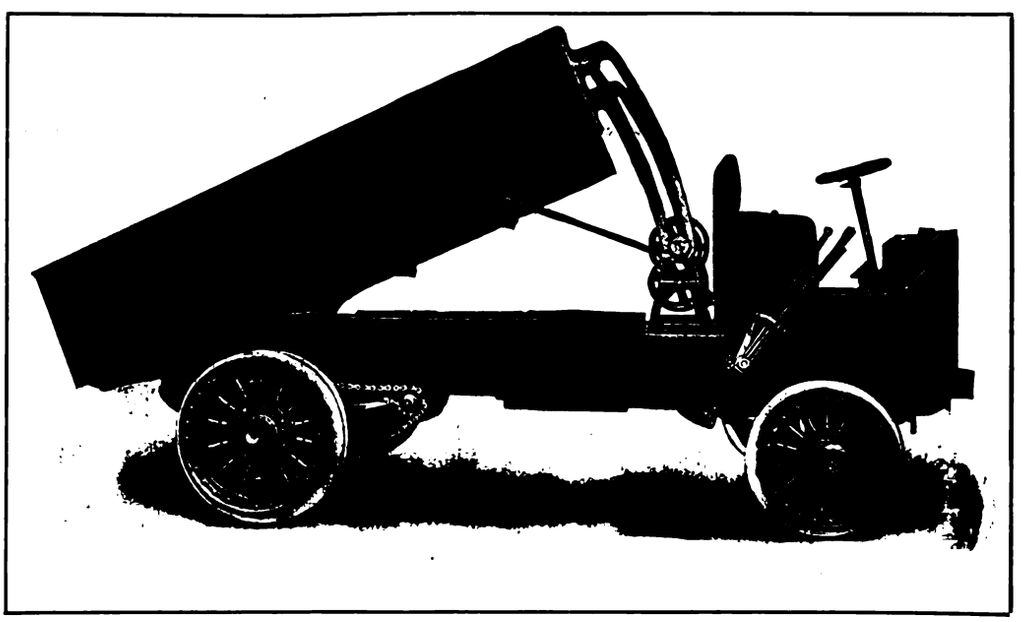
QUICK DUMPING WAGON AND TRUCK BODY.

HANDLING of the load is a problem of much importance in vehicular transportation. The minimizing of time and labor in loading and unloading has been given much attention. This applies to animal as well as power driven transports. Many devices have been perfected for unloading different materials and commodities from wagon bodies, some only useful for special service, and others more general in their application and use. Naturally those which may utilize the one equipment for the greatest number of purposes can be regarded as being the most serviceable.

Alco Truck with Monahan Dumping Body of Six Tons Capacity, Without Flare Boards, Utilized for Haulage of Coal.

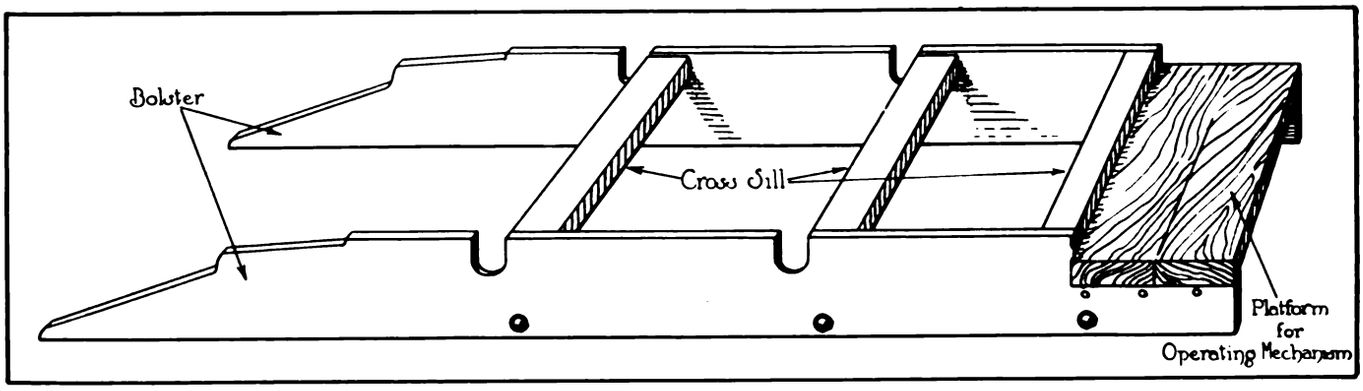


A body that has many qualities and features is the dumping outfit built by the Monahan Vehicle Company, Providence, R. I., with capacities ranging from two to 10 tons, and which bodies are used very broadly. This body is constructed of No. 10 steel plate, there being generally three and sometimes four plates forming the sides and bottom, and another the forward end, while the end gate is a separate construction that is suspended from the top of the sides at the rear end.

The proportions of the material differ with the capacity of the body, the allowance being 37 cubic feet for a ton of bituminous coal. It might be stated that 40 cubic feet is the accepted average for a ton in general merchandise transportation. This is, of course, exceeded when the bulk is large and weight proportionate to or less than bulk average.

This body is mounted on the chassis that the forward end may be elevated to give the body an angle of 42 degrees, considered sufficient for the gravity movement of all loads save under unusual conditions. To so elevate the body it is necessary to locate the fulcrum of the unloading apparatus practically above the rear axle, and that the rear end of the body may be lowered, the rear end of chassis frame is cut off. This means simply shortening the side members of the frame and restoring the end member and the reinforcements and stays.

The size of the rear wheels with practically every power wagon is such that the tires rise above the top of the frame side members and as it is necessary to have the centre of gravity as low as possible this construction necessitates a body that will have a width of about 66 inches at the forward end and 78 inches at the rear, with side plates at a height and length to give the required capacity. The rear end of the body must extend beyond the chassis frame from a foot to two feet. Perhaps 18 inches is a fair average. As the body is wider than the chassis frame, to elevate it sufficiently above the wheels to permit of full spring action a wooden frame is fitted with sides that in large bodies are 12 inches in height. From the fulcrum point to the rear of the chassis frame the sides of the wooden frame slope at an angle of 42 degrees. Forward of the body the sides of the bolster frame are cut to six inches in height. This space is heavily decked with oak for the installation of the hoisting mechanism, which is bolted to the frame. The entire bolster frame is left open to give fullest accessibility of the gear case, jackshaft, driving shaft, etc.



When the body is elevated it is supported by the hoisting gear forward and by two heavy hinges, one at either side of the chassis. These hinges are riveted to the bottom of the body and its frame and bolted to the bolster, the bolts passing through the bolster and the chassis frame. The hinges are milled so there is a precise fit. When the body is raised it is entirely clear of the bolster. Three steel members, the transverse shape and size of the body, are formed of T plates, these being with wings two inches wide and .3125 inch in thickness. Two other steel members are made in angle form with wings two inches wide and of the same thickness. The two steel angles form the end frames of the body and the three T plates the centre members, to which the body plates are riveted. The tops of the side and end plates are reinforced by a steel angle of the same proportions securely riveted. Across the rear end at the

Monahan Dumping Body Fitted to Alco Truck Elevated to Fullest Height for Unloading—Body Designed for General Haulage.

Digitized by Google

top is fitted a steel rod or bar which stiffens the construction and on which the end gate swings. The end gate is a steel plate reinforced as is the body, and when lowered it is held by a transverse bar which is constructed with two small lips which bear against the lower edge of the gate, which bar is operated from the side by a hand lever.

Plan of Bolster for Chassis for Installation of the Monahan Patent Dumping Body, Adapted in Proportions to the Size of the Frame and Body.

The hoisting mechanism consists of two racks attached to the forward end of the body, at the end of the transverse body plate, the lower end of the racks extending to about the height of the front axle. The ends are stayed by rods having angles of about 45 degrees riveted to the bottom of the body, close to the side, and to the body frame. While the body rests on the bolster normally it is possible to raise it easily by a crank which operates a succession of gears and pinions that mesh into the racks. This hoisting apparatus and the body are patented devices. It is claimed for the body that it may be elevated to its full height with any type of vehicle in less than two minutes and the load deposited wherever desired. The truck or wagon may be backed to any point and the load dumped, the body not being in contact with the ground. Obviously the lowering operation is quite as easily accomplished. Thirty-one revolutions of a hand crank raises or lowers the body.

Bodies of this class are built for hauling of coal, brick, stone, gravel, sand, building materials, ice, and, in fact, any commodity, including lumber, for the load may be drawn out when one end rests on the ground. All contents slide on the smooth metal floor of the body. These bodies have been constructed for vehicles in all parts of the country and shipments have been made to southern California by this company.

APPRECIATES TIRES AND SERVICE STATION

That the service stations of the United States Tire Company, New York City, are appreciated by the users of commercial vehicles is shown by several letters received by that company one of which is reproduced herewith. Writing from Springfield, Mass., the manager of the Saurer Motor Truck Agency, states: "I can recommend your tires with pleasure, as we have been using them on all our trucks for over 18 months and have had very few replacements; every one entirely satisfactory to our concern. We must also give your service station in this city much credit for the prompt attention that has been shown us on all occasions, our tires having been changed so that we have not lost any time."

SPEEDWELL DEALERS IN CONVENTION.

In an effort to improve the details of salesmanship with respect to its product in particular, the Speedwell Motor Car Company, Dayton, O., maker of Speedwell trucks, invited its dealers in all parts of the country to assemble at the factory, Dec. 11 and 12, paying their expenses both to those concerns which unquestionably will profit by their use, and that cars should be so represented previous to the sale that the purchaser will be acquainted with every probable item of expense connected with their operation and maintenance. This convention is indicative of the thorough manner in which this concern is pursuing the matter of sales.

SAMPSON IN TELEGRAPH SERVICE.

The commercial vehicle has invaded another field and this time it is the telegraph division of the Detroit fire department. The authorities conducted a series of tests with a 3000-pound Sampson truck, made by the Alden Sampson Manufacturing Company of that city, a constituent of the United States Motor Company, New York City. The car was commissioned to deliver supplies to all of the fire stations in the city and completed the circuit in eight hours. A team of horses required from two to three days for the same work.

The telegraph division uses the machine to draw cables through underground conduits and in the accompanying illustration is shown the apparatus at work. A winch, driven by the power of the motor, and operated by a lever, winds

Power Driven Winch Utilized on Sampson Truck for Drawing Cable by Detroit Fire Department.

the cable, superseding the slower method of a hand windlass. The automobile is in service night and day and in addition to replacing the horse equipment formerly employed, performs work that required additional teams.

POWER WAGON AMBULANCE AND HEARSE.

THE requirements of those who desire to utilize motor vehicles for business purposes are such that specialization in body equipment for standard chassis is becoming more and more necessary. Those who have need of bodies for commonplace service often seek something distinctive in design and yet absolutely serviceable and enduring.

An excellent example of the possibilities in work of this character was recently delivered by the Monahan Vehicle Company, Providence, R. I., to J. P. Cleary & Son, Boston, Mass., this being installed on a Sampson 1500-pound power wagon chassis and purposed for a combined undertaker's ambulance and wagon.

The chassis was sent by the builder to the works at Providence where the body was designed and constructed. The accompanying illustration gives an admirable idea of the general design. The body is eight feet in length and 48 inches wide, with the sides of the seat enclosed and the roof carried forward of the dash nine inches. The sides of the body proper are unbroken and are finished with molding that forms panels, the upper and lower being wide and the centre one narrow. In the centre panel is a large plate bearing the firm name. The finish is plain and in black.

At the rear is a step carried on brackets and above this

Specially Built Body for a Combination Ambulance and Hearse Installed on a 1500-Pound Sampson Chassis.

double doors open outward, these doors being fitted with windows that drop into the lower section. At the front of the body and behind the seat for the driver is a window that swings from the roof and which lifts inside the body, where it may be hooked if desired. The interior of the body is the natural wood and at the sides are racks, raised or lowered as occasion may demand. The floor may be removed for ready access to the chassis mechanism, and rollers are fitted to the sections for the easy removal of any load that may be carried. The body may be closed tightly as protection against dust in the event of a lengthy trip.

The sides of the body are carried forward to enclose the sides of the seat, a lengthy bracket supporting the extension of the roof. Into the sides are fitted large lights of heavy plate glass, affording the driver a view of either side of the way. The foot room in front of the seat is ample for comfort and the cushions and back of the seat are luxuriantly upholstered in tufted leather.

The protection of the long hood can be increased by the use of a storm front or windshield and in cold weather one or the other will be used. The control is at the left side, this being especially adapted for service in traffic. At either side of the body, back of the seat, are installed side lamps, while on the dash is carried another set. They are all oil-burning. All of the fittings are nickeled, that being more in keeping with the service for which the wagon is intended.

The absence of running boards, the short fenders and the single step at the side, with the muffler carried crosswise back to the dustpan, impresses one as being odd, but there is nothing unsightly in the appearance of the chassis, while the body is thoroughly commendable from every point of view.

WHITE ENGINEER STUDIES FOREIGN CABS.

M. F. Melhuish of the White Company, Cleveland, O., recently returned from a tour abroad, during which he visited all the principal European cities for the purpose of studying the construction and plan of operating motor driven public service conveyances This concern has announced its intention of making the production of taxicabs and motor 'buses a definite part of its business.

Mr. Melhuish states that in London alone there are 7200 taxicabs in daily operation, but he would not venture to estimate the number of motor 'buses there. The motor practically has displaced the electric street car in that city. The General Omnibus Company, one of the largest concerns in London, has its own factory where it makes its cars complete, producing at least 20 cars weekly and utilizing all of its product on its own lines within the city.

He holds that one of the chief reasons why taxicabs are so much more common in European cities than in America is that it costs only a fraction as much to ride in them there as it does here. In London, the fare for riding in a motor 'bus is twopence, or four cents in American money. No transfers are given and if a passenger wishes to travel beyond the end of any particular line he must pay an additional fare.

The type of motor 'bus used in London is very similar to the double-decked vehicles which are so familiar as a part of the traffic on Fifth avenue in New York City. Each is marked to denote the territory it covers, much the same as our street cars.

The rider in a taxicab in London pays only 16 cents for the first half-mile and four cents for each additional half-mile. This explains the otherwise amazing fact that there are 7200 taxicabs in that city.

Most of the London cabs are equipped with four-cylinder engines because of the hills in some districts, but in Paris where the streets are almost invariably level, the vehicles have one and two-cylinder engines. To the American eye, the London taxicabs are much more sensible than those of Paris and other European capitals, where the body design usually seems "freakish."

The London branch of the White Company is reported as thriving. It will surprise many people to know that it employs 300 men in its factory department. When White cars are sold in Europe, the home office ships the chassis only to its London branch. There they are fitted with bodies conforming to the style suitable for that particular section in which the car is finally to be delivered.

FIRST AMERICAN-BUILT COMMER.

The distinction of purchasing the first Commer truck made in this country by Wyckoff, Church & Partridge, Inc., of New York City, belongs to the Eagle Storage Warehouse of Brooklyn. This concern already has one Commer, imported by the American agent last summer, and it has been doing such good service that a repeat order was given for the first vehicle produced by the new factory. It will be a duplicate of the English product, all the jigs, tools, dies and patterns having been imported for this purpose. It will be of the 4.5-ton capacity and fitted with the regular van body. The American product will be designated as the W. P. C. Commer. The Boston agent has claimed the second machine.

The Mogul Truck Company of Chicago was incorporated recently for $125,000. The incorporators include G. C. Griffiths, J. S. James and F. Rawson.

The Motor Cab Company of Boston has been incorporated for $1000. Otto A. Lawton of 31 Irvington street, Boston, is named as president and treasurer.

The M. & P. Electric Vehicle Company was incorporated in Detroit recently for $10,000. Myron C. Messiman and Burton Grandy are named among the incorporators.

The Wishart-Dayton Auto Truck Company of New York City has been incorporated for $25,000 and the incorporators include R. A. Inch, S. E. Wishart and J. B. Smith.

The Electric Motor Car Company, recently organized at St. Louis, Mo., will handle electric commercial vehicles equipped with the Walker balance gear drive.

The Federal Motor Car Company, Chicago, has been incorporated for $10,000, the incorporators including C. W. Rhodes, David B. Rosenthal and Leo S. Kositchek.

The Amalgamated Motors Company, Los Angeles, Cal., was incorporated recently for $500,000. The directors named are as follows: C. B. Croner, C. J. Schroeder and J. L. Kirkman.

The Buffalo Motor Vehicle Service Company, Buffalo, N. Y., has been capitalized for $100,000 with the following incorporators: W. R. Huntley, J. H. Vail, C. R. Huntley.

The B. Gerdelman Manufacturing Company, St. Louis, Mo., has moved into new quarters on Washington avenue, near Walton. The new building was completed recently.

The Wachusett Cab & Automobile Company, Kittery, Me., was incorporated recently for $5000. Horace Mitchell is named as president and treasurer, and C. E. Smothers as clerk.

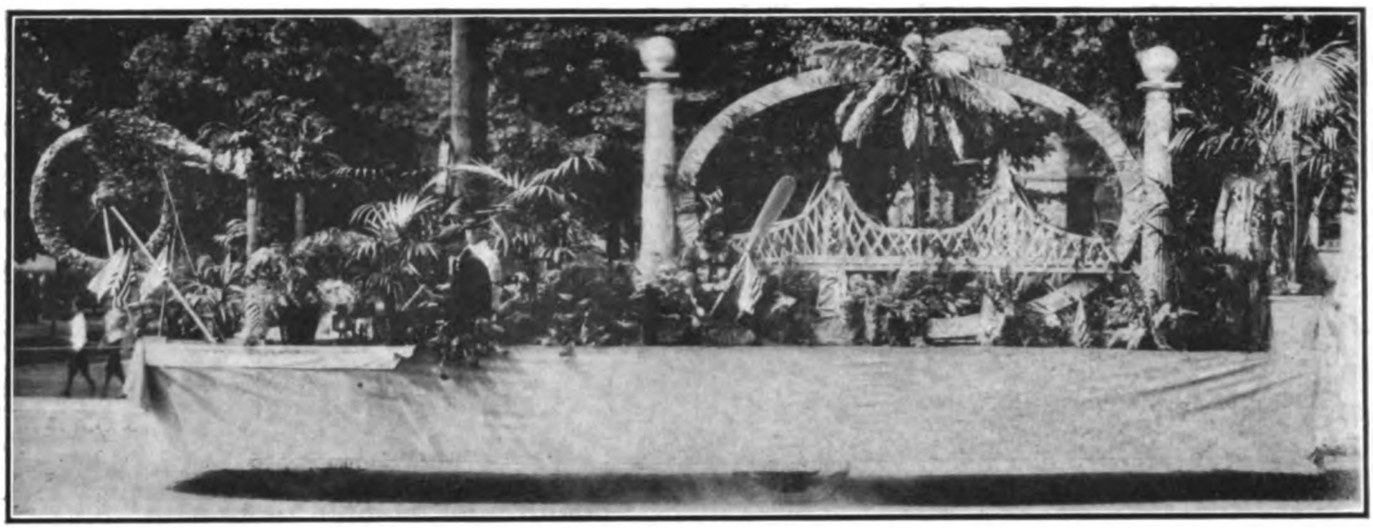
The Motor Accessories Manufacturing Company, Marshalltown, Ia., has been incorporated for $10,000, the incorporators including Charles C. Eldridge and Edwin J. Beebe.

The L. A. Mitchell Company, Jacksonville, Fla., has taken the agency for the Dayton truck. W. A. Baxter, special factory representative, visited the new agents recently.

Frank A. Babcock of the Babcock Electric Carriage Company, Buffalo, N. Y., was a visitor in Boston recently, where he was entertained by the Electric Vehicle Club of that city.

William C. Durant was given a banquet recently by the business men of Flint, Mich., in recognition of his making that city one of the leading automobile centres of the country.

The Motor 'Bus Company of Chicago has been incorporated for $60,000 and will operate and maintain motor 'buses. The incorporators include Clarence E. Morris and Frank P. Page.



The American Silent Motors Company was incorporated at Los Angeles, Cal., recently, for $2,000,000. The directors named include Benjamin Waterfall, R. J. Connors and Ernest Kouwenhoven.

The Royal Automobile Machine Company, Brooklyn, N. Y., has been incorporated for $10,000. The incorporators include Sydney Solomon, Celia Rothstein, Louis B. Brodsky and William M. Abel.

The White Garage Corporation, Los Angeles, Cal., has been incorporated for $100,000. The incorporators named are: F. Fay Sibley, Martin E. Tew, R. Roy Sibley, C. M. McCully and E. L. Sibley.

The Batavia Company of Pennsylvania, New York City, has been incorporated for $30,000, and the incorporators named include H. W. Newburger and M. Lustig of that city, and D. Weiss of Yonkers.

The Kissel Kar New England Branch has moved to 10 Columbus avenue, Motor Mart, Park square, Boston. These quarters will be occupied until spring when the new building will be completed.

Three-Ton White Truck, a Feature of Parade Held Recently in Honor of Opening of a New Bridge at Pittsburg, Penn.

The Goodyear Tire & Rubber Company, Akron, O., has removed its St. Louis, Mo., branch from Olive street to Locust. The new building is one of the most complete of its kind in the Southwest.

The National Spring Tire Company, Chicago, was incorporated recently for $125,000. The incorporators named include Charles L. Sigmann, Jr., Louis Valence, Charles H. Jackson and F. J. Karasek.

The Boulevard Company, Waterbury, Conn., has been incorporated for $5000. The officers consist of: President, William E. Russell; vice president, Lizzie M. Russell; treasurer, Albert Delay; secretary, Charlotte M. Delay.

The Krupp Motors Company, Wilmington, Del., has been incorporated for $250,000 and will manufacture motor vehicles and parts. The incorporators include D. Morgan, G. H. Anderson and James McMorran, all of Pittsburg, Penn.

The Stover-Lang Company of Boston has been incorporated for $40,000 to sell speed and mileage meters. The directors are: President, George H. Lang; treasurer, Charles L. Stover, 221 Columbus avenue, Boston, and Norman F. Pratt.

Col. Grantley P. Postles has leased the garage and show rooms at 220 West 10th street, Wilmington, Del., and will han-

Digitized by Google

dle commercial and pleasure vehicles. Henry G. Kurtz, agent for the Mack truck, will be associated with Mr. Postles.

The Autocar Sales & Service Company of Philadelphia, will establish a branch at 714 Orange street, Wilmington, Del., where a full line of commercial vehicles will be carried and a service station maintained for the users of Autocars.

The Atlantic Auto Truck Transportation Company, Haverhill, Mass., has established quarters at 65 Water street and will conduct a general transportation business. One machine is now in service and the addition of others is contemplated.

F. H. Quick, formerly with the Gibson Auto Company, Indianapolis, Ind., and the United Motors Indianapolis Company, has joined the sales force of the Findeisen & Kropf Manufacturing Company, Chicago, maker of Rayfield carburetors.

Grant L. Egan has resigned as advertising manager of the Motor Car Equipment Company of New York City and will hereafter devote his energies to general advertising with the Catalog Publishing Company, World building, New York City.

The Miles Motor Tire Company, capitalized at $200,000, has been organized and will erect a plant at Braddock, Penn. The incorporators are: Charles W. Dressler, Thomas C. Aten, Charles L. Balyser and Zenab A. Delwarts, all of Braddock; Frederick Miles and M. R. Myers.

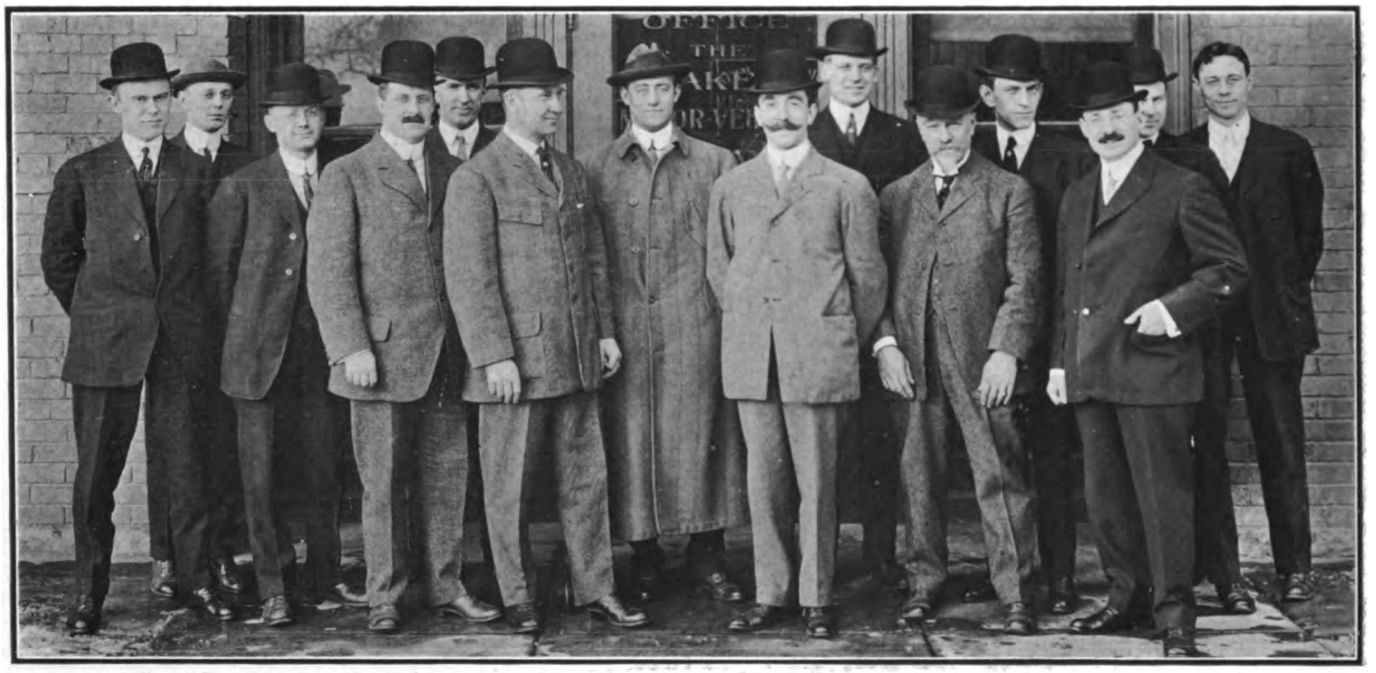
George L. Sullivan, recently automobile editor of the New York Tribune, has joined the sales department of the American Locomotive Company, New York City, and will be associated with Harry S. Houpt, manager of the Alco branch in that city.

The Parker Motor Wagon Company, New York City, has been incorporated for $10,000 with the following named as incorporators: Harry C. Cottfried, Drew McKenna and Charles E. Wood, 605 West 147th street, New York City.

The American Adjustable Wheel Company, Inc., Richmond, Va., was incorporated recently for $100,000 and will manufacture an adjustable motor car wheel. The officers named are: President, R. H. Bruce; vice president, Clarence Vaden; treasurer, J. H. Pinner; secretary, J. C. Davis.

The Merchants' Auto Company, Indianapolis, Ind., announces a change in its garages. The Delaware street quarters will be utilized for commercial vehicles while the repair shop and battery charging station will be located on Pratt street. E. Frank Brown has succeeded H. B. Stout, Jr., as manager.

Bosch magnetos, made by the Bosch Magneto Company, New York City, were well represented at the Olympia show, held in London, England, recently. According to the company, of the 599 magnetos shown 488 were Bosch, 81 per cent. of the total. The balance of 19 per cent. was divided among 10 other makers.



The Mack Motor Truck Company of St. Louis, Mo., has been organized and will act as distributor for the Middle West for the Mack Bros. Motor Car Company, Allentown, Penn. The officers of the new company are as follows: President, William R. Bush; vice president, Cecil G. Fennell; secretary, F. J. Bush; treasurer, Knox Tuassing.

The Virginia Automobile Garage & Repair Company, Norfolk, Va., has opened an extensive repair shop at 158 West Main street, and is prepared to handle all types of motor vehicles. The officers of the new company are as follows: President, H. L. Page; vice president and general manager, Archie M. Bopp; secretary and treasurer, P. A. Page.

The Velie Motor Vehicle Company's Chicago branch has closed a contract for the sale of Velie commercial and pleasure vehicles with the Columbia Garage, 335 West Madison street, Chicago. The latter will operate a service station for the benefit of the West Side trade, and will work in conjunction with the Chicago branch at 1615 Michigan avenue.

The Remy Electric Company, Anderson, Ind., maker of ignition and lighting devices, announces the absorption of the American Headlight Company and also has purchased outright all patents, designs, good will and manufacturing rights of the Peters Electric Headlight for steam locomotives. New buildings will be erected at Anderson to care for this production.

A White three-ton truck, made by the White Company, Cleveland, O., was one of the features of a street parade held recently in Pittsburg, Penn., to celebrate the opening of the new Sewickley bridge. The machine was attractively decorated, as indicated by the accompanying illustration. It was entered by the Joseph Horne Company. Twelve other White automobiles were represented.

Salesmen Representing the Interests of the Baker Motor Vehicle Company Who Attended Convention at the Factory of That Concern Recently.

E. P. Horton, who was recently appointed manager of the United Atlanta Company, Atlanta, Ga., southern branch of that division of the United States Motor Company, has been prominently identified with the Maxwell organization since 1904. He went to Atlanta from Syracuse, N. Y., where for the past three years he has been manager of the branch in that city.

The Baker Motor Vehicle Company of Cleveland, O., held a convention lately attended by commercial car salesmen from various parts of the country representing New York, Boston, Chicago, Buffalo and Newark, N. J. The event occupied three days, one of which was devoted to a discussion of the different problems which confront salesmen in the commercial car field and another to inspecting the factory. In the accompanying illustration is shown some of the party at the plant.

C. F. Splitdorf, New York City, maker of Splitdorf magnetos, has been making extensive alterations and changes in the branch houses of that concern throughout the country, these being necessary by the increasing business. Following new quarters in Chicago and the establishment of a branch house in Kansas City, Mo., the old location in San Francisco, Cal., has had to be abandoned owing to the lack of proper facilities. P. E. Kempton, branch manager on the coast, will be located in the future at his new headquarters, 430-36 Van Ness avenue, San Francisco.

DISCUSSING ANTI-FRICTION BEARINGS.

Mr. Thomas Takes Exception to Some Statements Made by Authors of Previous Article--Mr. Page Makes Reply, Answering All Criticisms.

IN THE December issue of MOTOR TRUCK there appeared an interesting discussion on the use of anti-friction bearings for worm gearing by Victor W. Page, M. E., and A. F. Rockwell of the New Departure Manufacturing Company, Bristol, Conn., concerning which H. Kerr Thomas of the Pierce-Arrow Manufacturing Company, Buffalo, N. Y., appears to take some exception. Desiring that the authors of the article in question should have full opportunity to answer Mr. Thomas, his letter was forwarded to them. The entire correspondence is presented herewith, and it is believed that the readers of MOTOR TRUCK will find the continuation of the discussion quite as interesting as the original.

Editor MOTOR TRUCK,
Sir:

With reference to the interesting article on anti-friction bearings for worm gearing appearing in the December number of the MOTOR TRUCK, the author raises one or two points which, I think call for some criticism.

In the first place, he bases a number of arguments upon the statement, "The lower the pressure, the more efficient the gearing." This statement is in opposition to facts which are accepted with regard to friction. Unwin, basing his arguments on the mass of data obtained by what are known as the Beauchamp-Tower experiments of the Institution of Mechanical Engineers, clearly shows that the co-efficient of friction between two metals running in oil bath lubrication is directly proportionate to the square root of the rubbing velocity and inversely as the bearing pressure. In other words, when the bearing pressure is increased, the co-efficient of friction falls as it also does when the speed of the rubbing surfaces is decreased.

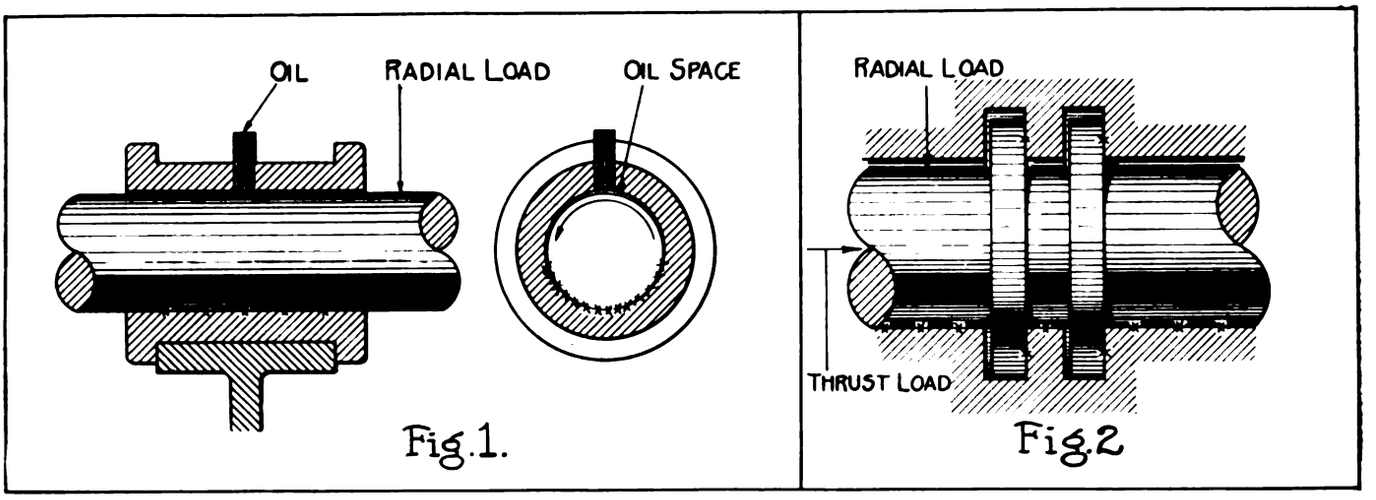
Coming to the calculations affecting loads of the gearing, I regret that I cannot follow how some of the results are obtained. The final figures with regard to the pressures on the worm teeth are much lower than anything I have ever come across. Thus the load on the worm teeth in the examples the author quotes is given as 328 pounds. This should be, in my opinion, very much higher and if the engine at 47 horsepower, which the author refers to, is exerting its full power, it should be sufficient to skid the wheels of say a fully loaded five-ton truck, and the load will be nearer to 30,000 pounds than 300 pounds.

It is possible that I have misread some of the figures in the article but as others may do the same, it appeared desirable to ask your correspondent for some further information as to how his figures are obtained.

With regard to the method of supporting the worm, the examples given in Figs. 2, 3, 4, 5, 6, and 8 in the December issue of the MOTOR TRUCK, are all undesirable. No worm gear has ever been constructed which will work without some rise in temperature and the elongation of the worm spindle with this increase will cause a very destructive effect on the ball races unless they are assembled in the first place with an amount of back lash which would be found highly objectionable. The examples given in Figs. 7 and 9 in the same issue are correct but in this respect, as the spindle is held against the thrust in either direction at one end only and is consequently free to expand as much as necessary.

I have not any experience myself with the special form of combination ball bearings described in the article but their application is exceedingly interesting. Their failure, however, would be almost a foregone conclusion if they were only provided of such strength as would be proper for the loads mentioned in the article.

I trust that some further information on the points raised may be forthcoming from the author.



Yours truly,
H. KERR THOMAS, A. M. I. MECH. E.

Buffalo, N. Y., Dec. 19.

Editor MOTOR TRUCK.
Sir:

I beg to acknowledge receipt of your communication of recent date with enclosure and desire to thank you for giving me an opportunity to correct the erroneous impressions which are present in the mind of Mr. Thomas. I believe that a more careful reading of the article in question would have eliminated some of the criticism which Mr. Thomas offers. The statement to which he seems to take special exception is: "The lower the pressure; the more efficient the gearing and the more easily lubrication can be maintained. There is also less thrust on the bearings and consequently less power consumed by friction".

The argument which Mr. Thomas uses to support his contention is taken from data which has been accepted by many engineers and which holds true only when speaking of journals which are operating under ideal conditions as regard lubrication. If one reduces the quantity or certainty of lubrication, one will obtain radically different results, as will be evidenced by the accompanying table which was compiled from the same Beauchamp-Tower experiments in which Mr. Thomas seems to place so much reliance.

Demonstrating Different Conditions Which Prevail in Oiling Journal and Collar Bearings—Note Difficulty in Forcing Oil Film Between Surfaces of Thrust Collars Which Are Held Tightly Against Corresponding Faces of Bushing.

Oil Feed, drops per min.	Co-efficient of friction	Load, lbs. per sq. inch.
79	.008	20
82	.0054	40
80	.0053	60
83	.0063	80
98	.0077	100
84	.0083	120
90	.0093	140
84	.0113	160
	seized	260
	seized	300

Table Taken from Beauchamp-Tower Experiments with Plain Collar Thrust Bearings Which Demonstrated Gradual Friction-Coefficient Increase with Augmenting Pressure at a Rotative Speed of 128 Revolutions a Minute with Nearly Constant Lubrication.

Digitized by Google

If the paragraph in question is read closely it will be evident that it related to thrust loads and bearings and in speaking of the efficiency of the gearing, the writer meant the entire group, including worm, worm wheel, and supporting bearings. The frictional loss for well lubricated journals must be considered from an entirely different viewpoint than that governing the action of dry, semi-dry or even surfaces between which lubrication is uncertain. It is difficult for one to define accurately where one condition begins and the other ends. The laws upon which operation of the journal bearing depend cannot be applied to those of the step or collar type which are adapted only to sustain thrust. In the well oiled journal bearing the friction resistance must obviously conform to the laws of lubricated surfaces, on the other hand if the supply of lubricant is intermittent, as the quantity of oil diminishes the resistance will tend to conform to the laws for dry or unlubricated surfaces. Another law of friction which may be recalled by Mr. Thomas relates to that existing between dry surfaces: "The friction between dry surfaces under moderate loads and low velocity increases directly as the normal pressure between them".

Between two extremes is the condition of uncertain lubrication and this is the one in which worm bearings most often run, when the worm is placed at the top of the rear axle housing. It is practically impossible to immerse it in an oil bath because if light oil is used it will run out at the ends of the axle shafts as its most common placing is directly on the rear axle. Practise seems to be about evenly divided between different engineers as to whether the worm wheels should be at the top or bottom of the axle housing. Where very large traction wheels are fitted, as is possible on the motor truck, the worm can be housed very easily under the axle as the requisite ground clearance can be obtained very readily and oil bath maintained.

The writer does not intend to take issue with Mr. Thomas' statement regarding the law of friction but at the same time it will be evident that worms can not always work under ideal conditions. In stating that "lower pressures make for greater efficiency", the writer was referring specifically to the question of maintaining an anti-friction oil film between the surfaces of the worm teeth or the thrust bearings if of the plain collar type. Careful perusal of the article under discussion will show that this was the type that the writer demonstrated would consume considerable power. If bearings of this kind are used it will be evident that high pressure tends to squeeze out oil and if the pressure is unduly high it would be difficult to maintain a sufficient supply of oil between the surfaces. If the oil film does not exist between the surfaces it will be apparent that any bearing will be practically in metallic contact with its journal. Under these conditions the co-efficient of friction would be nearly that of the dry surfaces in contact which for steel against bronze is given at .152 instead of .053 as would be the case if lubricated with light oil.

There are certain pressures at which any oil film will tend to break down and obviously, lubricant cannot be introduced between bearing surfaces if the oil film pressure is greater than that of the head of the feed. Experiments have shown that increasing the load will alter the oil pressure which falls and rises in exact proportion as the load diminishes or augments. The statement that low pressure is more desirable than high pressure between surfaces can be substantiated by common mechanical engineering practise. If the theory formulated by Mr. Thomas regarding friction reduction as pressure is augmented held good in practise it would not be necessary for machine designers to increase the size of bearings to care for bigger loads. If one wanted a practically frictionless bearing all that would be necessary would be to subject it to extremely high pressure. This might produce a condition in that a bearing which showed considerable friction under a load of 500 pounds could be practically frictionless by imposing a stress of twice or three times that amount.

Let us see how authorities look upon such hypothesis as formulated by my critic. Alford, in his book, "Bearings and Their Lubrication", says the following in regard to the friction of thrust bearings of the plain collar type: "The co-efficient of friction for a collar bearing is higher than a journal bearing running under similar conditions. In such bearings there is little or no action tending to introduce oil between surfaces as in the journal bearing. The friction co-efficient for collar bearings approaches that of a journal bearing running at low velocity and with poor lubrication. It may be taken as .04 to .05. Experimental data tends to show that the co-efficient is independent of the speed of rubbing and decreases with an increase of load." This latter bears out Mr. Thomas' statement but note how it is qualified. Again quoting Mr. Alford: "At the same time this type of bearing is only suitable for comparatively low pressure and comparatively low rotative speed unless the bearing surfaces are separated by a film of oil maintained by forced or positive feed lubrication".

The condition which actually obtains when collar type thrust bearings are used can readily be compared to those which exist when the ordinary journal bearing is employed. Referring to sketch Fig. 1, herewith, it will be seen that under a radical load, a shaft running in a plain bushing will be thrust against the bottom as indicated by the crosses. As all such bearings are fitted with a running clearance varying from .002 to .005 inch it will be evident that there exists on the unloaded side an amount of space which will permit oil to feed constantly against the bearing surfaces. The rotation of the shaft tends to carry lubricant between the surfaces in contact and thus maintain an oil film at the points where the load is applied.

Let us compare these conditions with the operation of a collar type thrust bearing as shown at Fig. 2. Here we see that under the influence of the thrust load the faces of the collars are pressed tightly against the corresponding steps in the bushing and that if the thrust is constant it is very difficult to get oil between the surfaces in contact. As soon as the oil film existing between the surfaces is used up we have an actual metal-to-metal contact and then the friction laws apply to a dry or poorly lubricated surface rather than that ideal condition quoted by Mr. Thomas. This necessitates supplying oil under pressure that would increase and insure lubrication as the load upon the bearing augmented.

If Mr. Thomas will carefully analyze the foregoing argument he will find that his criticism of the statement was not justified in as much as he attempted to apply ideal conditions where it would be difficult to duplicate them in a practical manner. Even if the steps of a collar type thrust bearing are immersed in an oil bath the thrust pressure, if sufficiently high, will tend to break down the film of oil between the surfaces in contact and it will be difficult to introduce more oil to replace that used up. If one refers to the table presented above it will be seen that with any system of lubrication which remains the same regardless of pressure existing between surfaces enough load can be applied to cause the bearings to seize. If so much depends on securing proper lubrication the writer's contention that the lower unit pressures make for increased efficiency is founded on facts.

Considering next Mr. Thomas' criticism of method of mounting the worm, the writer desires to state that the only mountings which were recommended as giving the best results were Figs. 8 and 9 in the December issue of MOTOR TRUCK. Mr. Thomas' statement regarding the expansion of the worm under heating influence of friction is well founded and it has been demonstrated that this should be compensated for by some

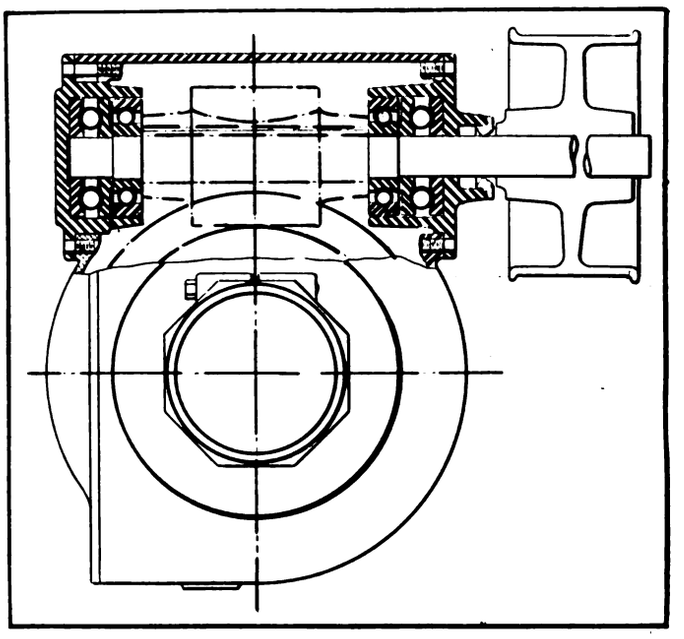


Fig. 3—Typical Design of Worm Mounting, Showing Conventional Combination of Thrust and Radial Bearings.

means. In some cases, however, the expansion due to the heating which usually obtains when properly constructed worm gearing is in operation is so slight as to be practically negligible. The mounting shown at Fig. 6 in the article previously published, which Mr. Thomas criticises, is similar to that used by a maker who has had much experience with worm drive, while that at Fig. 8 has been employed with success by the company with whom the writer is affiliated. At Fig. 3 herewith is presented a mounting taken directly from a leading engineering print and shows bearing installation in which no provision is made for worm extension.

Let us consider more closely what the actual expansion would be. Assume that we had a steel worm one foot in length and that friction would produce a rise in temperature of 200 degrees Fahrenheit, which is somewhat higher than would be desirable to have exist as it approaches the maximum degree of heat at which even perfectly lubricated bearings will run with any success. Take the co-efficient of linear expansion of steel to be .0000063 inch an inch length a degree Fahrenheit. This would indicate a total expansion of .01 inch, or about .005 inch extension each side of centre line. This condition can only exist assuming there is a difference of temperature of 200 degrees between the gear and the housing and the bearings. It is safe to assume that if there is any heating in the gearing the containing case would also rise in temperature and that the bearings and their retaining members would become hotter and expand proportionately as the worm increases in temperature; in fact, if the case were of bronze, it would expand faster than the steel worm as the co-efficient of linear expansion for that material is .0000098 inch an inch length a degree Fahrenheit.

Digitized by Google

In view of what has been demonstrated it would seem that the mounting of double row bearings described in the criticised article is not wrong and there can be but little question about their desirability. It has been shown that while worm expansion under ordinary conditions is slight it would be well to make provision for some slight degree of increase in unit length of the worm shaft. This can be done very satisfactorily by using the mounting suggested at Fig. 9. Even in the case of Fig. 8, where two double row bearings are used, one at each end of the worm shaft, it will be evident that with a maximum clearance space or "float" of .005 inch or even double that amount between the clamping nut and the bearing at each end there could not exist any play or lost motion between the bearing parts because it is a unit construction. Under this condition of mounting any increase in length due to worm expansion would be easily taken care of.

Another criticism which Mr. Thomas makes is that he cannot follow fully the line of reasoning which shows end thrust pressure lower than his guess of the load that exists on the worm teeth, which he places at the moderate (?) amount of 30,000 pounds. With reference to this the writer can only say that the formulae have been taken from standard authorities and as values are given and the equations worked out it would seem that any one could follow same without a burdensome expenditure of thought.

Mr. Thomas assures the writer that while he has had no experience with the bearings under discussion he feels that they would surely fail if selected with reference to the loads mentioned in the article. Let us see how this works out by considering some typical bearings which would be adequate to resist the end thrust loads believed to exist by the writer. Take the maximum thrust load stated or 1200 pounds which is given when the gearing is in the reverse ratio and the full horsepower of the motor minus the inevitable loss in the gears of the change speed mechanism is being delivered to the worm. If one selects a collar bearing of the ball type from standard tables to resist this load at 250 revolutions a minute, one will find it necessary to use a bearing of 1.75 inches bore, using 11 .75-inch balls and having an outside diameter of four inches. When it is realized that this bearing is suitable only to take thrust and that it must be used in connection with a single row bearing it will be seen that this makes quite a practical size. A radial bearing suitable for use in connection with the bearing mentioned would be about a No. 1309 which has a bore of 1.7716 inches (45 mm) and an outside diameter of 3.937 or 100 mm which will have adequate capacity for the maximum radial loads because two such combinations of bearings will be necessary, one at each end of the worm. It will be evident that the load rating as given by the writer is that assumed to be present when the truck is being run on the reverse ratio, a maximum value. When selecting a New Departure double row bearing it will be found desirable to use a No. 311 at least. This would have a bore of 2.1653 inches or 55 mm and an outside diameter of 4.7244 inches or 120 mm. Obviously any main drive shaft two inches in diameter will transmit 40 horsepower without much danger of rupture. Assuming that in truck work one would prefer a bearing of the heavy series, a No. 411 which has the same bore as the No. 311, but uses larger balls and which calls for a housing having a bore of 5.5118 inches or 140 mm, could be utilized to advantage. This would provide a factor of safety that would be desirable.

At the other hand let us consider the thrust load at 30,000 pounds, which Mr. Thomas evidently believes to exist, according to his own statement, and figure a bearing size to resist same by using standard formula. One will find that a collar thrust bearing about seven inches bore, 18 inches in diameter and having nine 3.5-inch diameter balls would be just about suitable to sustain 30,000 pounds at 250 revolutions a minute. When one considers that Mr. Thomas' guess regarding load is compared to that determined by the writer to exist at 1000 revolutions a minute or while the truck is in direct drive it is evident that a thrust bearing of the ball collar type adequate to resist 30,000 pounds thrust at 1000 revolutions a minute would be of such size to tax the ingenuity of a designing engineer, to install at any other point except the load carrying platform of the truck under discussion.

If Mr. Thomas prefers plain thrust bearings of the collar type, which by his own statement, have less friction and consequently longer life the more load one puts on them, he will find, assuming a maximum permissible load of 300 pounds a square inch projected bearing area, that it would take collars having an area of at least 100 square inches to resist a thrust of 30,000 pounds. Taking a typical example to show the absurdity of such a statement it would mean providing a series of five eight-inch diameter collars on a six-inch shaft.

The writer feels that a little intelligent use of pencil and paper and reference to a few formulae and tables readily accessible to any one of an inquiring nature would have saved Mr. Thomas making some statements regarding loads or friction which are founded on so little reflection that, obviously, further comment would be superfluous. The writer desires to thank Mr. Thomas for his criticisms of the article, but feels that when the article is reread with the view of securing an intelligent understanding of the statements made therein, the exceptions cannot be upheld.

I await with some degree of interest a criticism and analysis of the formula presented to show that my statement of loads existing under the conditions stated are radically wrong. In this connection it would be well to state these are only approximations and may vary by small amounts from stresses which will actually exist at the point specified. Trusting that you will find space enough to publish this somewhat lengthy exposition which should answer Mr. Thomas' criticisms fully enough so he may obtain a better understanding of the subject under discussion, I beg to remain,

Yours very truly,

VICTOR W. PAGE, M. E.

MANY CITIES ADOPT WHITE 'BUSES.

That there is a growing tendency to adopt motor propelled omnibuses is evidenced by the announcement that Indianapolis, Ind., has opened a line of machines and that a company has been formed in Kenosha, Wis., for a similar purpose. In the former city the Rapid Transit Company has placed in service several vehicles of the same type as utilized by a Chicago concern. These are the product of the White Company, Cleveland, O., and the chassis is of the 1.5-ton class. These machines seat 18 people and all are of the pay-as-you-enter type. They are fitted with electric fans for summer and a heating system is employed in the winter. The seats are luxuriously upholstered and the interior of the car is lighted by electric dome lamps.

In the accompanying illustration is presented one of the automobiles which is proving a great convenience to the residents of Meridian street, Indianapolis, over which thoroughfare the operation of street car lines is not permitted. There are many fine residences on this street and the residents are obliged either to walk or use their own vehicles. The 'buses will operate over a territory within 3.5 miles of the "circle," the centre of the city. The cash fare charged is 10 cents or four tickets for 25 cents, 10 for 50 and 21 for $1. The company behind the enterprise has ample capital and intends to establish more White cars for service in various parts of the city.

Type of White Pay-as-You-Enter Motor 'Bus Adopted by Transit Lines Established in Several Large Cities.

The Kenosha corporation, which will utilize White vehicles to supplant the service of the Kenosha Railway, has decided upon the following schedule: Ten cents for a single trip over the entire line now mapped out. Ten tickets will be sold for 75 cents and 50 for $2.50.

SPLENDID TIRE MILEAGE.

J. J. Boobar, secretary of the Terminal Taxicab Company, Washington, D. C., writes enthusiastically concerning a 34 by four-inch Republic tire, made by the Republic Rubber Company, Youngstown, O., which recently was taken from one of its cars. This shoe was fitted to a machine weighing 2800 pounds and was operated 9744 miles on the left rear wheel before being shifted to the right front wheel for 576, a total of 10,320 miles. From the time it was installed, June 24, 1910, until it was discarded, Oct. 1, 1911, it was removed only once for repairs, May 30, 1911, when an inside fabric patch was applied at a cost of $1.80. This tire cost the company less than four mills a mile of service.

SALOM BATTERY WINS.

In competition with three other makes of storage batteries a Salom, made by the Niagara Lead & Battery Company, Niagara Falls, N. Y., won out in a trial for electric lighting the 105 taxicabs of the Taxi Service Company, Boston, Mass., recently. The average time of the test for four cars on two side and meter lights, making 14 candlepower in all, was 60 hours. The contract was made with the Salom Battery Company of New England, Boston, Mass.

TRUCKS AT MILWAUKEE SHOW.

The committee in charge of the show of the Milwaukee Automobile Dealers' Association in the Auditorium, Milwaukee, Wis., Jan. 13-20, has spared no pains to make the commercial vehicle division even more attractive than that section devoted to pleasure cars. The event is in charge of F. J. Edwards as chairman of the committee, and B. J. Ruddle as manager. Among the exhibitors of business automobiles will be the following:

Buick Motor Company, American Automobile Company, Hickman-Lauson-Diener Company, Kissel-Kar Company, Curtis Automobile Company, Bates-Odenbrett Automobile Company, Packard Motor Car Company, Johnson Service Company, Orin R. Hughes, Brodesser Motor Truck Company, American Locomotive Company, Crown Commercial Car Company, McDuffee Auto Company, Stegeman Motor Car Company, B. F. Power Company, and Universal Machinery Company.

The MOTOR TRUCK
Devoted to Motor Driven Business Vehicles of All Classes.

VOL. III. PAWTUCKET, R. I., FEBRUARY, 1912 No. 2

TWO BIG SHOWS IN NEW YORK CITY.

Madison Square Garden and Grand Central Palace Displays Reveal Much Progress—Trend of Design Is Toward Accessibility, Economy of Operation and Refinement—Splendid Business Results at Both Exhibitions.

PROGRESS in motor truck construction evidently is to be a matter of strengthening those features which may be regarded more or less as standard, rather than in radical departures from established design. This applies more particularly to the mechanical details, since it seems to be settled that the working out of body problems must be along individual lines. There are a few things, concerning which designers and constructors may be expected to disagree for all time, and no doubt this difference of opinion will extend to the purchaser and user as well. Much that has been determined in the pleasure car field has been adopted and enlarged upon in the industrial transport of today. Taking the subject as a whole, it was not to be expected that the national commercial vehicle shows in New York City would disclose any great number of features which were decidedly new.

A year ago business vehicles, or freight automobiles, were called specifically to the attention of the public for the first time in a separate show. The production of this line was regarded as in its infancy at the time, and some doubt was expressed as to the wisdom of the departure. But despite the fact that the importance of this branch of the industry was somewhat under-estimated, the display in 1911 was sufficient to indicate that much progress had been made.

Main Floor of Madison Square Garden During Second Annual Exclusive Commercial Vehicle Display.

Compared with the product on view a year ago, the industry has made rapid strides during the twelvemonth. Several new vehicles were shown for the first time, some of these being manufactured by concerns which have long been associated with the pleasure car line; others were new models brought out this season by well known truck makers, while still others were absolutely new, their sponsors never having made display in either field previously. It may be stated at the outset that the mechanical construction was uniformly superior to that of 1911, greater attention having been paid to so-called minor details; matters of design, workmanship and finish. This applies to the two exhibits as a whole, and not in any individual sense.

Having special reference to the chassis: Two or three features stand out rather distinctly, as indicating the trend of design. Accessibility to the power plant, carrying with it the location of driver, may be regarded by some as of greatest importance. The fitting of a governor, thereby taking the matter of speed regulation beyond a certain point, out of the hands of the operator, evidently has been so considered by many makers. But from the standpoint of the purchaser who desires to utilize trucks in fleets, replacing his horse drawn equipment entirely, the provision for the substitution of an extra power plant has a most direct appeal. The latter feature may be regarded as the chief innovation at the shows, albeit the designs of those on display were made public some months since.

It is well known that concerns which must depend upon horses for their delivery systems or haulage work are required to keep a number of extra animals in order that there shall be no loss of efficiency because of indisposition or death. One well known department store in New York City considers it necessary to keep a ratio of seven horses in order to be certain of the use of six. This percentage may be accepted as an average, although it may be regarded as too large in some cases and too small in others. But whatever the number of extra animals, they must be fed and housed as well when not working as when employed; an ever present source of expense.

With this latest plan of the truck maker, the owner of a fleet of commercial motor vehicles simply buys an extra power plant, which can be slipped into place instead of the disabled motor within a few minutes, hardly more than it would take to change horses, and the garage attendant is free to make necessary repairs while the truck continues

Digitized by Google

its work. The advantages are obvious. There is no delay in the delivery system, and the extra horse, if it may be so termed, eats nothing—costs nothing—while it is awaiting its turn to be useful.

This is accomplished in a number of ways, as always has been true. But special reference is made here to the simplification of the removal and replacement evidenced by the latest designs of some of the makers. These methods will be described in detail in connection with the review of the various exhibits on the succeeding pages. And it may be added the feature is confined to the power plant, but includes transmission units, etc.

In the matter of motor location, opinions still continue to be divided. It is possible that the advocates of the driver over the engine have gained ground slightly. Some of the older and best known firms still retain the hood, but it is noticeable that even with these there is a tendency toward the so-called Continental method in larger sizes. The makers of the Lozier, Locomobile and Pope-Hartford, three established pleasure car concerns which have announced trucks this season, have decided upon the under-the-floor design. In its new six-ton model Knox has gone a step further and placed the driver beside the motor in the cab, after the plan adopted by Morgan, Hewitt and Garford. Another feature which may be regarded as a trend of design is the location of the operating levers. Many concerns which still retain the right hand drive for pleasure cars are producing commercial vehicles with left hand location for the driver. In some instances this means that the levers are in the centre, while in others a left hand position is provided for these as well.

Some type of governor is fitted with a large number of makes. This is a new departure, insofar as the shows are concerned, as very few manufacturers had decided upon this a year ago. Self-starting devices also are beginning to make their appearance although their use is not sufficiently general to make it appear that their need has been entirely proven. It will be surprising, however, if the number were not increased materially during the coming year, as it is known that several makers are working on devices of their own design.

Splendid Setting in New Grand Central Palace, Where Trucks Shared Interest with Pleasure Cars.

Many of the new machines present features which may be regarded as novel and distinctive. This holds true particularly of transmissions, a number of which must be considered as entirely new although they have been given sufficient test by the makers to warrant their appearance in the market. Last year, the Pierce-Arrow appeared with a worm and worm wheel drive, and the list has been increased by the addition of the Newark and Rowe, although the latter was not shown. Other minor changes will be illustrated and described herein.

All told, there were 72 different makes of commercial vehicles represented in the two displays; 35 at Madison Square Garden and 37 at the Grand Central Palace. Of the 72, 12 were operated by electricity, nine of these being shown at the Garden and three at the Palace. Two hundred and forty-two complete vehicles and chassis were displayed, divided as follows: Garden—Gasoline, 100; electric, 35. Palace—Gasoline, 95; electric, seven.

Of the gasoline vehicles and chassis displayed at the Madison Square Garden, six were equipped with single-cylinder motors, 19 with two, and 75 with four. At the Grand Central Palace, there were eight having two-cylinder, four-cycle motors; nine with two-cylinder, two-cycle; nine with three-cylinder, two-cycle, and 62 with four-cylinder, four-cycle.

In the matter of cooling, it was noticeable that in a few instances those employing air had discarded the system for water, although a number of the new vehicles had selected the air-cooled motor. None of this type was shown at the Garden, while 16 vehicles and chassis displayed air-cooled engines at the Palace. This means there were six makes thus represented.

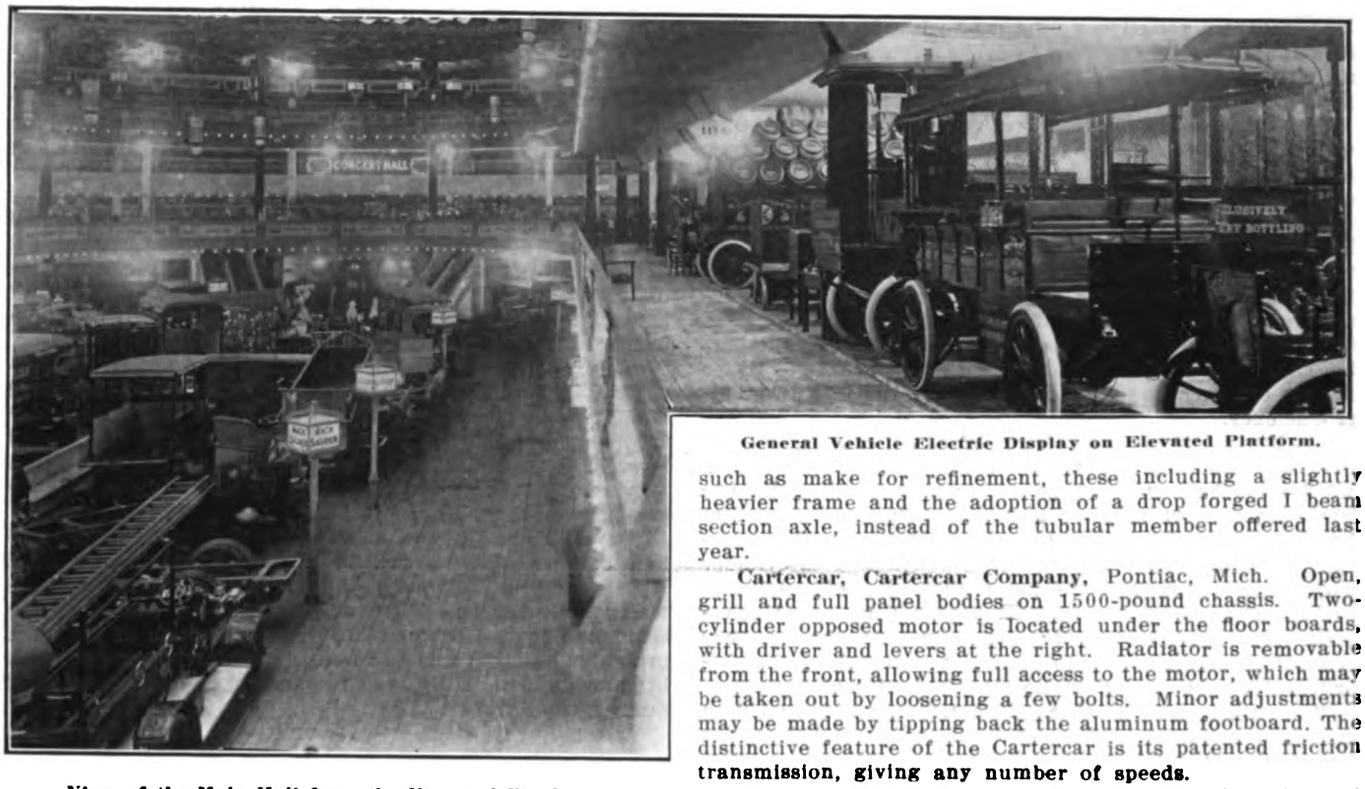
It has been mentioned herein that body designs are largely a matter of individual application. Naturally, they played a decidedly important part in the display. A visitor at the show might gain the impression at first that the industry was seeking to secure a large share of the brewery and coal business, although, of course, the delivery and general utility wagons far outnumbered the special designs. It is true, however, that brewery wagons and coal dumpers were to be seen at a number of spaces, and some really ingenious devices were included among the latter.

The succeeding pages contain a somewhat detailed description of the various exhibits, affording opportunity to discuss the new features, both in chassis and body design. Where new models were shown, it has been deemed best to include features which may not be regarded as especially new, in order that the reader may become more or less familiar with the constructional details of these products.

With respect to the attendance, it is announced that nearly 70,000 people visited the Madison Square Garden during the week devoted to the display of industrial transports. Inasmuch as commercial and pleasure vehicles were shown together at the Grand Central Palace, it is impossible to determine the exact number interested in trucks with the same degree of accuracy. Exhibitors at both displays declare that the business transacted was far ahead of that accomplished along this line a year ago.

Owing no doubt to the fact that fewer municipal service wagons were exhibited this year, there was decided decrease in the number of city officials who attended the show. Their places were taken by a largely increased list of farmers, and it was interesting to note how well informed these tillers of the soil were, when it came to discussing mechanical features of the various cars on display.

Business men in all walks of life were well represented. And with these it is stated that there was a closer investigation of mechanical construction than ever before, although most of them were deeply interested in the body problem. In nearly every case it was found that the inquirer was prepared to buy, providing he could find that which best suited his needs. More real sales and more good prospects than last year, was the chief result of the shows.



As is well known, an effort will be made in 1913 to combine all makes of commercial vehicles in one exhibit, providing a suitable building can be secured, and there is little doubt that this plan will meet with the approval of the manufacturers.

Digitized by Google

EXHIBITS AT THE MADISON SQUARE GARDEN.

WITH exactly the same decorative scheme as that which pleased thousands at the pleasure car show in Madison Square Garden, New York City, the previous week, the commercial vehicle manufacturers held their second exclusive display in that historic structure, Jan. 15-20. The event was under the auspices of the Automobile Board of Trade and the management of the following show committee: Col. George Pope, Col. Charles Clifton, Alfred Reeves and Merle L. Downs.

In the review of the exhibits below, it will be noted that the makes of machines are offered in alphabetical order, followed by the name and address of the manufacturer, and the vehicles and chassis on display. No attempt has been made to discuss the offerings of the accessory exhibitors, it being deemed best to reserve this for a succeeding issue. It may be stated, however, that there were 181 representatives of this character, all located on the upper floors, the basement being closed for the second week, and that their share of business was much more satisfactory than was true during the commercial vehicle show of 1911.

View of the Main Hall from the Elevated Platform.

Alco, American Locomotive Company, New York City and Providence, R. I. Two-ton bottled beer wagon, 3.5-ton chassis, five-ton coal dumper. In these the motor is located under the floor boards with the driver and levers at the right. Accessibility is afforded by removing two long side plates, or by lifting the floor boards. As a feature of refinement, making for economy on tires, it is pointed out that the service brake cannot lock the wheels until the speed of the truck has been reduced to two miles an hour. Governors are fitted on all models.

The two-ton chassis is claimed to be 25 per cent. lighter than previous constructions. The body shown was of all metal, and provided with entrances at the side and rear. The capacity was 72 boxes of bottled beer. The dumping body also was of metal, and arranged so as to dump at the side. The hoist was operated on two standards with a succession of gears and by hand crank.

Autocar, Autocar Company, Ardmore, Penn. Chassis, station 'bus, furniture van, casket wagon, enclosed delivery, wire grill, stake and open passenger 'bus; all of 1.5-ton capacity. The motor is under the floor, with driver at the right, and right hand levers. Accessibility is obtained by folding the seat and floor boards in an upright position. No particularly new features were disclosed, the same two-cylinder opposed motor and patented double reduction final drive being retained.

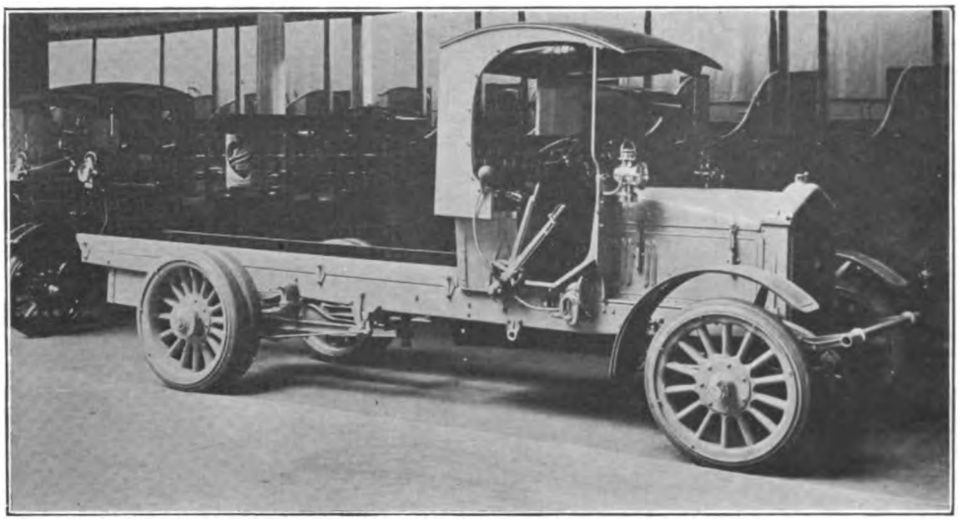
Of the body designs special attention was called to the open passenger 'bus, seating 14 besides the driver. The seats run crosswise, and enclosed doors are fitted on the right side.

Brush, Brush Runabout Company, Detroit. Seven hundred-pound chassis and two panel delivery wagons of the same capacity. Motor is in front under a hood, and driver at the left with left hand levers. No new features were presented, the single-cylinder engine with auxiliary balancing device being retained, as well as the unique spiral spring suspension.

Buick, Buick Motor Company, Flint, Mich. Eight different types of bodies on one-ton chassis. Two-cylinder opposed motor is located under the floor boards, with driver and levers at the right. The only changes are

General Vehicle Electric Display on Elevated Platform.

such as make for refinement, these including a slightly heavier frame and the adoption of a drop forged I beam section axle, instead of the tubular member offered last year.



Cartercar, Cartercar Company, Pontiac, Mich. Open, grill and full panel bodies on 1500-pound chassis. Two-cylinder opposed motor is located under the floor boards, with driver and levers at the right. Radiator is removable from the front, allowing full access to the motor, which may be taken out by loosening a few bolts. Minor adjustments may be made by tipping back the aluminum footboard. The distinctive feature of the Cartercar is its patented friction transmission, giving any number of speeds.

Flanders, E-M-F Company, Detroit. Chassis and panel delivery wagon, each of 750 pounds capacity. Motor is located in front under a hood, and the driver is at the right, with right hand levers. This may be regarded as a new product of the Studebaker Corporation, and the chassis is similar in every respect to that of the well known 20 horsepower pleasure car, except that it has been strengthened at a number of points to adapt it for light delivery work.

Garford, Garford Company, Elyria, O. Chassis, wholesale milk wagon, wholesale grocery wagon, brewery barrel wagon, all of five tons capacity, and 1.5-ton public service delivery. In the smaller vehicle the motor is located in front under a hood, but in the larger it is in the cab beside the driver. Operator is located at the right with hand levers. Radiator may be removed and the motor dismounted through the front. Minor adjustments in the larger car may be made without leaving the cab.

The five-ton Garford is an entirely new model, and the 1.5 and three-ton, the latter of which was not shown, have been changed sufficiently to make them new as well. Heretofore, Garford trucks have utilized a friction transmission, and it is understood that the older models still may be had

Digitized by Google

Worm Driven Pierce-Arrow Was a Distinctive Feature of the Show.

with this upon special order. However, the new specifications include a selective sliding gear with three speeds forward and a reverse. Drive is by jackshaft and double chains to the rear axle. Other changes have been made to correspond with the difference in transmission.

G. M. C., General Motors Truck Company, Detroit. One, two and three-ton stake, two-ton delivery, 3.5-ton chassis and furniture van, and five-ton brewery wagon. This line really is a combination of the old Reliance and Rapid, both of which retain their essential characteristics, although the design has been modified slightly. The models heretofore known as Reliance are made in the two, 3.5 and five-ton sizes, and the motor is mounted on a sub-frame attached at three points to the main chassis frame. The Rapid is continued as one, two and three-ton vehicles, minus the chain cases and equipped with a governor. Other changes are such as are intended to give the machines better efficiency.

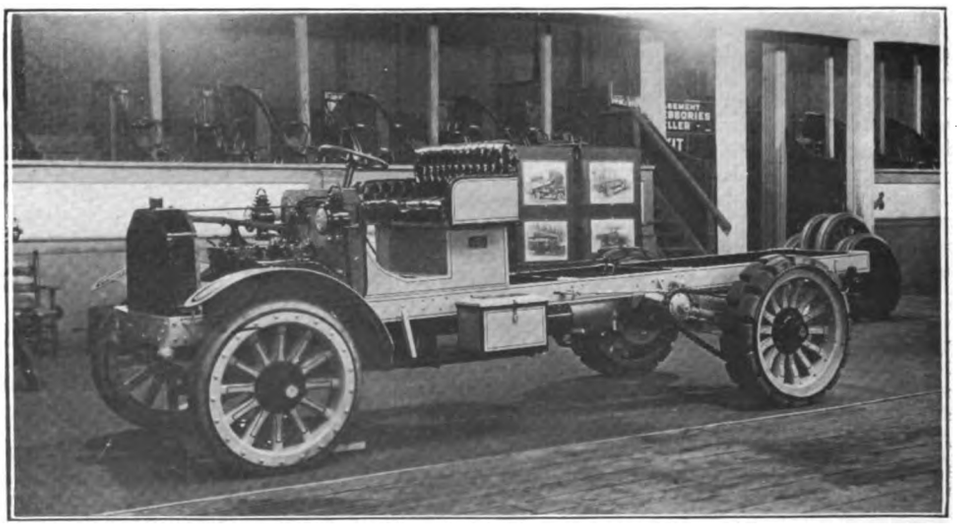
Grabowsky, Grabowsky Power Wagon Company, Detroit. One-ton piano wagon, three-ton chassis and furniture van, and five-ton brewery wagon. Motor is partially under the floor with a short radiator in front. Driver is located at the right with right hand levers. Several changes in design are noted, among them being the new four-cylinder vertical motor, replacing the two-cylinder opposed engine of former years, and the substitution of a three-speed selectively operated gearset for the planetary change gear mechanism. Other features include a governor of the butterfly valve type in the intake manifold and self-starter.

The motor, transmission and clutch are mounted as a unit on a sub-frame, which is removable bodily from the chassis through the front. The short hood is hinged at the top, and the front cross bar at the left. These being opened, the power plant unit is so arranged that it slides in and out like a drawer. A wooden horse, on which is mounted a pair of rails registering with those carrying the motor in the chassis, is rolled into place and the work of removal thus becomes a most simple matter.

Hewitt, Hewitt Motor Company, New York City. Three chassis, of one, 3.5 and 10 tons capacity, respectively, and seven-ton brewery wagon. Motor is either under the floor or beside the driver in the cab, and the operator is placed either at the right or left with levers, accordingly. Several other models are made but not shown. Some retain the two-cylinder opposed motor; some are supplied with selective sliding gear transmission and others with the planetary type.

As was true at last year's show, the 10-ton Hewitt was the largest vehicle on display. This is one of the models with a planetary gearbox. The chassis was shown beside that of the one-ton, still further accentuating its size. The entire line offers little that is new in mechanical construction, it being claimed that the various features have proven decidedly satisfactory in service for a number of years.

Knox, Knox Automobile Company, Springfield, Mass. Two-ton delivery wagon, five-ton wholesale fruit wagon, six-ton chassis, gasoline driven pumping engine. Motor is located under the floor in the two smaller sized trucks, while in the six-ton vehicle it is beside the driver in the cab. Operator and levers are at the right.



The six-ton machine is a new model, although it does not differ materially from the five, except in the heavier construction. The principal distinguishing feature is the location of the motor in the cab, following the practise adopted by Garford, Hewitt and Morgan. Governors are fitted to all models this year.

The pumping engine, which was seen for the first time at the 1911 show, has been changed slightly, as subsequent tests have revealed the desirability. The pump is of the double-acting two-piston type, and the single chain drive of last year has been replaced by two chains. The motor is a six-cylinder unit, rated at 60 horsepower. The pumping capacity is 600 gallons of water a minute.

Locomobile, Locomobile Company of America, Bridgeport, Conn. Five-ton chassis, and combination chemical and hose wagon. In the truck, the motor is placed under the floor boards, with driver at the right and right hand levers. Accessibility is afforded by tilting the seat backward, and minor adjustments may be made by the removal of side panels.

Inasmuch as this is an entirely new model, produced by a concern which is well known in the pleasure car field, it will prove of interest to give a brief description of its mechanical details. First, it ought to be said that the company does not contemplate the construction of bodies at present, although it is understood that arrangements have been made with a Bridgeport concern to do this work if desired.

The motor is a four-cylinder unit, with bore of five inches

Peerless Line Was Represented by One Five-Ton Chassis Only.

Digitized by Google

and stroke of six, water-cooled and rated at 45 horsepower at 900 revolutions, to which speed it is restricted by a governor of the vertical ring type. The crankcase is of bronze; the valves are large and equipped with quiet valve lifters, and the crankshaft is of alloy steel carried on five large bearings.

The carburetor is of the float feed type with single jet, a Locomobile design. Mixture is controlled from the seat. Ignition is by high-tension magneto and storage battery. Cooling is by means of a honeycomb radiator with gear driven centrifugal pump, the former being protected by channel cross members and supported on one-inch rubber blocks. Lubrication is by a self-contained system for the motor, a gear driven pump forcing oil to all bearings in a constant stream. Grease cups are fitted at all wearing points on the chassis.

The transmission is a four-speed selective type with a bronze gearcase. Clutch is of the dry disc type; 14 special steel discs, seven of them being lined on both sides with non-burn material. Drive is by double chain. Springs are semi-elliptical, 42 inches long in front and 50 in the rear. The latter are shackled at both ends. A transverse jack spring is fitted to absorb all road shocks.

Front axle is a solid forging of the I beam section, and pivots have roller thrust bearings to reduce friction. The rear member is a rectangular section forging of alloy steel. Emergency brakes expand on sprocket drum bolted to the rear axle and the service members contract on a drum on the jackshaft to which front sprockets are bolted. Wheels are of cast steel, 40 inches in diameter, with roller bearings front and rear. Wheelbase is 140 inches, tires 40 by six inches, single in front and dual in rear.

The fire wagon shown did not differ materially from those which have been displayed by this concern previously. A slightly longer wheelbase and a special form of rear axle, somewhat heavier in construction, were the principal features noted.

Lozier, Lozier Motor Company, Detroit. Five-ton chassis. Motor is located under the floor boards, with driver and levers at the right. Motor, transmission and driver's seat are mounted on a sub-frame, which is supported by springs, independently of the frame and springs of the chassis itself. Accessibility is afforded by lifting the floor boards and turning the seat out of the way, or these may be entirely removed and the power plant exposed for thorough inspection. The sub-frame is hinged at the rear end to a cross frame member, while the forward end rests on independent auxiliary springs. The removal of four bolts in front and two in the rear enables the entire power plant, consisting of motor, cooler, clutch, transmission, steering wheel and driver's seat, to be taken from the chassis.

This also is a new model, produced by a well known pleasure car maker. The four-cylinder motor has a bore of 4.25 inches and stroke of 6.5, water-cooled, and rated at 35 horsepower at 900 revolutions, maximum torque being developed at this speed. The cylinders are offset, and the crankshaft mounted on annular ball bearings. Valves are of nickel alloy, and are all located on one side. Camshafts are driven by silent chains in an oil tight case, following the latest European practise.

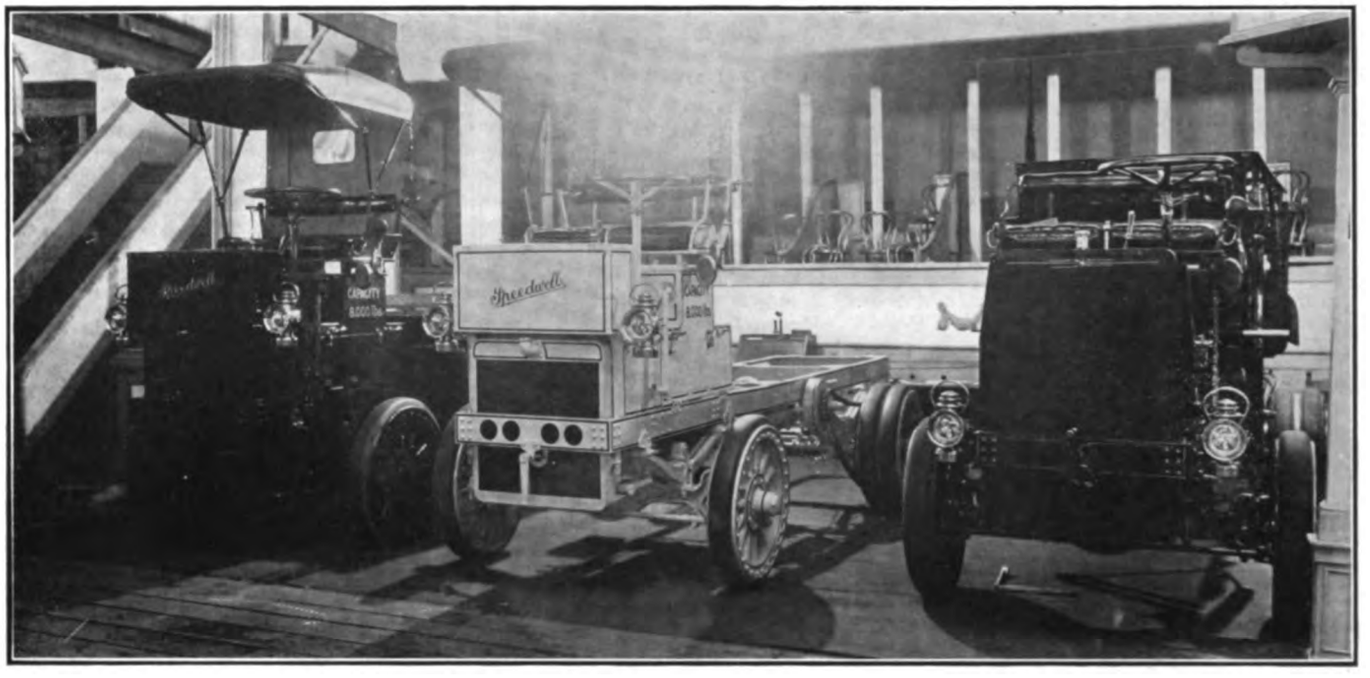
A governor operated on a valve in the inlet manifold separate from the carburetor, permits the operator to remove the vaporizer without disturbing the governing mechanism. Carburetion is by a Lozier device located on the left side, while ignition is by Bosch magneto, placed on the right, and storage battery.

Lubrication is a combination of splash and force feed, the splash level being adjustable from the front end of the motor case. Oil is taken from the bottom of the crankcase by a gear driven pump and distributed to the bearings and splash pockets, overflowing into the oil cellar through a strainer.

The transmission and jackshaft are made up of two separate units, the former being of the selective sliding gear type, with four speeds forward and reverse. Clutch is of the standard Lozier design with 28 hardened saw blade steel discs enclosed in an oil tight flywheel case. Power is transmitted from the clutch to the transmission through a double universal joint of the block type, made of high carbon steel, hardened and ground, and enclosed in a metallic dust proof oil case.

Service brakes are mounted on the jackshaft and are of the contracting band type, 14 inches in diameter by 2.5 in width. Emergency members are of the internal expanding type enclosed in the rear wheel drum, 18 inches in diameter and with four-inch faces. The wheelbase is 134 inches. The centre of gravity is forward of the rear axle, increasing the load on the front wheels as the truck load is increased.

Front and rear axles are drop forgings from high carbon, heat treated, open hearth steel, and of rectangular section. On the front members the spring pads are carried below the centre of the wheel, the axle having a drop of five inches, allowing the lower half of the motor case to be removed without interfering with the axle. This also permits the engine to be placed sufficiently low in the subframe to give practically a straight line drive.



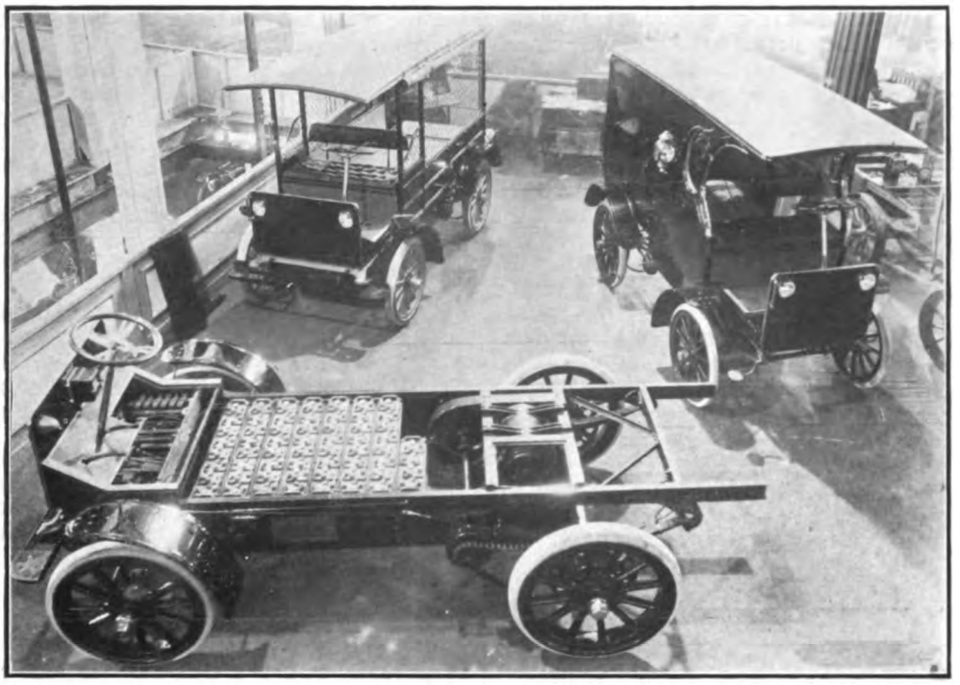


Exhibit of Speedwell Trucks Occupied a Prominent Position Underneath the Elevated Platform on the Main Floor.

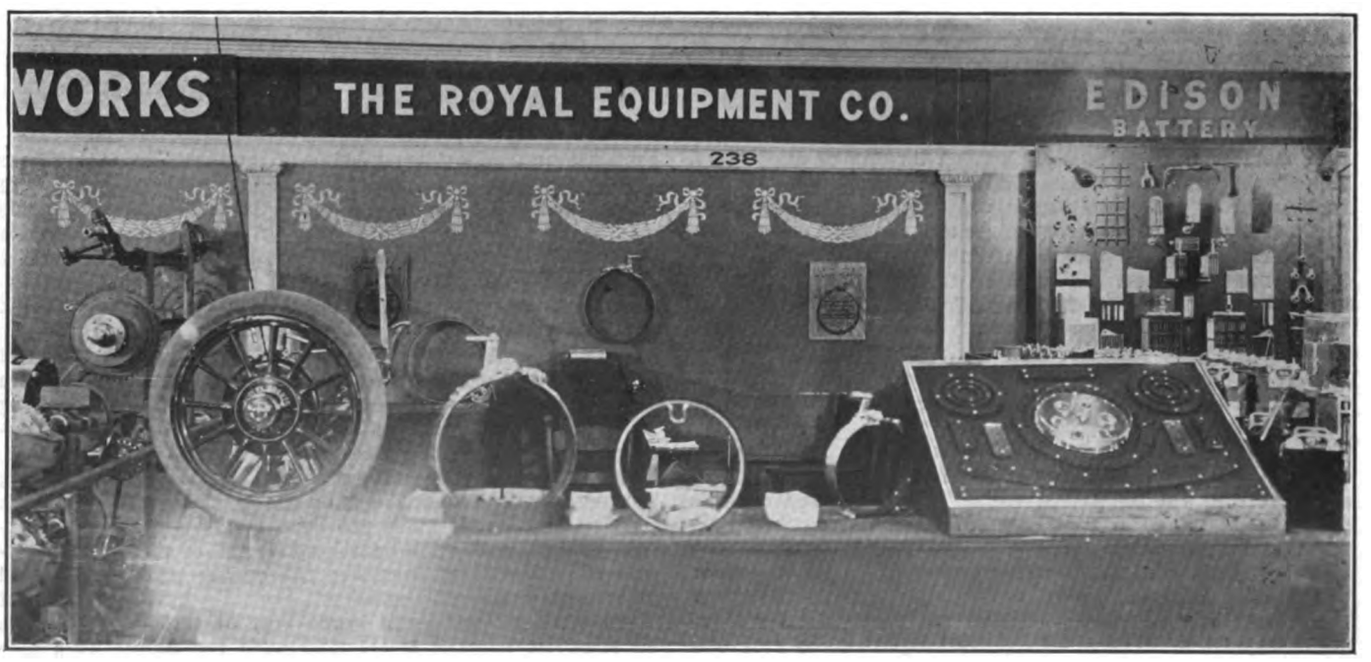
Digitized by Google

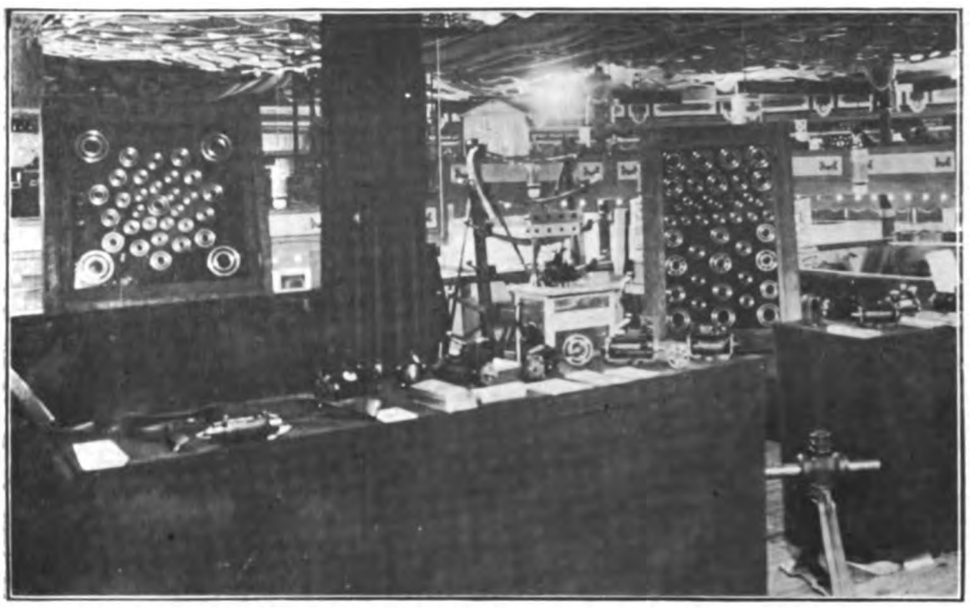
Detroit Electric Line Was Shown on the Elevated Platform.



Springs are semi-elliptic in front and platform in rear. Wheels are of the artillery type, and are equipped with 36 by five-inch front and 40 by five-inch rear, standard S. A. E., demountable tires, dual behind.

Mack, International Motor Company, New York City. One-ton chassis, 1.5-ton army water filter wagon, three-ton telephone service wagon with winch, five-ton brewery wagon and seven-ton coal dumper. Motor is located in front, with driver and levers at the right. This portion of the International Motor Company's exhibit is made in the Mack works at Allentown, Penn. The chassis details offer very little change from the Mack trucks of previous years, the special features of the exhibit being the novel body designs.

The subject of dumping bodies appears to be receiving merited consideration by a number of makers, and the seven-ton coal dumper at this space was a centre of much interest throughout the week. The hoisting device is mounted on special braces fitted to the back of the cab, and the mechanism is operated by means of a transverse shaft directly beneath and in the same plane as the upper cross shaft. This is driven from a small countershaft, situated in the transmission, by means of a worm and worm wheel, and this small shaft is in turn operated by a sliding spur gear, which meshes with the second speed gear on the main transmission countershaft, when the hoist is to be used. When the sliding spur gear is thrown into mesh, the driving dog for the main countershaft gear is thrown out, which makes it impossible to move the vehicle while the body is being raised. The latter, however, can be stopped in any position, and the truck driven over the road without the body being drawn back to its original position.



Driving into position for dumping, the operator moves the small hand lever at the right of the seat forward and downward, bringing a sliding gear into mesh with the second speed gear and at the same time disengaging the intermediate gear clutch. The gear shifting hand lever will be moved into the second speed, and the clutch let in, when the body immediately will begin to ascend. When in its extreme upward position, the clutch automatically is thrown out by means of a stop on the hoisting chain, which prevents the lifting arm being drawn over centre.

To lower: The reverse is engaged, and the clutch let in, when the body begins its descent. As before, the clutch automatically is thrown out, just before the body reaches the frame, which prevents the former coming down hard upon the latter. The small hand lever is pulled back into position and the driver is free to resume his journey for another load. The whole operation takes about 20 seconds. In the device shown the tail gate was operated automatically, although it is possible to obtain this for hand operation if desired. With the equipment as displayed, it is possible to unload the entire contents of the vehicle without leaving the seat, simply by moving the hand levers and depressing the clutch pedal.

Important Display of Duplex Brakes and Other Equipment, Made by Royal Equipment Company, Beside Edison Storage Battery Exhibit.

Digitized by Google

Marburg Bros., Inc., Displayed Mea Magnetos and Other Products.

The water filter is a device patented by Osborn Congleton, for which the International Motor Company has secured the rights of manufacture. It is claimed that by its use, 500 to 1500 gallons of pure water an hour can be supplied, five minutes after the camp is pitched beside any stream. The master faucet controls the pump, which is operated by the motor. The water is drawn up through a series of filters, in which a variety of filtering materials is employed for the removal of bacteria and other impurities.

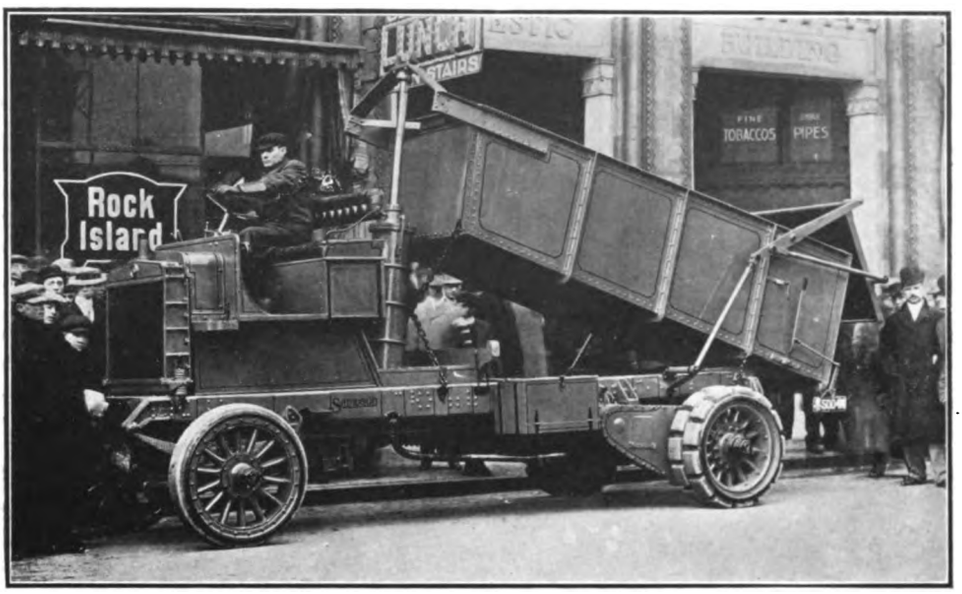
Martin Tractor, Knox Automobile Company, Springfield, Mass. One complete tractor mounted on a new Knox six-ton truck. Although originally designed to be supplied with three wheels and still marketed as such, the present arrangement is with one wheel in front and suitable mechanism in the rear for attaching to the king bolt of any horse drawn vehicle. The motor is a regulation Knox unit. A more complete description with suggestions for its use will be found elsewhere in this issue.

McIntyre, W. H. McIntyre Company, Auburn, Ind. One-ton delivery, 1.5-ton chassis and 1.5-ton mattress car with extra high top. Motor is located in front, under a hood, with driver and levers at the right. A notable change is is in the substitution of a four-cylinder vertical engine for the old two-cylinder opposed unit. The enclosed planetary transmission is another feature, and the service brake has been taken from the rear wheels and placed on the jackshaft. In other respects, the line has not been changed materially, and the governor is retained on all models.

Morgan, Morgan Motor Truck Company, Worcester, Mass. Two-ton express, three-ton chassis and five-ton coal dumper. Motor is placed in the cab beside the seat, with right hand levers and driver's position. Few changes in mechanical construction are noted, the same steel wheels, rubber cushioned jackshaft, etc., being retained. The addition of brake equalizers, auxiliary rear springs and a slightly heavier radius rod practically complete the list. The two-ton chassis is a new model, with the same essential Morgan characteristics.

The coal dumper proved of decided interest. Strictly speaking, it is not a dumper in the usually accepted use of the term. The body and load remain stationary, the coal being discharged through a metal chute by means of an Archimedian screw. Power to operate this is conveyed from the motor through a change gear mechanism, in which an extra gear and a shaft lead to a chain wheel mounted on the side of the chassis. A much larger wheel is mounted on the end of the conveyer shaft opposite to that on which the chute is attached to which it is fastened by a key. The withdrawal of this key permits the chain and wheels to rotate idly while the truck is being driven. When the load is drawn into position, the operator slips the key into place, when the motor turns the screw and the coal is forced out through the chute.

Packard, Packard Motor Car Company, Detroit, Mich. Two-ton stake body, and transcontinental prairie schooner, dairy wagon, cased beer wagon, van, gas crane, and slatted and gate sided body, all on three-ton chassis. Motor is in front under a hood, and driver is at the right with right hand levers. The two-ton model is new, being identical with the larger chassis, except for its lighter construction and its Packard 18 horsepower motor. The addition of an automatic spark retarding lever, for use in connection with starting, appears to be the only change of note.



Peerless, Peerless Motor Car Company, Cleveland, O. One five-ton chassis. Motor is located in front under a hood, with driver and levers at the right. The design has proven so satisfactory under every kind of service during the past year that only such changes as make for refinement of detail are noted. Maximum speed of the motor is limited by the action of a centrifugal governor on butterfly valve, located in the intake manifold between the throttle and cylinders. Governor adjustments are enclosed in a housing, which is sealed. A shutter interposed between the jaws of the starting crank and crankshaft prevents cranking the motor until the spark has been retarded.

Pierce-Arrow, Pierce-Arrow Motor Car Company, Buffalo, N. Y. Five-ton chassis, coal dumper and brewery service wagon. Motor is in front under a hood, with driver and levers at the right. The principal feature of the Pierce-Arrow truck is the worm and worm wheel drive, which was

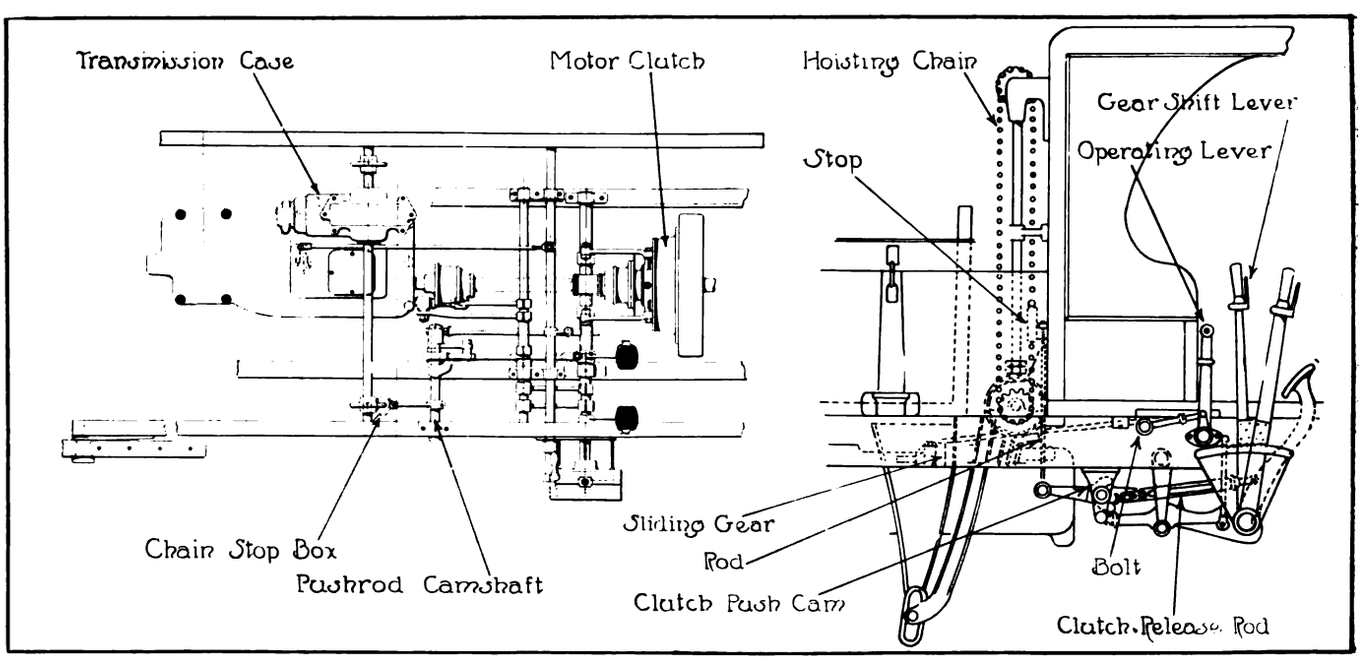
Splendid Exhibit of Ball Bearings Made by New Departure Company.

Digitized by Google

Pneumatic Dumping Device Displayed at the Sampson Exhibit.

brought out last year. One of these assemblies, with the housing partially cut away, was presented for inspection and the attendants were extremely busy explaining its method of operation. As positive proof that the arrangement is completely reversible, opportunity was afforded for those who wished to make the worm drive the wheel, or the wheel the worm, with equal ease and smoothness of action. In all respects, it was announced that the 1912 model is exactly the same as the 1911. The dumping body is operated by hand winch.

Pope-Hartford, Pope Manufacturing Company, Hartford, Conn. Two three-ton service wagons, and combination chemical and hose wagon. Motor is located under the floor, with driver at the left and levers in the centre. Accessibility is afforded by tipping the seat backward, or the seat and floor boards together. This is the first time this well known pleasure car maker has exhibited a truck, although the first vehicles of this type were produced in the early summer.



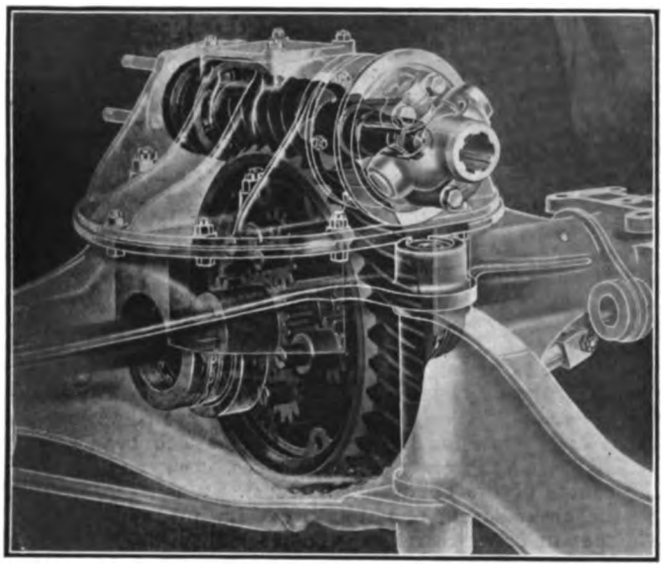
The motor is a four-cylinder, water-cooled unit, rated at 40 horsepower, the maximum speed being regulated by a governor operating entirely independent of either hand or foot throttle. Ignition is by Bosch high-tension magneto, dual system. Lubrication of the motor is by a mechanical oiler on the crankcase with a large suction pump and standpipe, which is used as an overflow, permitting oil when it reaches the level of the standpipe to run back through it into the crankcase. The crankcase proper is provided with standpipes, fitted with gauze strainers, serving to maintain at all times a predetermined level in the case. Oil is pumped from the oiler to the cylinders. The main bearings are lubricated by splash from the crankcase. The transmission and differential also are lubricated by splash. All other parts are provided with oil or grease cups wherever necessary.

The cone clutch is leather faced with cork inserts. The transmission is of the selective sliding type with three speeds forward and reverse. Drive is by double side chain. Springs are semi-elliptic, 44 inches in front and 50 in the rear. An auxiliary cross spring over the rear axle provides for overload. Wheelbase is 126 inches. Wheels are 36 inches, demountable, fitted with Timken roller bearings. The front axle is a solid I beam section, the rear member a solid forging.

Three sets of brakes are fitted; contracting bands on each end of the jackshaft, 12.4375 inches in diameter and 2.25-inch face; contracting band on transmission shaft, the same size, and emergency, internal expanding band on rear wheels, 18 inches in diameter with three-inch face. Tires are 36 by five inches, single front and 36 by four, dual in rear.

Very little change was noted in the fire apparatus, this concern having given its attention to the construction of these vehicles for some years.

Reo, Reo Motor Truck Company, Lansing, Mich. Three 1500-pound delivery wagons. Single-cylinder motor is located underneath the chassis. Driver is at the left with left hand levers. Practically the only change in design over that shown for the first time a year ago, is in the fitting of mudguards. The Reo has demonstrated its efficiency as a satisfactory solution of the light delivery problem under every condition to which it has been applied, and there appears to be little reason in the mind of the designer, R. E. Olds, for changing its mechanical construction.



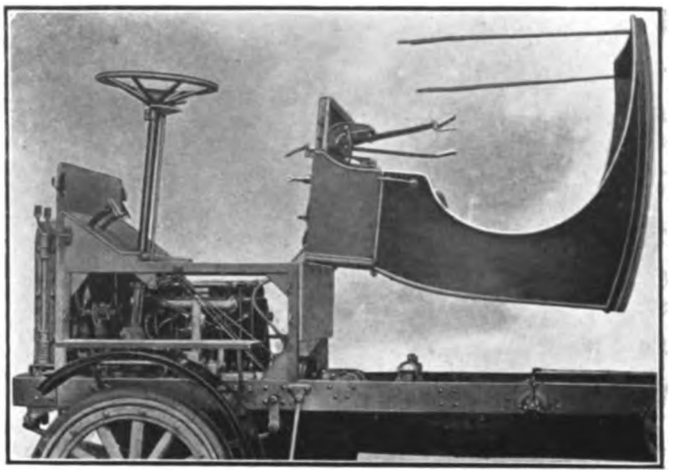
Sketch Outlining Features of the New Self-Dumping Body on the Mack Truck, Operated by the Motor Without Leaving Seat.

Digitized by Google

Sampson, Alden Sampson Manufacturing Company, Detroit. One 1.5-ton chassis, 1.5-ton delivery, 1000-pound delivery, three-ton stake body and five-ton coal dumper. In the smaller vehicles the motor is in front under a hood, but with the larger it is under the floor boards. Driver is at either the right or left, with levers placed accordingly. Practically no change has been made in mechanical construction, except the coal dumper shown, on which the 42-inch rear wheels have been replaced with 36-inch members.

The dumping arrangement is decidedly new, a cylinder behind the driver's seat serving to raise and lower the carrying receptacle by means of compressed air. This air is stored under pressure of 100 pounds in a tank on the rear end of the chassis frame, a single-cylinder pump being operated from the change gear mechanism. This compressor may be connected directly to the pneumatic hoist, in case the storage tank should become punctured or the air line should develop a leak. A Westinghouse brake, operated from the seat, controls the admission of air to the cylinder. The end gate is so arranged as to open automatically, so that the entire operation of dumping the load may be performed without the driver leaving his seat.

Saurer, International Motor Company, New York City. One 6.5-ton chassis and imported pumping engine. The Saurer is manufactured at the plant in Plainfield, N. J.,



Skeleton View of Pierce-Arrow Worm and Worm Wheel.

and the new fire equipment also will be produced in America. The special features of the truck are retained, these being the novel type of carburetor with two nozzles, compressed air self-starter and so-called motor brake. As is more or less well known, this latter embraces a hand throttle lever on the steering wheel interconnected with the camshaft, which is so arranged that the timing of the valves can be changed to permit the motor to exert its maximum retarding effort.

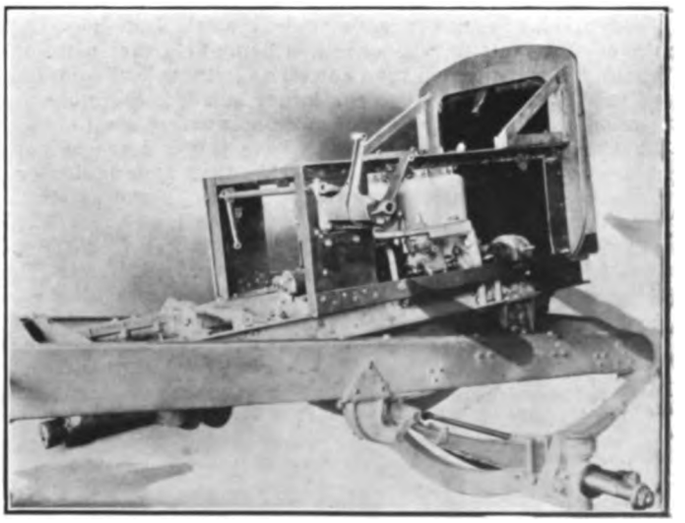
The pumping engine is equipped with a 60 horsepower four-cylinder, four-cycle, water-cooled motor, which may be coupled to a centrifugal pump, capable of delivering 500 gallons of water a minute at 100 pounds pressure. The latter utilizes the Sulzer patented self-priming feature, which has given excellent satisfaction in service abroad.

Speedwell, Speedwell Motor Car Company, Dayton, O. Four-ton chassis, four-ton stake body and six-ton coal dumper. Motor is located under the seat, with driver and levers at the right. Accessibility is afforded by tilting the seat to the side, an exceedingly novel arrangement, which is expected to meet with decided favor. Mechanical changes are not numerous, the most important being the addition of a differential lock and an automatic advance magneto.

In the coal wagon, the dumping is effected by means of a motor operated rack and pinion mechanism, which takes its motion through double reduction gearing from the propeller shaft. Provision is made for depositing the

Tilting Seat Exposing Power Plant on New Pope-Hartford.

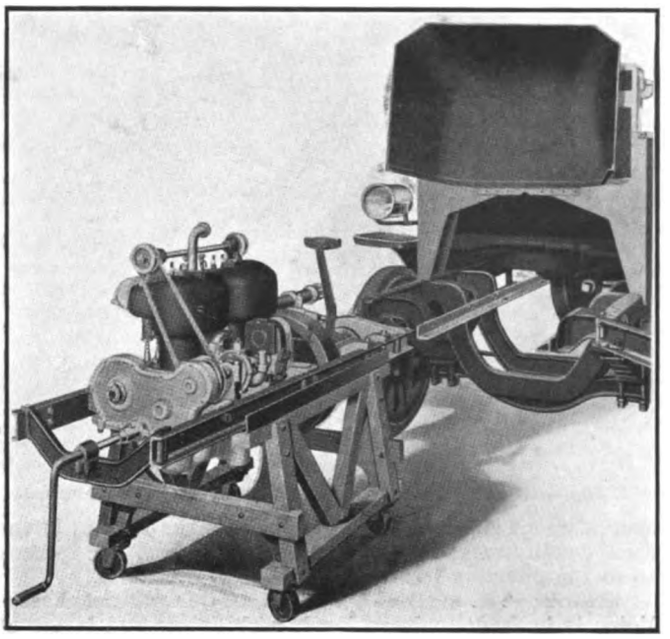
load at either side or the rear, so as to make the use of the truck equally valuable, whether or not it is possible to back up to the dumping location.



Stearns, F. B. Stearns, Cleveland, O. One five-ton chassis. Motor is in front under a hood, with driver and levers at the left. Engine and transmission are mounted on a subframe, which is carried by semi-elliptic springs on the main chassis frame. Practically the only change is the adoption of the left hand control, although the addition of a differential lock operated by means of a lever on the gear shift quadrant may be mentioned as well.

White, White Company, Cleveland, O. Fifteen hundred-pound delivery wagon, 1.5-ton 'bus, three-ton moving van, five-ton Standard Oil tank wagon and five-ton lumber body with trailer. Motor is in front under a hood, with driver either at the right or left with levers accordingly. The five-ton vehicle is an entirely new model, although its mechanical features do not differ materially from the three-ton machine, which has been the largest size manufactured by this concern heretofore.

Considerable interest attached to the lumber equipment with its trailer. These were loaded with heavy timbers, such as are used in subway construction in New York City. The trailer is a high two-wheeled device, shod with steel tires and equipped with brakes operated by lever from the driver's seat. It is attached to the main truck by means of chains. The forward portion of the outfit is designed for lumber work, independently of the trailer, and is fitted with rollers which assist in loading and unloading.



ELECTRIC COMMERCIAL VEHICLES.

Baker, Baker Motor Vehicle Company, Cleveland, O. Half-ton delivery, two-ton chassis and two-ton express body

Method of Mounting Motor in the New Losier Truck.

Digitized by Google

Illustrating Accessibility of Grabowsky Power Plant.

with screen sides. Minor changes have been made in all models, and the larger chassis has been redesigned to conform with the smaller. Emergency brakes, mounted on the countershaft, have been added, and all bearings are now bronze bushed. Sprockets are reversible, so that when the teeth are worn on on side they may be turned. Controllers are enclosed this year.

Bronx, Bronx Electric Vehicle Company, New York City. Half-ton chassis, half-ton delivery wagon and four-ton chassis. This is an entirely new line, and includes machines in varying capacities from 800 pounds to five tons.

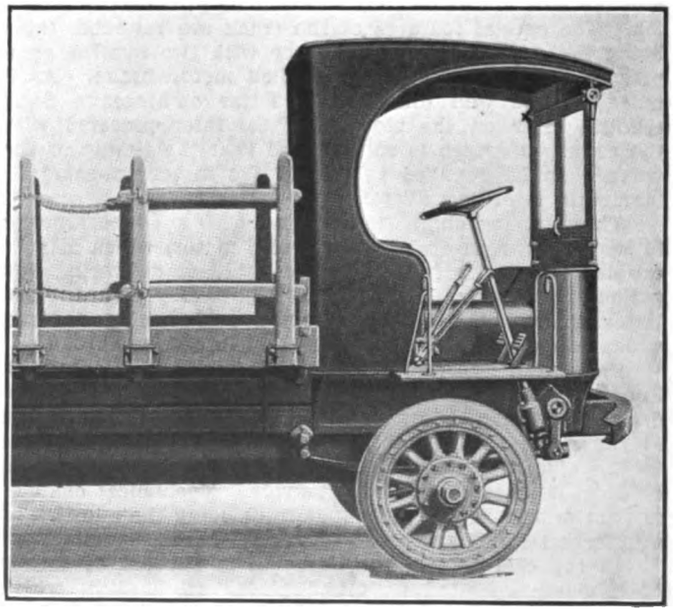
Motors are of the General Electric make, nothing less than 80-volt with 60-cell Edison battery or 32-cell lead battery on smaller models, and 85-volt with 44-cell lead battery, except when Edison is preferred, on the larger. All motor armatures run on ball bearings, in fact these are fitted wherever possible, the maker calling the product the ball bearing Bronx.

The first reduction is by quiet chain drive to the countershaft, housed in an aluminum casing, the chain running in oil. The second is by roller chain from the countershaft to rear wheels. All sprockets are of ample size, accurately cut from high grade steel. The steering gear is of the irreversible type with ball thrust bearings, rigidly mounted on chassis. Two sets of brakes are operated independently. All hubs are fitted with ball bearings, non-adjustable, it being claimed that these reduce friction to the greatest possible degree.

A special feature is made of the straight line drive from the countershaft to rear wheels, it being held that noise and chain "slapping" have been entirely eliminated. Frames are of pressed steel, except in the larger models, where channel section is used. Springs are of silico-manganese steel bushed. Shackle bolts are hardened and have integral grease cups. Axles are of nickel-vanadium steel, either rectangular or I beam section. The tire equipment is said to be well within the tire manufacturer's requirements for the load the vehicles are designed to carry.

Detroit, Anderson Electric Car Company, Detroit. One 1.5-ton chassis, half-ton panel body, one-ton screen side delivery. As is well known, the maker claims this machine has been built around the Edison battery. Few changes in chassis design have been found necessary, although the 1.5-ton model is new, with the same general characteristics which have distinguished the older members of the line. It is understood that two other sizes, a two and a three-ton, will be placed in the market in the near future.

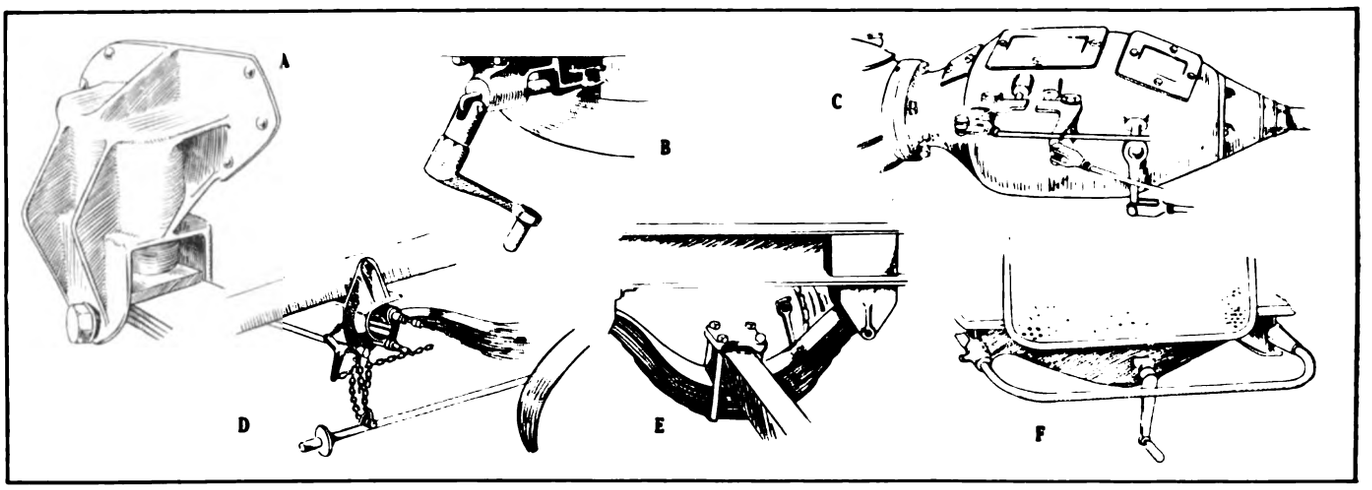
G. M. C., General Motors Truck Company, Detroit. Three ton chassis, 1.5-ton delivery, six-ton express and English coach. This is a new line, although the design is by John M. Lansden, who has been engaged in the design and manufacture of electric commercial vehicles for the past eight years. It follows that he has incorporated a number of features which have been successful in service, and as a whole the line is in no way experimental, although offered to the public for the first time.



Complete accessibility is one of the distinguishing features claimed. The motor is of the single enclosed type, specially wound for maximum efficiency with the control and battery characteristics. The battery, either lead or Edison as specified, is located above the frame, and the controller is under a small hood in front of the dash. Five speeds forward and two reverse are obtained by a handle above and eccentric with the steering wheel.

The frame is of steel, channel section, with iron faced wood bumper in front. The drive shaft is of the Lansden type, a flat spring tempered steel blade, flexible and self-aligning. Countershaft is of the floating type, with non-adjustable ball bearings. Springs are semi-elliptic, both front and rear, with auxiliary helical members on the rear axle to take care of abnormal loads and road shock. Axles are solid forgings, front and rear, the steering knuckles being with electrically welded steering arms. Wheels are of wood of standard S. A. E. dimensions, Lansden dual members being employed for dual tires in the rear.

The six-ton chassis was the largest electric vehicle in the show, but chief interest in the exhibit centred around the English coach, which is built to accommodate 12 on the inside, one beside the driver and four on top. Entrance to the interior is by side doors.



General Vehicle, General Vehicle Company, Long Island City, N. Y. One 750-pound delivery, 1000-pound delivery, two-ton American express wagon, 3.5-ton brewery bottling wagon, five-ton chassis, two five-ton keg trucks, five-ton bottling wagon, and one-ton industrial pier truck. The last named is a new model, and of especial interest. The remainder of the line is offered with practically no change, the remarkable success of General Vehicle wagons under all conditions of service having demonstrated that the detail construction is correct.

The pier truck is a low wheeled vehicle with platform in front for the driver to stand upon. Steering is accomplished with the rear wheels while the drive is through the front members. The controlling devices are somewhat unusual and correspondingly interesting. The brake pedal, which has a long crosswise foot piece, occupies a place in the centre of the operating platform. When this pedal is up the brake is on, and it is necessary to depress it with the foot in order to release the mechanism. The steering control is by means of a lever at the left hand side, having vertical motion only, and a corresponding lever on the oppo-

Location of Motor in the Cab on Five-Ton Garford.

Some Mechanical Features Seen at the Garden: A, Sampson Supplementary Spring; B, Peerless Starting Crank Support; C, McIntyre Enclosed Planetary Gearset; D, Sprag on Locomobile; E, Hewitt Rear Spring; F, White Tubular Bumper.

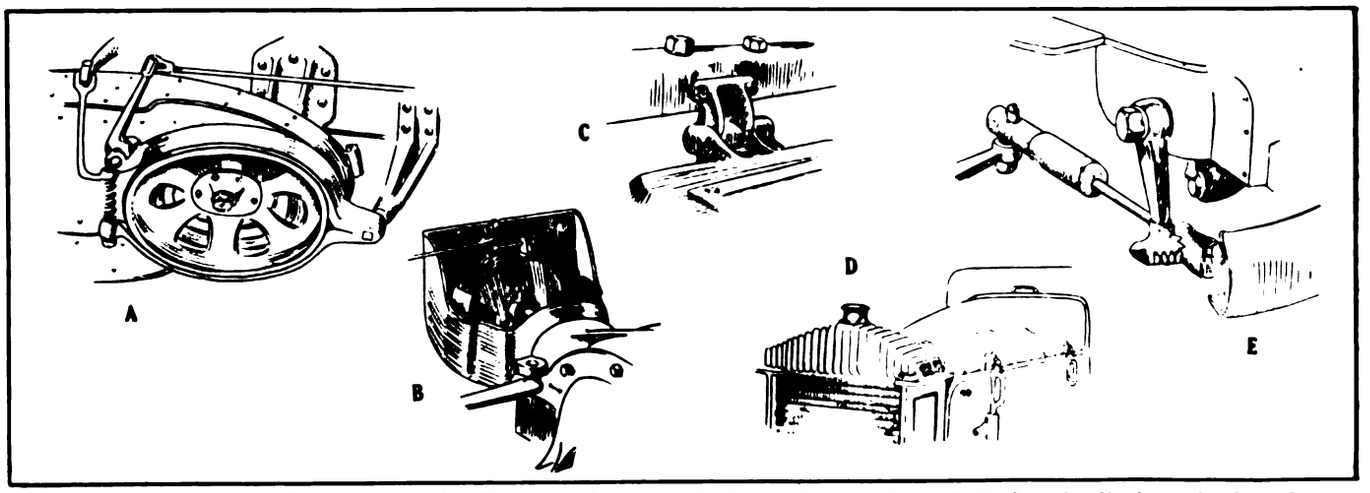
site side operates the controller. The battery is sufficient to run vehicle 20 miles on a single charge, and is suspended in a cradle at the front.

Lansden, Lansden Company, Newark, N. J. Chassis, panel delivery and provision wagon, all of one-ton capacity. This practically is a new line, having been redesigned throughout. Comparatively shorter chains are used for final drive, and silent chains have replaced the roller members between motor and jackshaft. Frames are of steel instead of wood. A new suspension carries the motor from a single cross member instead of from two. Sprockets are keyed and tapered on instead of pinned. Timken roller bearings take the place of bronze, and the controller is of the open type instead of closed. A new method of attachment makes it possible to remove and replace the wheels readily.

Studebaker, Studebaker Corporation, South Bend, Ind. One 1000-pound panel delivery wagon. The line practically is unchanged, standard features having been demonstrated as satisfactory under severe usage in various classes of service. The vehicle shown has been made a trifle lighter in some respects and now uses Timken roller bearings. New battery equipment is said to give 15 per cent. greater mileage than was possible under old conditions.

Ward, Ward Motor Vehicle Company, New York City. Three delivery wagons of 700, 1000 and 1500 pounds, respectively. No new models have been added, and only slight changes mark the line. The old style plain bearings have been replaced by Timken roller members, and iron clad batteries are used instead of the grid plate style formerly employed.

Waverley, Waverley Company, Indianapolis, Ind. Half-ton delivery, one-ton delivery, 2500-pound chassis, three-ton chassis, and central station trouble wagon. The half-ton model is new, and employs a shaft drive instead of the usual Waverley chain. The battery is an Edison. In all other respects, it follows the essential Waverley characteristics. The trouble wagon practically is a remodelled pleasure vehicle, providing space for such tools and materials as would be needed in this work.



LANGE COMPANY TO MAKE TRUCKS.

The H. Lange Wagon Works, Pittsburg, Penn., maker of wagons for over 40 years, announces the organization of a subsidiary company to be known as the Lange Motor Truck Company which concern will erect a new and modern concrete factory with floor space of 40,000 square feet. When equipped the plant will begin the manufacture of 100 commercial vehicles as the first season's output.

The new industry is not altogether unfamiliar to the Lange concern as during the past five years it has represented the Gramm, Dayton and Chase lines, building bodies to suit the requirements of the purchaser. A feature of the Lange product will be that everything but the motor and wheels will be Pittsburg products. The engine will be a Continental. The best of material and workmanship will be employed and it is the plan of the company to manufacture a high grade machine.

KISSELKAR BRANCH NOT AFFECTED.

The KisselKar New England branch, Boston, is in no way connected with the Kissel Kar Kompany, a company in the hands of a receiver. H. B. Pruden, president of the former concern, states that none of the officials of the Kissel Kar Kompany are connected in any way whatsoever with his company.

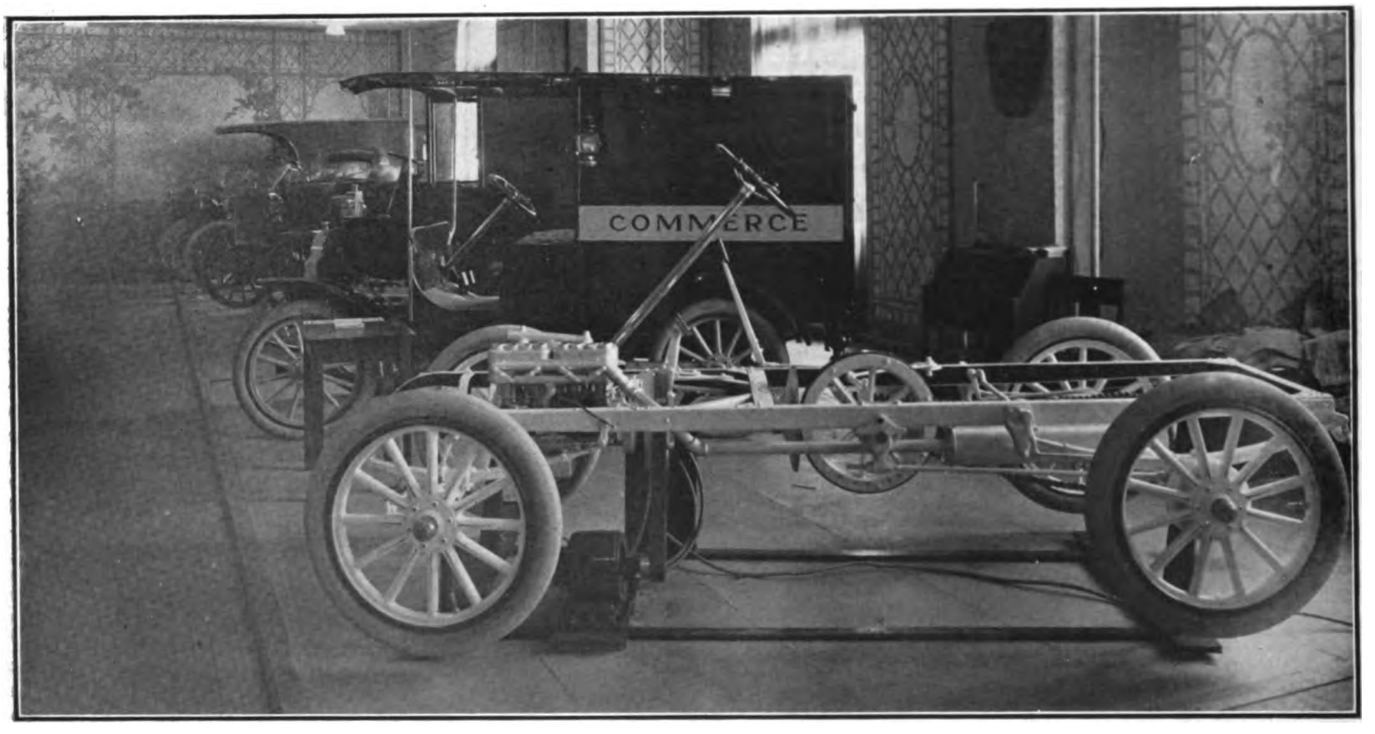
TRUCK DISPLAY AT GRAND CENTRAL PALACE.

SHARING interest with pleasure cars and accessories, motor trucks were displayed in the new Grand Central Palace, New York City, Jan. 10-17. So well pleased with the success of the venture were the exhibitors of this type of vehicle that a determined effort was made to secure the support of the management in a plan to continue the show until Saturday evening, Jan. 20, at which time the Madison Square Garden truck display was brought to an end.



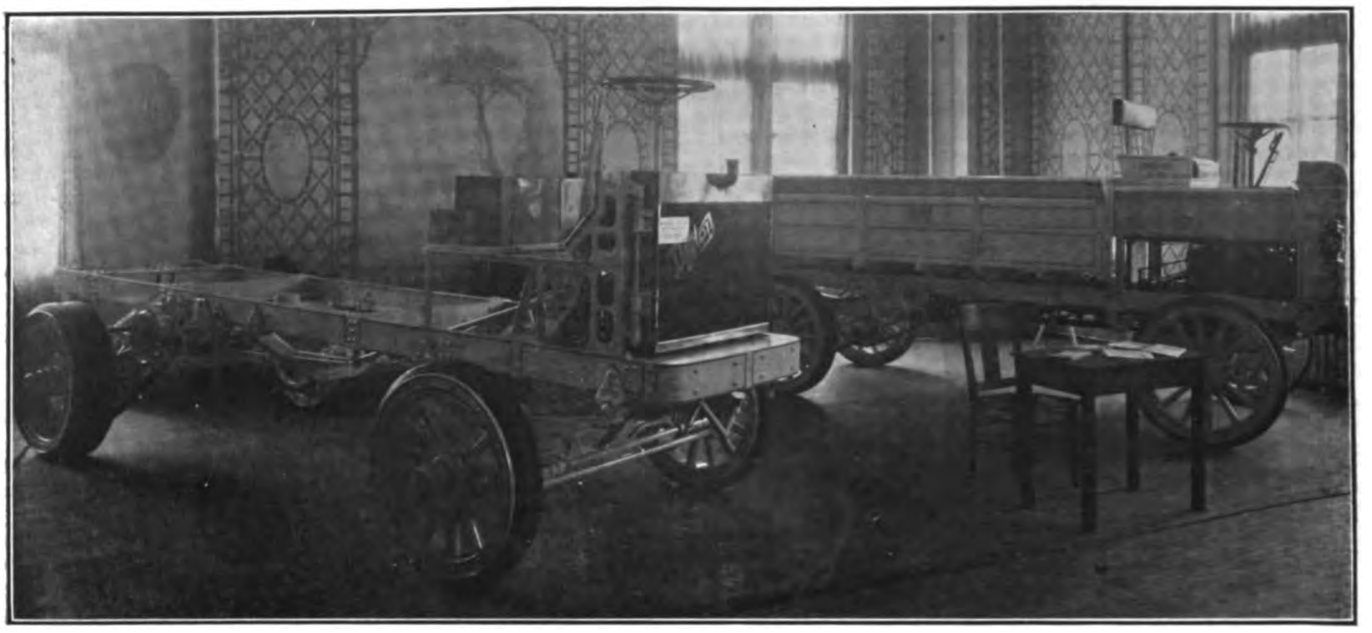
The exhibit was under the auspices of the National Association of Automobile Manufacturers, and the direction of S. A. Miles, general manager of that organization. The splendid appearance of the interior of the building was such that practically no decorations were needed. The following review of the exhibits presents first the make of machine, in alphabetical order, with name and address of the manufacturer, and the vehicles and chassis displayed by each.

Aries, J. Jaccard & Co., New York City. Seven-ton chassis and seven-ton brewery wagon. This is a French product and is more or less well known in America, although never exhibited at a New York show previously. Perhaps its chief distinguishing feature was the use of steel tires, although it is understood that rubber will be furnished upon order. A decompressor is fitted as an aid in starting, and a spring in the steering rod is designed to take shock off the driver's hands. The motor is very accessible, and is equipped with a governor. The general impression of the machine is one of great strength, and this is carried out even in minor details.

Atterbury, Atterbury Motor Car Company, Buffalo, N. Y. One-ton open delivery with standing top, two-ton stake body and three-ton brewery wagon with high panels. Motor is located in front under a hood, and driver and levers at the right. The line offers few changes from past design, although each model is now furnished with an automatic sealed governor, and fixed ignition by Bosch high-tension magneto.

Best, Durant-Dort Carriage Company, Flint, Mich. Eight hundred-pound chassis and panel delivery of same capacity. Driver is located above the motor with left hand control. This is an entirely new car, made in the factory of the Flint Motor Wagon Company in the same city. The motor is of the opposed cylinder type, rated at 12 horsepower, and is regulated by a centrifugal governor, which also automatically advances the spark when the speed of the engine requires it and insures a fully retarded spark for starting. A friction transmission is employed, comprising one driving and one driven disc, with final drive by side chain to rear axle. A particular feature is the yoke shaped steel frame which carries the discs and their shifting mechanism. This is secured under the main frame of the car with the yoke opening toward the rear. The countershaft, upon which the sliding disc is mounted runs in ball bearings carried at the ends of the yoke arms, and the driving disc is journaled in ball bearings at the apex of the yoke. The object of this construction is held to be that of imparting rigidity to this important part of the mechanism and preventing disalignment under heavy stresses.

Brooks, New York Auto Wagon Company, Brooklyn, N. Y. One buggy type delivery. Driver is placed in front with left hand seat location and right hand levers. This is also a new product in which several novel features are presented.



General View of One Corner of the Truck Display in Grand Central Palace, Friction Driven Commerce in the Foreground.

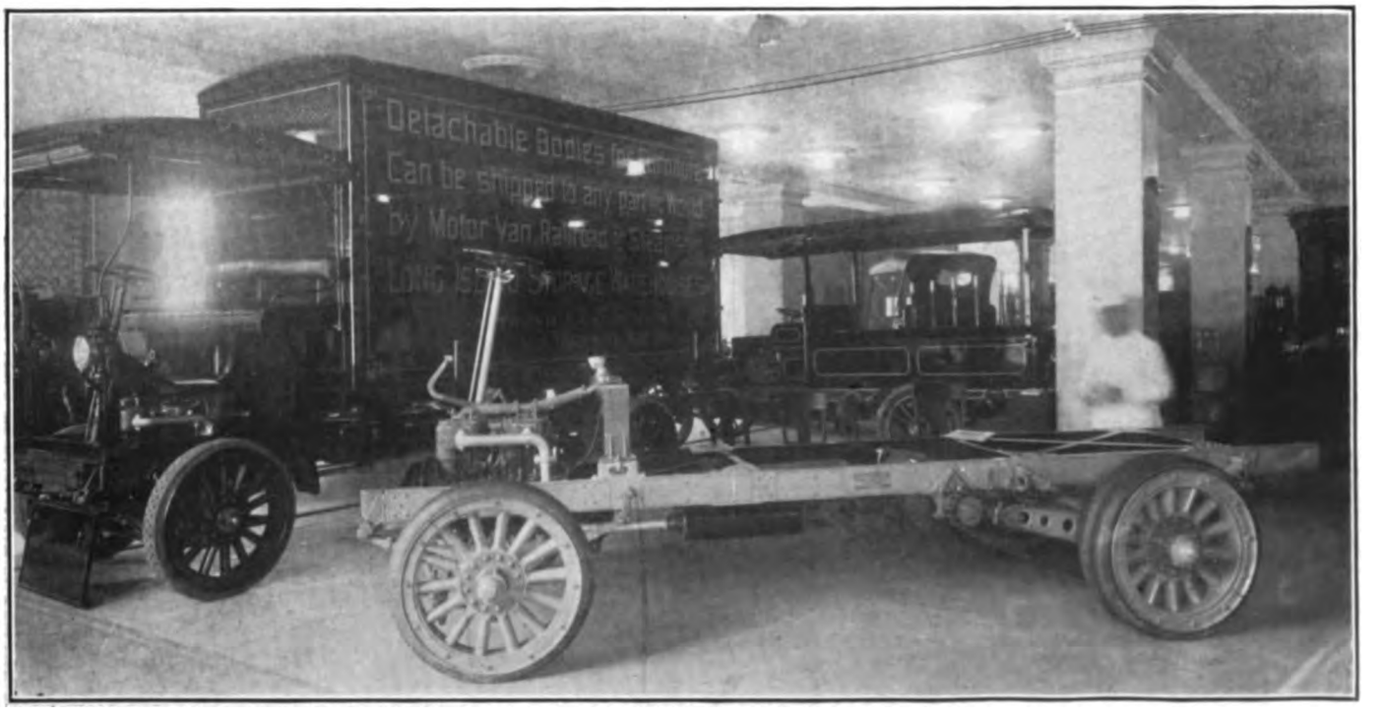
The motor is a two-cylinder, two-cycle, air-cooled horizontal unit, supported by means of shackles, transversely across the frame with crankshaft parallel with the rear axle, the distance between centres being varied by shifting the engine backward and forward to obtain the different speed ratios. The cooling flanges are built up of sheet copper vanes. Lubrication is accomplished by mixing the oil with the fuel as is usual with the two-cycle type. Ignition is by Bosch high-tension magneto.

The transmission is the roller device invented by Charles E. Duryea, in which the driving rollers are grooved and fit in correspondingly grooved rings bolted to the driving wheels and are attached to the crankshaft of the engine. There are two pairs of driving rollers, one for slow speed and reverse and a larger pair for high speed. Similarly there are two sets of rings, arranged concentrically with grooves facing.

Bringing the smaller rollers into contact with the outside rings, by shifting the engine with the speed control lever, obtains slow speed ahead. When these rollers are shifted so as to come in external contact with the inside

Digitized by Google

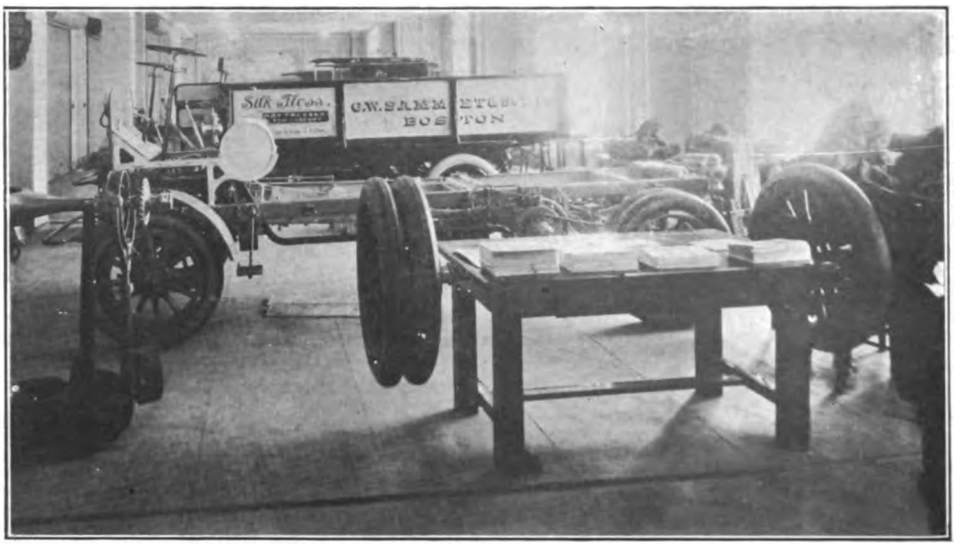
Durable Dayton Occupied a Position of Vantage, in Which It Was Possible to Call Attention to Its Constructional Details.



rings, reverse is secured. Shifting the rollers inward and forward brings the larger pair into internal contact with the outside rings and gives high speed ahead. The shifting devices are held to be simple and positive, being controlled by a single lever which is placed directly in front of the driver.

Cass, Cass Motor Car Company, Port Huron, Mich. Two-ton wide and low stake platform truck. Motor is in front under a hood, and is mounted on a sub-frame which rests on a three point suspension. The clutch is a patented combination of disc and cone. In all other respects there has been little change over previous construction. Special attention has been paid to springs, and the wheels are a trifle larger than is usual with vehicles of this capacity. A governor is fitted this year.

Chase, Chase Motor Truck Company, Syracuse, N. Y. One-ton chassis, one-ton panel delivery, 1500-pound panel delivery, one-ton screen body, 1.5-ton screen body and two-ton express flare board body. Motor is located in front under a hood, with driver and levers at the right. The 1.5 and two-ton vehicles are new, although they do not differ materially from the older and better known wagons of this make, with the single exception that they are of heavier construction. The motor is distinctive in that it is a three-cylinder, two-cycle, air-cooled unit, the system of air-cooling comprising a powerful suction fan, which is integral with the flywheel. An opening at the front and top of the motor, and another at the rear and bottom cause a strong current of air to be drawn in, circulated around the cylinders and passed out at the rear.



Commerce, Commerce Motor Car Company, Detroit. Half-ton chassis and panel delivery wagon of the same capacity. Motor is in front under a hood, with driver and levers at the right. The Commerce is another new design for New York shows.

The motor is a four-cylinder, four-cycle, water-cooled unit, with bore of 3.25 inches and stroke of 3.375 inches, rated at 20 horsepower. Cooling is by thermo-syphon, with flat tube vertical flow radiator and extra large reserve tank. Oiling is by the forced feed splash system, in which the lubri-

Comprehensive Showing of Universal Trucks, a Detroit Product Which Presents a Number of Distinctive Features.

Digitized by Google

Decatur "Hoosier Limited" Was Shown for the First Time in New York.

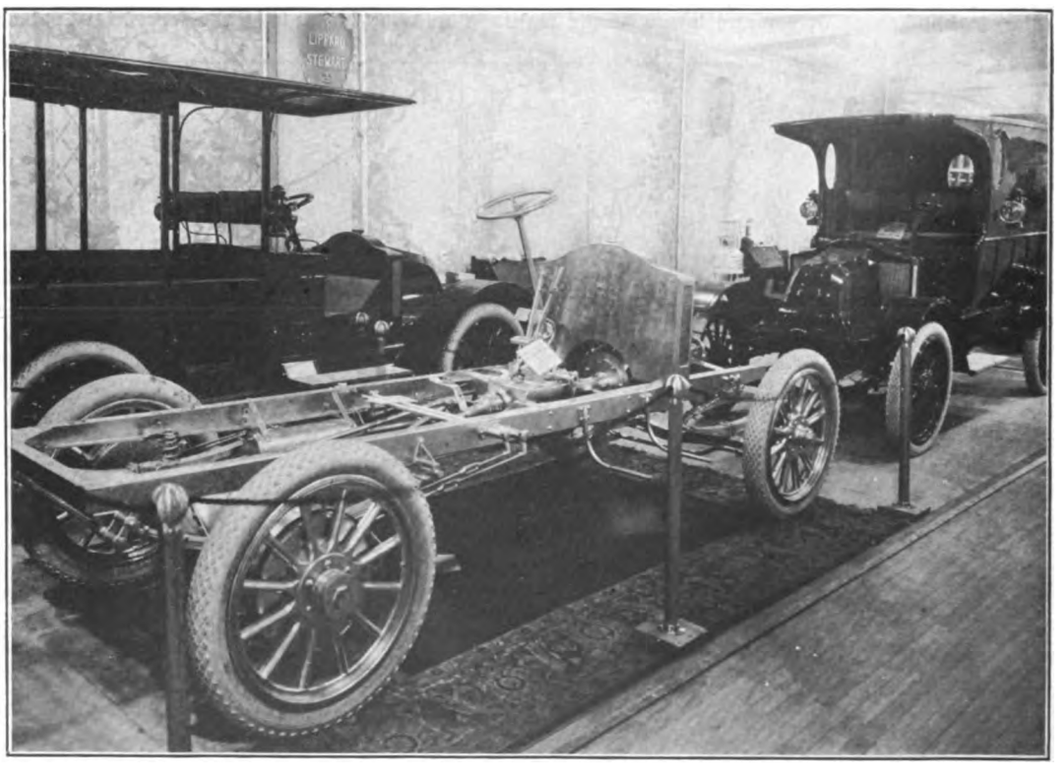
cant is forced direct to both end bearings, and runs back into the crankcase through passages provided for this purpose. Ignition is by Bosch high-tension magneto with fixed spark.

The friction transmission is controlled by one lever, and final drive is by single chain to the rear axle. Brakes are internal expanding on rear axle, operated by pedal, and the friction reverse provides for emergency. Frame is of pressed steel, heavily braced and reinforced. Springs are semi-elliptic with swinging shackles, said to be very resilient and easy riding. Wheelbase is 96 inches. Front axle is a heavy tubular drop pattern with special reinforced steering knuckles and arms, and the rear member is of the centre chain type with live axle and large differential. Wheels are of the artillery type with large ball bearings in the front hubs. Tires are solid, 36 by two inches, front and rear, although pneumatics may be had upon special order.

Commer, Wyckoff, Church & Partridge, Inc., New York City. One 4.5-ton chassis, one 4.5-ton high stake body and one imported 6.5-ton brewery wagon. Motor is in front under a hood, with driver and levers at the right. There practically is no change offered in this well known line, a distinctive feature of which is the gearset. This is of the constant mesh type, in which dog clutches serve to connect the individual gears to their shafts, only when permitted to do so by a special governor, which prevents such movement except when the engine speed is at a proper point with relation to the speed of the car.

Dart, Dart Manufacturing Company, Waterloo, Ia. One 1500-pound panel delivery and one 1500-pound flare board wagon. Driver is located above the motor, which is underneath the chassis, and levers are at the right.

The motor is a two-cylinder, four-cycle, water-cooled, opposed unit, with bore of 4.25 inches and stroke of five, with valves interchangeable and mechanically operated, rated at 16-20 horsepower. Cooling is by thermo-syphon with extra large honeycomb radiator of the square tube type. Ignition is by Splitdorf magneto and dry cells. Lubrication is by a pump oiler on top of the crankcase for the engine, while all other parts are provided with grease cups.



The transmission is an improved planetary, giving two speeds forward and reverse, low speed and reverse being secured by pedal and the high speed by hand lever. Clutch is a multiple disc member. Drive is by three roller chains. Brakes are internal expanding on rear wheels, operated by hand lever, with external contracting service brake on the jackshaft actuated by pedal.

Axles are square steel, 1.5 inches front and 1.75 rear, with ball bearing hubs. Frame is of pressed steel, securely braced with cross braces supporting the motor. Wheels are 34 inches, with 1.75-inch Firestone side wire tires. Springs are full elliptic front and rear. Wheelbase is 80 inches.

Decatur, Decatur Motor Car Company, Decatur, Ind. One 1.5-ton chassis, and low sided box body of the same capacity. Motor is under the floor with driver and levers at the right. Although this line was produced in a number of differing models last year, it is announced that the entire energy of the company will be devoted to the manufacture of but this one chassis in 1912.

The chief characteristic of the Decatur "Hoosier Limited," as it is called by the maker, is the accessibility of the power plant, a 30 horsepower Rutenber. The body is held in place by four bolts, and above this are located the dash and seat units, the former comprising the radiator, dash, floor boards, clutch and brake pedals, foot throttle, gasoline tank, side panel locks, change speed lever and emergency brake control. This also is held in place by four bolts, as are the seat and side panels.

The radiator is hinged at the side, so as to open like a

A "Golden Chassis" Occupied the Centre of the Lippard-Stewart Display.

Digitized by Google

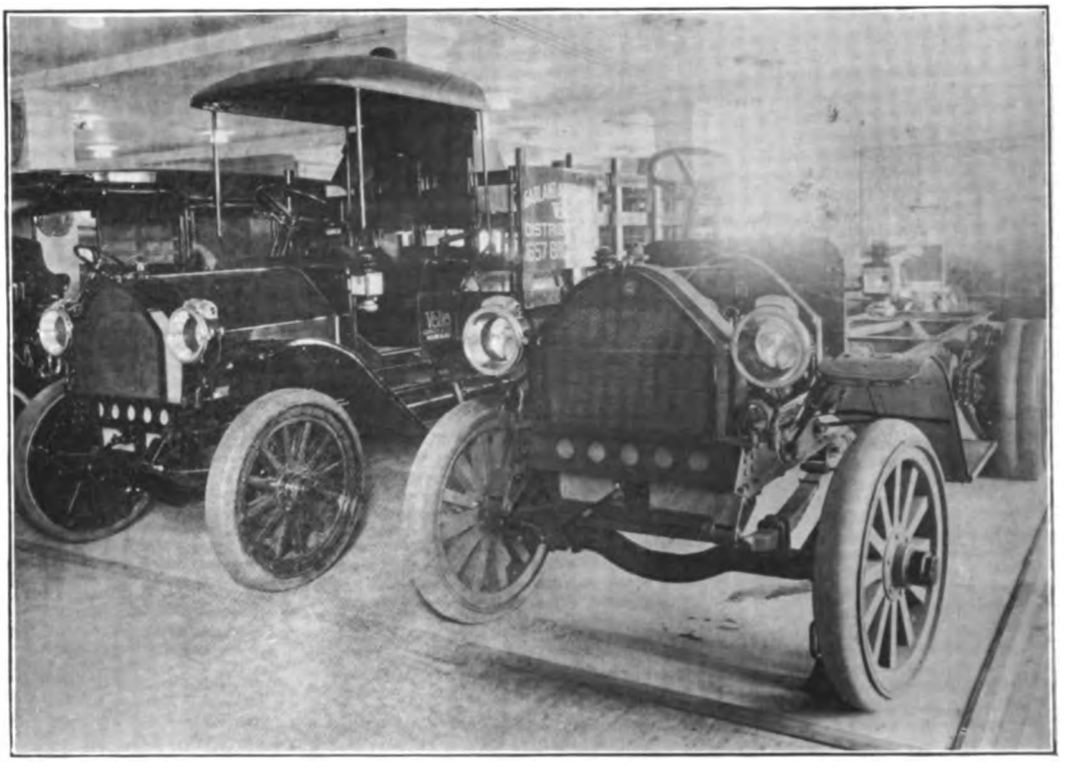
door. If it be desired to remove the entire power plant, the loosening of four bolts, makes it possible to lift off the seat unit, and loosening four more bolts permits the removal of the dash unit. This is claimed to be the work of but a few moments, and makes it possible to replace the motor without difficulty any time desired, whether the truck be loaded or not.

The rear spring system also is somewhat peculiar. In addition to the three-spring platform system, there is a cross spring extending from centre to centre of the main rear springs, its ends just above flat plates bolted to the tops of the main springs and clearing them by about .5 inch. The centre of this auxiliary member is clipped to a cross frame. Rollers at the ends prevent any undue friction and wear.

Durable Dayton, Dayton Auto Truck Company, Dayton, O. Three-ton chassis and 1.5-ton express wagon. Motor is under the floor. Driver is at the left with centre levers. The line comprises three models, the other being a five-ton machine, in which the same features are incorporated throughout, the only difference being in the size of the engine and the strength of construction. All motors are of the T head type with a tendency toward the long stroke. Lubrication is by forced feed through crankshaft to all bearings, no oil being carried in the crankcase.

The motor is located on a sub-frame and the transmission is carried on a three point suspension. Drive is through a Hele-Shaw multiple disc clutch to a selective sliding gearset, thence by propeller shaft, placed in a straight line with the engine and using two universal joints, one at either end, one of which is a sliding joint. Final drive is by side chains from the jackshaft to rear axle.

Eclipse, Eclipse Truck Company, Franklin, Penn. Two-ton chassis, one-ton flare board with top, three-ton screen side express and four-ton stake body with top and side gate. Motor is under the floor with driver and levers at the right. While it is announced that this line will carry a compressed air self-starter, it was not shown at the exhibit. A governor is fitted on all models.



The motor is on a sub-frame, and complete accessibility for replacement is provided by the removal of the entire seat framing, the work of a few minutes only. A cone clutch, leather faced, is employed. The transmission is of the selective type, providing three speeds forward and reverse, with gears always in mesh, combined with differential and jackshaft. Final drive is by chains.

Frame is of steel, four-inch channel section. Wheelbase is 106 or 112 inches. Wheels are of the artillery type, fitted with solid tires, single front and dual rear. Axles are roller bearing. Springs are of silico manganese, semi-elliptic in front and platform rear. Two sets of brakes are fitted, the service members being double duplex in jackshaft and the emergency, double internal expanding on rear hubs.

Federal, Federal Motor Truck Company, Detroit. Chassis, screen side express and low stake platform body, all of one-ton capacity. Motor is in front under a hood, with driver and levers at the left. In order to attain the utmost accessibility of parts liable to need attention, this company has arranged the mechanism in three units, motor, clutch and transmission, each removable independently of the others. A governor of the centrifugal ball type is located in the throttle, permitting a maximum car speed of 15 miles an hour.

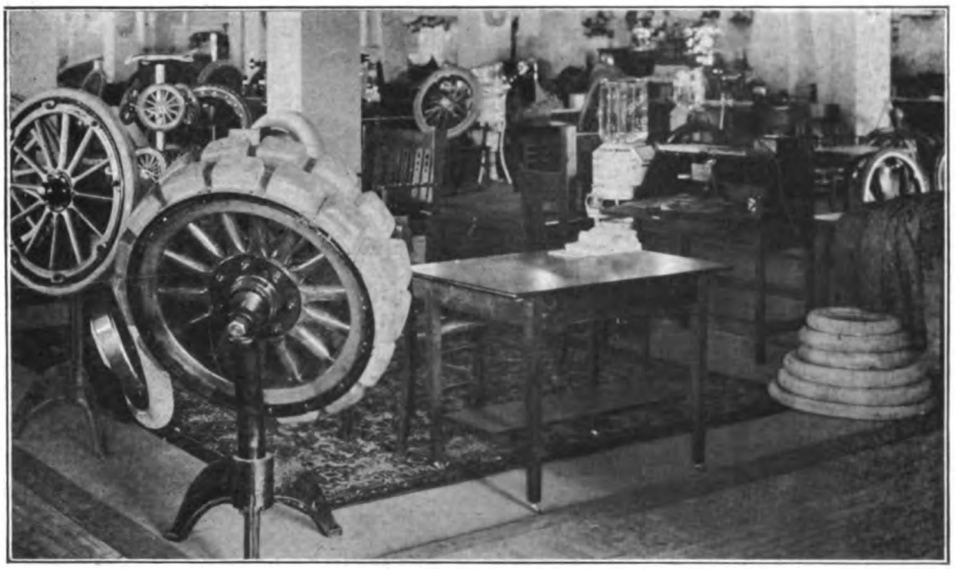
The four-cylinder, four-cycle, water-cooled motor is hung directly on the side rails of the frame, eliminating the necessity for the sub-frame. The selective sliding gear transmission, and the jackshaft to which it is bolted, are carried on a three point suspension, and the details of this mounting are somewhat noteworthy. Two horseshoe shaped brackets, with the openings hanging downward, carry the outer end of the jackshaft, being counterbored to receive the jackshaft tube brackets. Thus, by merely removing the retaining screws and sliding the tube brackets out a short distance from the frame, the rear end of the transmission-jackshaft unit drops down. It is then taken out of the chassis by moving the whole unit backward a short distance to disengage the universal mounting in front.

Drive is taken through a radius rod which consists of four parts; the hub brake centre which is mounted on the axle, the radius rod proper hinged to the hub brake centre, the radius rod connection which mounts on a spherical seat on the jackshaft tube bracket, and the radius rod adjuster which is threaded into the radius rod and the radius rod connection. It is claimed for this construction that it has several important points in its favor. Movement in any direction is taken care of without throwing any strain on the parts of the radius rod, as the front end is universally mounted, the hub brake centre is free to rotate around the axle, and the hinged joint at the rear allows sufficient movement to take care of any side sway that may occur.

Self-Starting Velie Line Was Well Represented by Three Vehicles of Varying Sizes.

Gramm, Gramm Motor Car Company, Lima, O. Two-ton express, three-ton chassis and six-ton dumper. Motor is in under the floor, with driver and levers at the right. Among the special features are the mounting of the engine on a sub-frame, permitting easy removal, and the fitting of a centrifugal ball governor on the throttle. All models are alike, with the exception of size and weight. Few changes are noted over previous construction.

The dumping body displayed is of special interest, the dumping feature being operated by the motor. A nickel steel pinion keyed into the rear end of the propeller shaft engages with either one of a pair of meshed gears of the same size hung in a pivoted cage. One of these communicates to a universal shaft extending forward to a point just behind the seat, driving the gears of the body actuating



Digitized by Google

mechanism. The cage is connected by a lever at the driver's seat mounted on a quadrant, the three positions of which give forward, reverse and neutral movements. Incorporated in the mechanism is an irreversible worm and wheel, which holds the body in any position when the control gears are shifted into neutral.

The winding drums for raising are located immediately back of the seat. Chains from these extend upward and over sheave wheels supported on a derrick, thence downward to the lower end of two upright legs on the front of the body, where they are secured by means of steel fastening brackets. The raising may be accomplished either with the truck at rest or while moving, so that it is possible to spread the load, the body being designed primarily for use in hauling road building materials.

Kelly, Kelly Motor Truck Company, Springfield, O. One-ton chassis, one-ton open express, three-ton express, and two-ton chassis fitted with 12-passenger hotel 'bus. In the smaller model, the motor is in front under a hood, while in the larger vehicles it is under the floor. Driver is at the left with central levers. All models are fitted with a governor. Practically no change has been made in the line, the distinctive feature being the air-cooled motor, which has been improved in a number of minor details.

Knickerbocker, Knickerbocker Motor Truck Manufacturing Company, New York City. Three-ton screen side brewery wagon and four-ton coal dumper. Motor is under the floor, with driver and levers at the left. This is a new product which has a number of distinctive features, chief among which is the method of mounting the motor and the provision made for its removal and replacement.

Impressive Showing Made by the Product of the Goodyear Tire & Rubber Company.

Beginning at the radiator, which is of the honeycomb type and suspended on springs or stanchions which are attached to or supported on the bumper, it will prove of interest to note the provision for accessibility. The bumper is hinged so as to swing open, carrying the radiator clear, so that the motor may be drawn out at will. The engine, a four-cylinder, four-cycle, water-cooled unit, is suspended on a hickory sub-frame, which may be drawn out as a drawer is withdrawn from a desk.

The clutch, a leather faced cone, also may be removed in 15 minutes, and the same holds true of the transmission, which is of the selective type, giving three speeds forward and reverse. This removability is still further extended to the jackshaft, of the full floating type, in a one-piece pressed steel housing. Still another feature is the placing of two coil springs directly under the frame on the rear axle, to provide an auxiliary member to take care of overloading.

Lubrication of the motor is by means of a positive gear driven pump located at the bottom of the commutator shaft and contained within the lower crankcase. The oil is filtered and forced through tubes to the main bearings and crankpits. A cup projection on the connecting rod caps picks up lubricant on every revolution and further assists in caring for the bearings. The oil level is shown by a ball in a gauge at the side of the crankcase. An overflow is provided which is held to eliminate flooding and smoking.

Koehler, L. E. Schlotterback Manufacturing Company, Newark, N. J. One 1600-pound panel delivery wagon and two panel bodies. Motor is under the chassis, with driver at the left and the levers at the right. This line is marketed by the H. J. Koehler Company of New York City, and is entirely new.

The motor is a two-cylinder, four-cycle, water-cooled, opposed unit, with bore of 5.25 inches and stroke of four. Lubrication is mechanical and integral. Cooling is by thermo-syphon, through large pipes and large radiator at the front. The carburetor is of the float feed type. Ignition is jump spark with true high-tension Splitdorf magneto, the instrument being located on top of the motor and driven direct by enclosed gears.

Drive is in a direct line from motor to jackshaft, immediately connected by universal joint. Final drive is through double side chains to rear wheels. Transmission is of the planetary type. Clutch is a cone. Service brake is on the jackshaft, metal to metal with 75 square inches of braking surface and at a three-to-one reduction from the rear wheels. Emergency brakes also are metal to metal, operated independently.

Frame is channel section steel, U shaped. Springs are semi-elliptic in front and full elliptic in rear. Front axle is a one-piece drop forging with knuckle yokes integral. Rear member is two inches square. Tires are two-inch solid, front and rear. Wheelbase is 76 inches. Wheels are of the buggy type.

Lauth-Juergens, Lauth-Juergens Motor Car Company, Fremont, O. One-ton flare board express, and three-ton high side brewery wagon with side gate at the forward end. Motor is under the floor, with driver and levers at the right. A particular feature of the exhibit was the driver's cab on the three-ton model, this being completely enclosed with glass windows on all sides, giving the occupants complete protection from the weather.

The motor is a Rutenber four-cylinder, four-cycle, water-cooled unit. Lubrication is by splash system. Ignition is by Bosch or Mea high-tension magneto and battery. The clutch is the firm's own patented, three-piece disc member, having only three parts, and consisting of two metal discs between which is a fibre disc with large friction surface. The clutch has a universal joint between the flywheel and transmission, making it flexible and eliminating all end strain between crankshaft and transmission.

The transmission is of the selective sliding gear type, giving four speeds forward and reverse. This also is the firm's own patented device, and is housed with the jackshaft as a unit. Four semi-elliptic springs front and rear are made of chrome-vanadium steel. Axles are heavy, solid steel forgings with heavy steering yokes and ball bearings throughout. Emergency brakes are contracting on drums on jackshaft, while service members are internal expanding, operating on drums on the rear wheels. Wheels are 38 inches in diameter, equipped with five-inch solid tires in front and four-inch dual members in rear.

Lippard-Stewart, Lippard-Stewart Motor Car Company, Buffalo, N. Y. Chassis, panel delivery and open delivery, all of 1500 pounds capacity. Motor is in front under a hood. Driver is at the left with centre levers. The startling feature of the display was the "golden chassis," on

Digitized by Google

which the parts had been so skilfully gilded as to leave nothing in its original color except the tires.

Accessibility and the elimination of parts which might cause trouble in the hands of an inexperienced operator are among the chief claims for the Lippard-Stewart. Each unit is so arranged that it is possible to remove and replace it without disturbing any other unit. The small four-cylinder motor, and the low geared (five-to-one) shaft driven axle make a combination which is held to give a surplus of power for all occasions with a remarkably small consumption of gasoline and oil. Fixed ignition is another attempt to reduce complications.

The radiator mounting follows foreign practise, in that it is mounted behind the motor at the dash. Reduced vibration is provided by suspension on coiled springs. The water pump is eliminated, as well as the belt driven fan, suction blades on the flywheel taking the place of the latter.

The selective sliding transmission provides three speeds forward and reverse, and is located immediately under the floor boards, where it can be removed easily should occasion require. Instead of the chain drive construction a shaft drive and full floating rear axle are employed. Particular attention has been paid to the design of the frame. In front it is curved inward about three inches to give a short turning radius. Two sets of brakes are fitted, expanding and contracting on the rear axle.

Maxim Tricar, G. H. Bushnell Press Company, Thompsonville, Conn. One tricar, fitted with two-cylinder, air-cooled vertical motor, mounted over the front wheel. Although described as an air-cooled engine, a pair of hollow ribbed columns containing water is provided for cooling the exhaust valves.

The particular feature of the construction is the speed changing device, which is of the hydraulic type. A small cylinder-like compartment, somewhat smaller than the crankcase of the engine and carried on the extension of the crankshaft, is filled with oil. When no power is to be transmitted, the vanes on the shaft disc are folded, and if the motor be started then the disc and its vanes will churn idly in the oil. When the handle is turned upward so as to open the vanes, the oil starts circulating in the casing being thrown violently from the pockets formed by the movable vanes into those formed by the fixed members, and imparts to the latter, and of course to the casing, the sleeve and the attached sprocket, chain and the front wheel of the car, a rotary motion. When the movable vanes are raised still further, there is more violent movement of the oil, which is thrown with great force and in greater volume into the fixed vanes, and more power is transmitted, until on full opening, when there is just room for the vanes to clear each other, the shaft disc and the sprocket carrying casing rotate almost together, there being a very small amount of slip or lost motion.

Modern, Bowling Green Motor Car Company, Bowling Green, O. One 1500-pound chassis, one 1500-pound open body and one 1000-pound screen side body. Motor is in front under a hood, and driver either at the right or left, with right hand levers placed accordingly. This is another new product, so far as the New York shows are concerned, and is made only in the light delivery class.

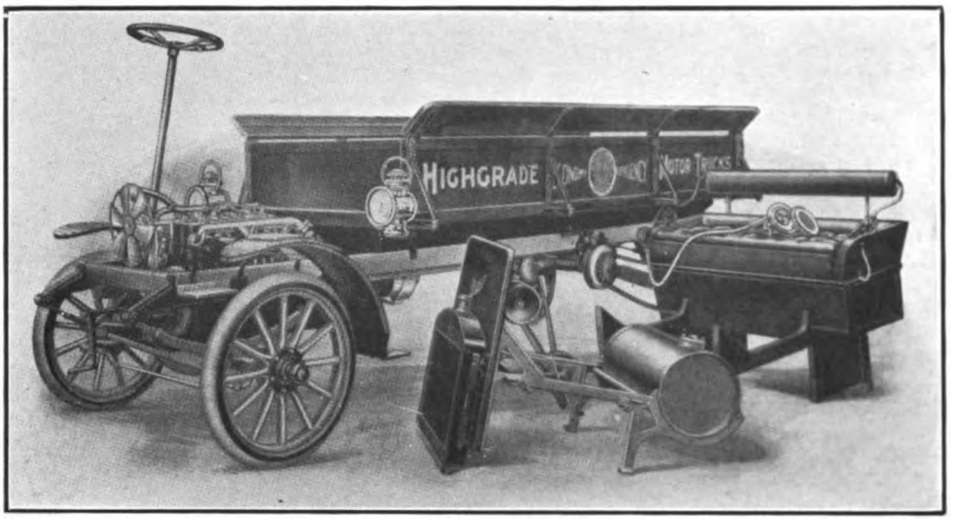
For the smaller wagon the motor is rated at 25 horsepower, and for the larger 30. Both are of the block type with all valve mechanism enclosed, and water-cooled by forced circulation. The lubricating system includes a positively driven pump wth sight feed on the dash. Drive is through cone clutch, three-speed selective sliding gearset, jackshaft and side chains to rear wheels. Pneumatic tires are fitted as standard equipment, but solids may be had if preferred.

Motor Wagon, Motor Wagon Company of Detroit, Detroit. Three-seated 'bus, stake platform, panel delivery, open side flare board, open side with top, and chassis, all of 800 pounds capacity. Motor is in front under a hood, and driver at the left with centre levers. This vehicle also was shown for the first time.

The motor is a two-cylinder, two-cycle, water-cooled, horizontal opposed unit, with bore and stroke of four inches, rated at 16 horsepower. Cooling is by thermo-syphon. Lubrication is by positive mechanical sight feed oiler. Ignition is by Bosch high-tension magneto with fixed spark.

The transmission is of the planetary type, with self-contained multiple disc clutch, the entire assembly being mounted on ball and roller bearings and enclosed in an oil tight case. Three speeds forward and reverse are obtained. Drive is by double side chains from jackshaft to rear wheels. Frame is of steel, channel section. What is claimed to be a three point spring suspension is employed, this comprising one set of semi-elliptic members in front and two full elliptic in the rear. Wheels are of the artillery type, 32 inches in diameter, fitted with two-inch solid tires in front and 2.5-inch solids in the rear, although pneumatics may be had at an extra charge.

Newark, Newark Automobile Manufacturing Company, Newark, N. J. One 1000-pound chassis, one 1500-pound panel delivery wagon and one 1.5-ton chassis. Motor is in front under a hood, and driver at the left with centre levers. This new truck has a number of distinguishing features, chief among which may be mentioned the worm drive.



Where United States Tires Were Exhibited in the Accessory Division.

Everything about the car is enclosed. The motor is a four-cylinder unit, cast en bloc, with all working parts enclosed, the covering of the valve mechanism being the first step in what is claimed to be a special effort to reduce excessive noise. The leather faced cone clutch runs in oil. The three-speed selective gearset is carried in a casing which is secured to that of the clutch, which in turn is bolted to the motor crankcase, making a complete unit. The worm and gear are imported from abroad.

On the steering column is a little brass cylinder from the top of which rises a small rod with a ball shaped head. When the motor is running and the oil is circulating actively, the pressure of the lubricant, communicated to the little cylinder through connecting pipes, keeps the ball ended rod pressed up and the driver can determine at a glance that the oil is moving as it should. In the dark, he has but to press his finger on the ball, and if it be down, either the oil is exhausted or something else is wrong.

The enclosed feature is extended to the ends of the semi-elliptic springs and joints, which are protected by metal

Digitized by Google

Decatur Seat and Dash Units Dismounted to Illustrate Accessibility of Power Plant.

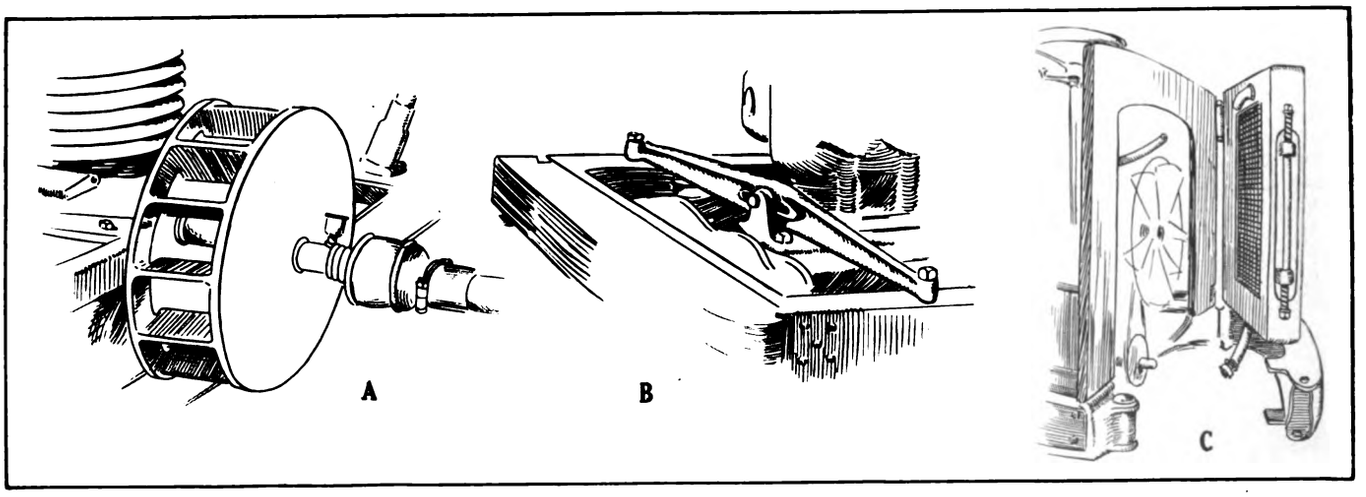
hoods, which exclude all dust and retain lubricating grease. In fact, this attention to detail in this regard, throughout the entire mechanism, has been carried to an extreme.

Packers, Packers Motor Truck Company, Wheeling, W. Va. Two-ton chassis and two-ton panel butchers' wagon. Motor is in front under a hood, with driver and levers at the right. The line also includes a four-ton model, which was not shown. Standard design has been followed throughout.

The motor is a four-cylinder, four-cycle, vertical unit, water-cooled and with inlet and exhaust valves on opposite sides, mechanically operated. Lubrication is by force feed to all crankshaft and camshaft bearings and splash for connecting rod and cylinders. Ignition is by dual system, Splitdorf low-tension magneto and Splitdorf non-vibrating coil on the dash.

The clutch is a Hele-Shaw multiple disc. Transmission is selective with three speeds forward and reverse, and is mounted on the jackshaft, both being on a three point suspension. Final drive is by double side chains to rear wheels. Frame is of steel, channel section, heavy reinforced in the centre. Springs are long and wide, of silico-maganese steel. Front axle is an I beam section, with very large steering knuckles. The rear axle is dead, rectangular in section. Two complete and independent brakes are employed, the service members of the contracting type on the jackshaft and the emergency on the rear wheels.

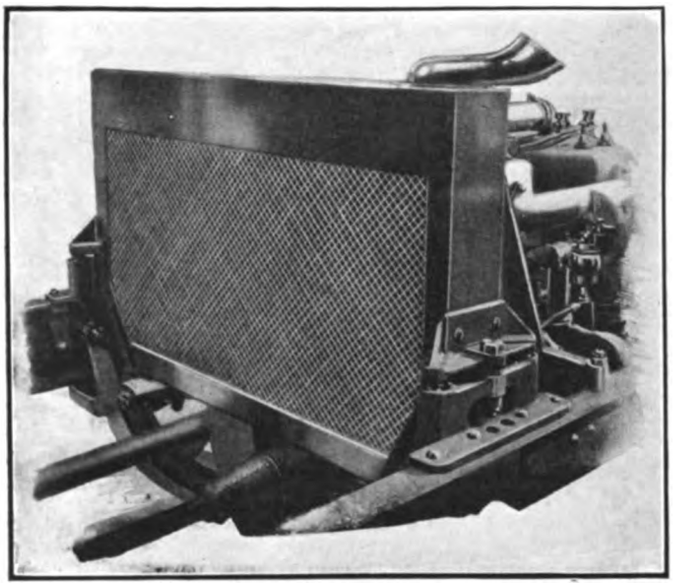
Poss, Poss Motor Company, Detroit. Chassis and panel delivery wagon, both of 100 pounds capacity. Motor is in front under a hood with driver and levers at the right. This is another new make employing the friction transmission.



The motor is a four-cylinder, four cycle unit, with bore of 3.5 inches and stroke of 4.75, and cylinders cast en bloc. This is hung on brackets bolted directly to the main frame. The driving disc is carried in bearings in a cross frame and the shaft of the driven disc is supported on the main frame. Final drive is by single chain to the live rear axle, which runs on roller bearings. Solid tires are fitted as standard, although pneumatics may be had if preferred.

Rowe, Rowe Motor Company, Coatesville, Penn. One 1500-pound wagon with side seats and one 2500-pound high side box body with hand operated winch for handling stone. Motor is in front under a hood, with driver and levers at the right. While these cars are offered with a worm drive, these exhibited were not so equipped. In fact, it may be stated that the business of this concern is rather the manufacture of motors, and the production of trucks is undertaken on special order, the claim being that it is impractical to construct a line of stock models which will meet the varied requirements of individual users.

The motor is a four-cylinder, four-cycle, water-cooled, vertical unit, with inlet and exhaust valves on opposite sides. Extreme care has been taken in the design so as to protect all moving parts and bearings from dust and to prevent oil from leaking out. All attachments are so placed as to be easily accessible. Magneto, oil and water pumps are gear driven. Lubrication is by a self-contained system in the crankcase, circulated by gear driven pump, forcing the oil through ducts drilled into the crankshaft to each of the crankshaft and connecting rod bearings. Oil thrown off by the movement of the cranks lubricates the walls of the cylinders, camshaft and gears, valve tappets, etc.



The multiple disc clutch runs in oil. The transmission is of the three-speed selective type. Two complete sets of brakes are fitted on the rear wheels. The service members are external contracting and the emergency, internal expanding. Frame is of pressed chrome-nickel steel, channel section. Springs are semi-elliptic in front and platform rear. As stated previously, final drive is by chain or worm, at the option of the purchaser, the choice being governed by the service which is expected of the completed vehicle.

Sanford, Sanford-Herbert Company, Syracuse, N. Y. Chassis, open flare board body and express, all of one ton capacity. Motor is under the floor, with driver and levers at the right. This make has been known as the Sanbert, the name being taken from those of the principal stockholders in the company, but the public has so often confused the name of the car with the first portion of the firm name that

A Few Mechanical Features at Grand Central Palace Display: A, Chase Fan Flywheel; B, Universal Motor Support; C, Knickerbocker Radiator Mounting.

Digitized by Google

Radiator Under Driver's Seat on Universal.

it has been decided to accept that verdict and it will be known in the future as the Sanford.

The motor is a three-cylinder, two-cycle, air-cooled unit, with bore of four inches and stroke of 4.5, rated at 25 horsepower. Ignition is by Bosch high-tension magneto. The planetary change speed gearing is employed, and the gear-case is attached to the forward side of the jackshaft housing. Final drive is by side chains to the rear wheels, which are 38 inches in diameter, fitted with 2.5-inch solid tires. A belt driven fan furnishes air circulation when the motor is running.

Schacht, Schacht Motor Car Company, Cincinnati, O. One three-ton flare board express wagon. Motor is located in front under a hood, and driver at the left with centre levers. Although on the market for the past two years the Schacht was first displayed in New York at this show. The line also includes two and four-ton models, but in all essential characteristics they are the same. Few changes in mechanical construction are to be noted, the solid, substantial heavy duty type of vehicle with plenty of power and transmission systems well able to convey it to the rear wheels having demonstrated its satisfactory design under all circumstances in the past.

Sullivan, Sullivan Motor Car Company, Rochester, N. Y. Half-ton panel delivery wagon and 1500-pound flare board body. Motor is in front under a hood, and driver at the left with centre levers.

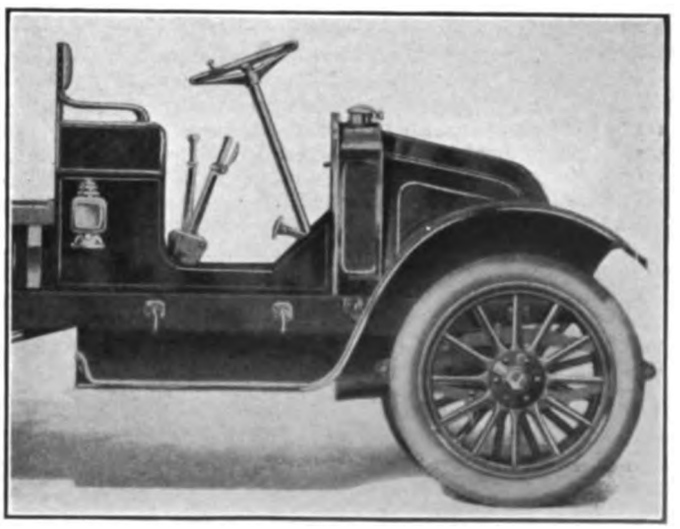
The engine is a two-cylinder, four-cycle, water-cooled, horizontal opposed unit, with bore and stroke of 4.5 inches, rated at 18 horsepower. This is suspended by cylinder head brackets from the main frame. Cooling is by thermo-syphon. Lubrication is by mechanically operated oiler, pumping oil to each of the cylinders, main bearings and direct to each connecting rod bearing. The crankshaft is drilled to allow the lubricant to be pumped to the latter. Valve operating mechanism is oiled by splash. Ignition is by Bosch magneto.

The transmission is of the planetary type. Clutch is of the cone type. Final drive is by side chains to the rear wheels. Brakes are equalized internal expanding members on rear wheel drums. Frame is of angle steel, hot riveted and securely braced at corners and with cross braces. Springs are full elliptic in front and full elliptic scroll in the rear. An auxiliary spring also is fitted at the rear. Tires are solid, 36 by 2.5 inches front and rear.

Universal, Universal Motor Truck Company, Detroit. Chassis and two warehouse trucks, all of three tons capacity. Motor is under the floor with driver and levers at the right. A particular feature of this line is the mounting of the radiator, which is behind the motor, on springs under the driver's seat.

The motor is a four-cylinder, four-cycle, water-cooled unit, with bore of four inches and stroke of 5.5, rated at 30 horsepower. Lubrication is by the self-contained, constant level splash system, from main reservoir to the plunger pump to sight indicator on the dash. Speed is controlled by an automatic governor of the ball type, acting directly on the main throttle control. Ignition is by jump spark, current being supplied by a Bosch dual magneto.

The clutch is a multiple disc of the dry plate type. Transmission is selective sliding, with three speeds forward and reverse. Final drive is by side chains to rear wheels. Frame is of steel, channel section. Service brakes are external contracting on brake drum located on the jackshaft and integral with the differential case. Emergency members are internal expanding in rear wheel hub drum. Four semi-elliptical springs are employed. Front axle is an I beam section, while the rear member is a heavy rectangular section. Wheels are 36 inches in diameter, fitted with five-inch single solid tires in front and four-inch dual in rear.



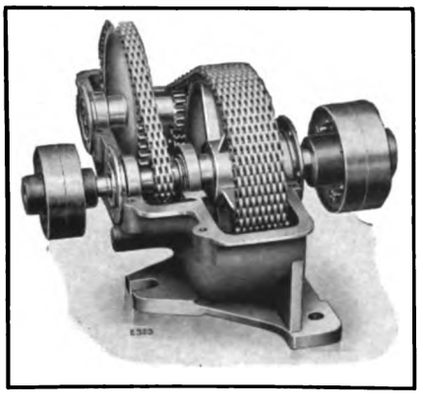
Veerac, Veerac Motor Company, Anoka, Minn. Chassis and carpet house wagon with high side panel and standing top, both of 1500 pounds capacity. Driver is located at the left with left hand levers. The name of this car is made up from the initials of the words, "valveless, explosion every revolution, air-cooled," and the power plant is accurately described thereby, it being a two-cylinder, two-cycle, air-cooled, horizontal opposed unit.

This is hung crosswise of the frame and has two separate and distinct throttles, one for each cylinder, controlled by two throttle levers on the steering column. This is held to make it possible to control the engine, either by throttling down one or both cylinders at a time, or cutting out one member and running the power plant as a one-cylinder motor. The throttle valves are at the intake ports of the cylinders, thereby eliminating the possibility of disturbing the action of the carburetor.

Another feature is the installation of a pipe leading directly from the gasoline tank to the cylinders with a shut-off cock operated from outside the frame. By opening this cock for a moment gasoline is injected into the cylinders and starting is thereby made easier, it is claimed.

Velie, Velie Motor Vehicle Company, Moline, Ill. Three-ton chassis, three-ton low stake body and 1500-pound delivery wagon. Motor is in front under a hood, with driver and levers at the right. Although by no means a new product, this was the first time it was shown in New York City. In the main, the construction follows standard design, incorporating only such features as have been tried out thoroughly and found satisfactory under all conditions. A Prest-O-Starter and governor are fitted as regular equipment this year.

One particular feature is the differential lock, by means of which it is possible to depress a pedal on the foot board and lock the mechanism so that the rear wheels turn as if on a solid axle. The design of the radius rod also is unusual. Instead of being rigid when subjected to endwise pressure, this is made with telescoping joints held open by



Radiator Behind Motor on Lippard-Stewart.

Digitized by Google

heavy helical springs, so that the sudden application of power, instead of transmitting severe shocks, is cushioned.

Victor, Victor Motor Truck Company, Buffalo, N. Y. Two-ton warehouse truck. Motor is in front under a hood, with driver and levers at the right. Although the full line includes a number of models, few mechanical changes are noted over past years, the construction having been such that it has given abundant satisfaction under varying degrees of service. A multiple disc clutch is fitted as standard, although a cone clutch will be substituted if desired.

Speed Reduction Gearbox for Electric Motors.

Walter, Walter Motor Truck Company, New York City. Three-ton chassis, three-ton furniture wagon and five-ton chassis. Motor is under the floor with driver and levers at the right. The principal feature is the adoption of the new Westinghouse change speed gear mechanism, which will be standard in all future productions of the company.

In this, which gives three speeds forward and reverse, the gears always are in mesh and are engaged by individual clutches of the multiple disc type mounted on concentric sleeves, and operated by the progressive movement of a lever, which engages the clutches in succession. The first movement of the lever compresses the discs of the low speed clutch, which is caused to rotate, carrying with it a sleeve, on the opposite end of which is a gear meshing with a countershaft gear. Further along the countershaft another gear engages with a gear on the tailshaft, which is connected by a universal joint to the propeller shaft.

Further movement of the operating lever carries the compression further, and the second clutch is engaged, without releasing the first, however. The second clutch drives another sleeve inside the first, and it also carries a gear and drives the countershaft and tailshaft in the same way as the first speed gearing, the difference being that the gears in the second set are proportioned to give higher speed at the tailshaft.

In order to prevent locking, the driven gears on the countershaft are on roller clutches, so that when the second speed is engaged the first speed roller clutch overruns. On third speed, drive is direct, first and second gears on the countershaft overrunning on their roller clutches. When speeds are changed with this gear the transition from one to another is said not to be perceptible. The entire mechanism, including the clutches, is enclosed in a single casing, and the shafts and sleeves run on annular ball bearings.

ELECTRIC COMMERCIAL VEHICLES.

Argo, Argo Electric Vehicle Company, Saginaw, Mich. One 1000-pound chassis, one 1000-pound panel delivery, and one one-ton low side panel delivery. This new line was notable because of the manner in which the motor, a Westinghouse ironclad type, and transmission are combined in a unit. Drive is through a short shaft and herringbone gears.

The battery, provided to suit condition of use and preference of the purchaser, is underslung amidships. Control is located on the steering mast, interlocking with ratchet brake, so that the latter cannot be set with power on, or power applied with brake set. This is claimed to be a distinct Argo feature.

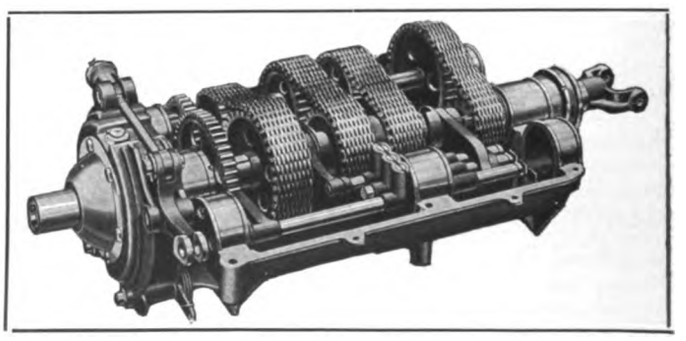
Hupp-Yeats, Hupp Corporation, Detroit. One screen side delivery of 1000 pounds capacity. This is a new addition to the Hupp-Yeats line, although the chassis does not differ materially from that of the well known pleasure vehicle of the same make, except that it is slightly changed in shape and somewhat heavier throughout.

Walker, Walker Vehicle Company, Chicago. One 750-pound chassis, one 750-pound screen side delivery, and one 1.5-ton panel delivery. Internal drive with all gearing enclosed in the disc rear wheels; a single electric motor with its shaft extending across from wheel to wheel, each end of the motor shaft driving a wheel, and a differential in the motor shaft are the principal features of the line.

The motor is enclosed in a hollow casing which forms the rear axle. On either end of the shaft is a small spur pinion which meshes with two large gears, the latter in turn meshing at diametrically opposite points, with a large internal gear secured to the inside of the wheel rim. The two intermediate gears turn on studs on opposite ends of the yoke, which is mounted on the end of the hollow axle casing projecting into the wheels.

Owing to the peculiar construction of this rear axle the motor is extremely accessible. The upper portion of the casing is removable, when six capscrews are taken out, and the whole of the motor with differential on the shaft, may be examined.

JANUARY GENERAL VEHICLE SALES.



It will prove of interest to note that the January sales of General Vehicle electric trucks, made by the General Vehicle Company, Long Island City, N. Y., totalled 158. Jacob Rupert, a New York brewer, ordered 21, making his fleet 72 in all. Peter Doelger, another New York brewer, ordered eight, making a total of 47. Other large orders were: Muehlback, seven, making 10; Commonwealth Edison, nine, making 15; Schaefer Brewing Company, eight, first order; General Baking Company, 10, initial order. Sixty-nine per cent. of the 1911 business of the company was reorders, and Feb. 1 finds it with 671 General Vehicle electrics bought by 25 customers alone.

BRITISH CARS USE COVENTRY CHAINS.

There is a growing tendency abroad to adopt a noiseless chain for driving the camshaft, magneto and pump of the power plant and many of the best known English makes displayed cars thus equipped at the recent Glasgow motor exhibition held recently. Not only is the chain drive being utilized in the motor but also in transmissions, etc.

Among the exhibits of interest at the Scottish show was the display of the Coventry Chain Company, Ltd., Coventry, England, of which S. Hoffnung & Co., Ltd., 118 Broad street, New York City, is United States representative. The complete product of the British concern was shown, as well as a chain driven change speed gearbox which attracted considerable attention at the Olympia show and which is depicted in an accompanying illustration. This design makes for silence and efficiency and is being tested by American maufacturers with a view of application to their cars. In Germany a plant is being erected to produce the gearbox for supply to the motor builder.

The application of the silent chain to a speed reduction gearbox is shown in the illustration herewith and it is claimed that the design solves effectually the question of reducing speeds of electric motors to the desired number of revolutions with a minimum loss of power, by either double, treble or quadruple reductions. In addition to efficiency, silence, reliability and longevity are emphasized.

Coventry Noiseless Chains Fitted to Change Speed Gearbox.

MIDDLE WEST AWAITS CHICAGO SHOW.

EACH year the importance of Chicago as a centre in which to make display of commercial vehicles has been appreciated more and more by the manufacturers. While there was some question regarding the advisability of holding a separate show for this type of automobiles in New York City in 1911, there was little doubt in the minds of those who had studied the field that the second attempt of this nature would prove successful in Chicago. It must be remembered, in this connection, that the metropolis of the Middle West was the first city in the country to inaugurate the scheme of holding an exclusive motor truck exhibition. But that was some years ago, when this branch of the industry had not as yet been fully recognized as a separate institution, and the attempt was largely in the nature of a failure. However, the industrial transport show of 1911 was a decided success from every point of view, and there is little question that the event which will be held in the Coliseum and First Regiment Armory, Feb. 3-10, will be even more so.

The second annual motor truck display will be under the auspices of the National Association of Automobile Manufacturers, and the direction of S. A. Miles, who has managed all of the automobile shows held in the Coliseum, whether these have been combined exhibits of pleasure and commercial lines, or of a separate character. The interiors of these two buildings lend themselves admirably to the decorative art.

It is announced that the treatment of the Coliseum will be purely architectural throughout. The girders will be hidden by a mosaic design, relieved here and there by mural paintings, the whole effect being light in color, white, amber and gold predominating. The two end walls above the gallery will be covered with immense drop curtains. The building will be lighted by 36 large chandeliers.

The main floor of the armory will be transformed in much the same manner as last year. Staff walls, pillars and vases of the Louis XIV design will be combined with flowers, foliage and ornamental lamps. For the first time, the ceiling will be flat instead of circular. A drop curtain running from the second to the third gallery will surround the entire structure.

There were 72 different makes of machines displayed at the two shows in New York City last month. Chicago will see no less than the same number, and all in one exhibition, albeit both structures will be utilized in the display of trucks this year, whereas the Coliseum was found wholly adequate for this purpose in 1911. Incidentally, it may be mentioned that this number is based upon advance reports, and it is known that several other makers have secured space within the last few days, so that the 1912 Chicago exhibit will be far the largest showing of industrial transports ever assembled in any city. There were 57 different concerns represented last year.

It is well to note that many makes will be shown which were not seen in New York. Included in this list are the following: Adams, Avery, Chicago, Clark, Diamond T, Dorris, F-C-S, Four Wheel Drive, Mais, Mercury, Monitor, National, Old Reliable, Rambler, Rassel, Service, Smith, Staver, Stegeman, Sternberg, United States and Wilcox.

SPLENDID SETTING AT MILWAUKEE.

The Milwaukee Automobile Dealers' Association, Milwaukee, Wis., held a combined showing of pleasure and commercial cars in the Auditorium in that city, Jan. 13-20. The interior of the building was converted into a garden within a wall, on which was entwined vines and Alabama smilax, making a decidedly attractive setting. The truck section was most complete in every way, practically every line represented in the city being shown. Despite the very cold weather, the attendance was most satisfactory, and it is understood that considerable business was transacted. The following concerns made display of power wagons:

Universal Machinery Company, Universal; Buick Motor Company, Buick; American Locomotive Company, Alco; Crown Commercial Car Company, Crown; Orrin R. Hughes, Garford; Jos. Obernberger & Sons Company, Monitor; Peerless Motor Car Company, Peerless; Brodessor Motor Truck Company, Brodessor; Curtis Automobile Company, Reo; Hickman-Lauson-Diener Company, Ford; McDuffee Automobile Company, Chase; D. F. Power & Co., Menominee; Johnson Service Company, Johnson; Packard Motor Car Company, Packard; Stegeman Motor Car Company, Stegeman; KisselKar Company, KisselKar; American Automobile Company, Pierce-Arrow; Bates-Odenbrett Automobile Company, White.

PLANS FOR BOSTON'S FIRST TRUCK SHOW.

INDICATIVE of the rapid development of the commercial vehicles is the separate display of business wagons which will be held in Mechanics' building, Boston, March 13-20. Until this year trucks have had a place in the pleasure car exhibit, but the progress of this branch of the industry has necessitated a separate show, the demand for space upon the part of the manufacturers leading the Boston Commercial Motor Vehicle Association to decide upon this step. The management is under the personal direction of Chester I. Campbell, as heretofore.

The unusually large attendance at the New York displays of commercial cars is a forecast of the success of the Boston event and it is anticipated that the Mechanics' building will be taxed to its utmost to accommodate the numerous designs. Many makers who were unable to secure space at the metropolitan shows will be represented at Boston. The entry list includes all types of commercial vehicles from the tiny parcel delivery wagon to the 10-ton truck, and machines designed for every industry will be represented, as well as automobiles for municipal service. The result of the careful study and experimentation of the manufacturer during the past year will be revealed in special bodies constructed to meet every requirement and these will include dumping bodies which are operated by the driver without the latter leaving his seat.

Attractive Exhibit of White Trucks in the Foreground of the Commercial Vehicle Display at Providence, R. I.

The rapid development of mechanically propelled fire apparatus will prove interesting to municipal authorities and as a large number of different types will be exhibited these will attract those considering the displacement of the horse drawn equipment. Army wagons, ambulances and omnibuses will be found in large numbers as well as numerous types of vehicles especially designed for light delivery work.

Not only has progress been made by the manufacturer in the refinement of body designs but a great many improvements in the mechanism of the machines will be noted. New ideas in transmission will be exploited as well as many ingenious devices, all of which make for reliability and economy.

The commercial vehicle show will be a splendid object lesson, and the business man will recognize the value of its economic side, to say nothing of the worth of the automobile in service. The indications are that the power wagon show will share equally with that of the pleasure car event in the matter of attendance and business transacted. That New England is a promising field for the development of the commercial car is recognized by the manufacturer, and the Boston show will afford him an opportunity to demonstrate the superiority of the automobile over the horse drawn equipment.

TOLEDO'S THIRD ANNUAL DISPLAY.

The commercial vehicles were shown with pleasure cars at the third annual exhibit of the Toledo Automobile Dealers' Association in the Terminal building, Toledo, O., Jan. 15-20. The exhibitors of motor trucks follow:

Atwood Automobile Co., Overland, Garford, G. M. C., Federal; Banting Machine Company, Grabowsky; Rambler Motor Sales Company, Detroit electric; Northern Ohio Motor Car Company, Brush; Blevins Auto Sales Company, Gramm; United Motor Toledo Company, Sampson; Roberts Toledo Auto Company, Ford; H. J. Adams, Reo; Grasser Motor Company, Lauth-Juergens; Shop of Siebert, Siebert; McCreery Manufacturing Company, Oliver; James P. Locke, Adams; Morrill Company, Kelly.

OPEN AIR EFFECT AT PROVIDENCE.

The State Armory in Providence, R. I., was utilized by the Rhode Island Licensed Automobile Dealers' Association for its revival of motor car shows in that state, Jan. 22-27. It is four years since the people of Rhode Island had opportunity to inspect the different models in an exhibition of this character, but this was the first attempt to hold a display under the direct management of the association. Its splendid success presages an annual event in the future. The decorations were such as to give the impression of an open air park, in which the vehicles were displayed with splendid effect. Much business was transacted through the week.

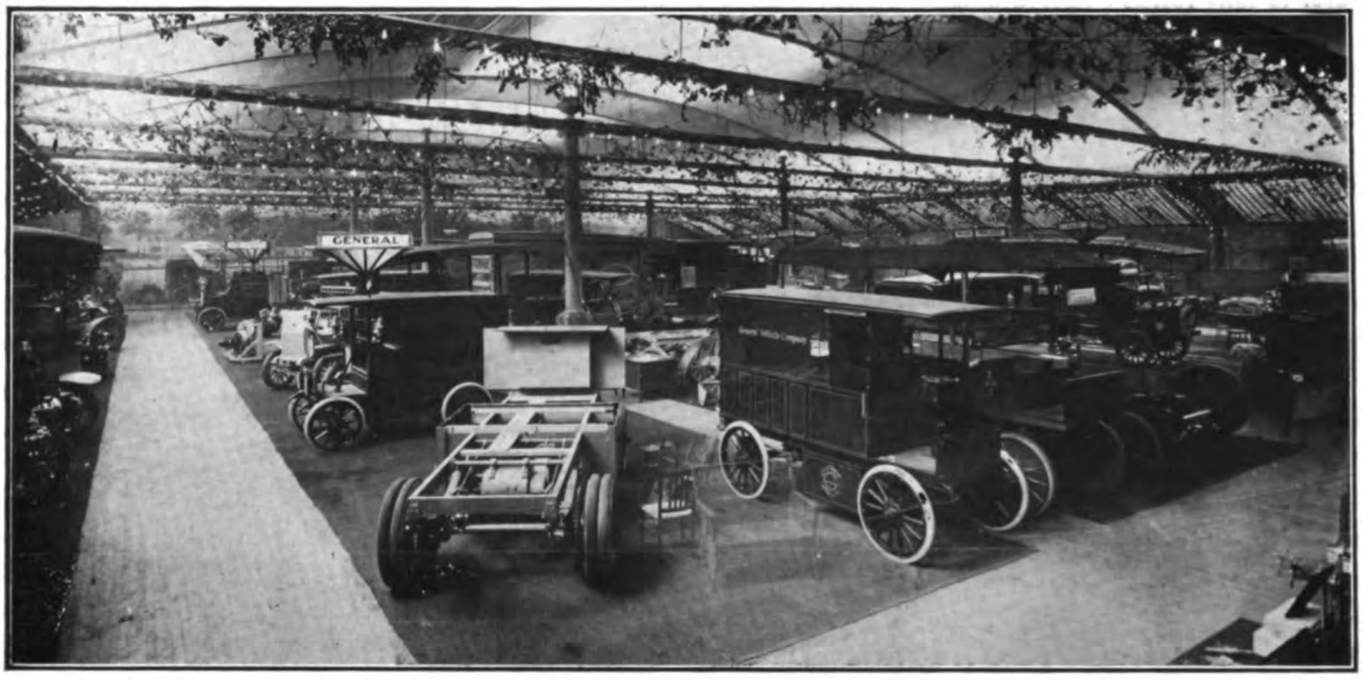
Those who made display of commercial vehicles were: White, Binford & Robinson Motor Car Company, White; Hitchcock-Banks Motor Car Company, Knox; Foss-Hughes Company, Pierce-Arrow; KisselKar Company, KisselKar; William Hughes Company, Reo; North End Garage, Chase; Pugh Bros., Morgan; American Locomotive Company, Alco; Autocar Sales & Service Company, Autocar; Alvan T. Fuller, Packard; B. F. & A. W. Hopkins, International Harvester; Davis Automobile Company, Gramm; Rhode Island Motor Car Company, Pope-Hartford; Teel Manufacturing Company, Teel-Woodworth.

EXHIBIT OF DETROIT DEALERS.

While trucks were shown in connection with pleasure cars at the annual display of the Detroit Automobile Dealers' Association, in the Wayne Gardens and annex in that city, Jan. 20-27, they made a most creditable impression. Inasmuch as the original structure was found too small to accommodate all who wished to make exhibit, permission was received for the erection of a temporary annex.

The following displayed power wagons: General Motors Truck Company, G. M. C.; Commerce Motor Car Company, Commerce; Ford Motor Company, Ford; United Motor Detroit Company, Sampson; Neumann-Lane Company, Pierce-Arrow; Havers Motor Truck Company, Havers; Motor-Wagon Sales Company, Motor Wagon; American Steam Truck Comany, American steam; Poss Motor Car Company, Poss; Grabowsky Power Wagon Company, Grabowsky; Seitz Motor Truck Company, Seitz; Durant-Dort Carriage Company, Best; KisselKar Company, KisselKar.

Digitized by Google



TWO BUILDINGS FOR PHILADELPHIA.

For the second time in the history of automobile shows in Philadelphia, a separate week was devoted to the display of commercial vehicles in the First and Third Regiment Armories, Jan. 22-27. In the former building the trucks shared the space with electric pleasure vehicles, and in the latter with accessories. The interior of each was handsomely decorated, and the fullest opportunity was afforded those who desired to inspect the mechanical features.

The makes shown in the First Regiment Armory were: Autocar, Brush, Cartercar, Commer, G. M. C., Gramm, Kelly, Mercury, Morgan, Peerless, Sandusky, Seitz and Speedwell. Those in the Third Regiment Armory were: Chase, Walker, Waverley, Mais, Commercial, Sampson, Pierce-Arrow, Alco, Knox, Packard, Reo, Philadelphia, Ford, Lozier, Baker electric, Cameron, Mack, Saurer, Locomobile, White, KisselKar.

WILL HANDLE COMMER TRUCKS.

Announcement is made by Wyckoff, Church & Partridge, Inc., New York City, that an agreement has been entered into with the Transportation Sales Company of that city which involves the purchase by the latter concern of Commer and Guy Vaughan cars to the extent of over $1,000,000. The new company will operate from the present location of Wyckoff, Church & Partridge, Inc., the latter retaining space in the same building for its general and executive offices. The plans of the new concern include the erection of a six-story building, in which will be installed a complete repair shop and service department. The structure will also include a large public truck garage with spaces and accommodations for at least 200 machines. A feature of the service will be an agreement to maintain free of charge for one year all repairs to Commer vehicles, tires and accidents being excepted. The Transportation Sales Company is composed of experienced automobile men and engineers fully capable of dealing with the New York situation, and its taking up the sales of Commer cars is in keeping with a plan outlined some time ago by representatives of the English product.

Interior of the First Regiment Armory During the Progress of the Power Wagon Exhibition at Philadelphia.

LUBRICATING THE COMMERCIAL CAR.

Inasmuch as the business world is rapidly recognizing the economy effected by commercial motor transports, it is essential to consider the matter of providing safeguards against delays and repairs to the vehicles which are called upon to perform such efficient and constant service. Operators of motor trucks sometimes are inclined to under estimate the attention necessary to be given to the mechanical features. There isn't the same "pride of appearance" feeling that exists with the chauffeur of a pleasure car, and as a result the entire truck may be made to suffer from inattention.

It is generally accepted that two-thirds of motor troubles, for instance, are caused by improper lubrication. This is a decidedly important consideration, inasmuch as the engine of a commercial vehicle is called upon to undergo heavy duty service throughout its entire life. It follows that it must necessarily possess wearing qualities, which cannot be retained without the very best lubrication, and in this respect the most satisfactory insurance against possible engine trouble is the proper selection of oil. It is poor economy to employ an inferior grade, simply because it is offered for less money.

Those who have made a careful study of the subject are agreed that the proper oil for motor truck lubrication should have, first of all, the right body or viscosity, and this must be such that it will not be affected materially by temperature changes. From the high heat of the cylinder to the lower in the crankcase, it must maintain a uniformity of flow and, at the same time, its lubricating qualities. It must have a fire test that will permit it to burn up cleanly after it has performed its function, and this cannot be accomplished if it contain free carbon. This latter can be removed only by a process of mechanical filtration which is expensive.

While there are oils on the market that will perform properly the services called for in a motor truck, the Havoline Oil Company, New York City, recently concluded practical working tests, which have resulted in the offering of a new brand under this well known firm name, to be known as Havoline motor truck oil. In the preparation of this, special attention has been paid to securing all of the qualities necessary for commercial vehicle lubrication. The guarantee of the Havoline concern should be sufficient to indicate that it is a satisfactory product for all requirements.

At the shows a very novel souvenir was given away at the Havoline booth. It consisted of a jig-saw puzzle which, when put together, portrayed an aeroplane, automobile and motor boat. When the puzzle is solved and delivered to one of the stations of the Indian Refining Company, 17 Battery Place, New York City, distributor of Havoline oils, the possessor is entitled to a valuable book of tours, compiled by an authority.

SALES METHODS WHICH SECURE REORDERS.

By P. D. Wagoner, President General Vehicle Company.

ONE of the most encouraging features of the motor truck industry of today is the increasing number of large orders received by manufacturers. These indicate in a substantial way a recognition of the value of the commercial vehicle and a confidence in the present day product. Furthermore, as many of these large reorders are from consistent users of the truck or wagon in question, they indicate also that the customer is convinced, after a practical test, that his inital motor truck investment was a paying one.

Almost before we have had time to realize the keen, nation-wide interest in the motor truck many of our large firms are saying among themselves, not—"Shall we 'try out' a truck?" but—"How many trucks shall we buy?" There are many phases to this question of buying trucks in quantities, and I have always watched "first installations" with much interest.

It seems to me that other things being equal the size of the first order depends largely upon the ability of the buyer to fully realize on his investment. If the buyer is a large corporation with a well organized transportation department such as is common to our great express companies, department stores, packers, brewers, etc., a sudden and radical change can more safely be made in the method of delivery, because the organization is in a position to cope with the new conditions and requirements which arise. With the smaller buyer this is not always true and some caution in buying is necessary in order to avoid confusion and unnecessary expense in operating power vehicles. I believe all broad-minded business men will concede the fairness of this suggestion.

P. D. Wagoner, President General Vehicle Company.

The transition from the centuries-old method of horse and wagon delivery to the 20th century method of motor truck delivery should here be done systematically and step by step if real efficiency and economy are to be secured and maintained. Motor trucks should not be measured by horse wagon standards. And what is more important from an efficiency standpoint, the system behind the loading and routing of horse drawn wagons should be wholly reorganized and the pace accelerated when the faster and surer power vehicles, independent of weather and of flesh and blood limitations, are substituted.

With perhaps 40 per cent. of our output to date or, specifically, 1000 vehicles distributed among less than 100 customers, our reorder experiences have been very extensive. Over 69 per cent. of our 1911 output went to customers already using our vehicles. We attribute our success in selling fleets, or in getting reorders, which is the same thing eventually, to our policy of selling most of our customers, first, a nucleus to work with and to build a foundation, and, then, when they have thoroughly tried out, say from two to 10 cars and readjusted their delivery system to meet the changed conditions, putting in our vehicles in fleets and from 10 to 25 at a time until their existing transportation needs are comprehensively supplied.

Large orders can best be secured on a basis of mutual confidence, patience and co-operation. I believe the reason we do not have larger motor fleets in some lines of trade today is because in the too frequent ambition to sell a customer as many trucks as possible in the shortest space of time, due consideration is not given to the needs of his particular business in his particular locality or environment. If the selling organization interested would study to give each customer just the truck or wagon or the number of each which he needed at that stage of his conversation and facilities, we should see more satisfied customers at the outset and larger reorders later on. Progressive expansion is what is needed—not a wasteful upheaval of a delivery structure developed through years and years of gradually increasing business.

On the other hand the great truck fleets in successful operation today—and by the word "successful" I mean dividend-earning—are but a handful of what we will see in less than another decade. Shrewd, far-seeing business men are more and more being converted to the use of the motor truck and just in proportion to the proven value of the first, perhaps, very modest installation will their confidence grow and will they reach for their pen to sign reorder contracts. Hysterical, "hurrah boys" methods may sell pleasure cars to care free recreation seekers, but they are out of place in selling business cars, just as slipshod methods are doomed to failure in building business cars.

Motor truck reorders are inevitable with large firms provided the trucks first purchased—but still on trial from an operation viewpoint—are well built and adapted to the work involved, and the sales department handles the matter of additional trucks intelligently and in a spirit of fairness to the buyer. But create the impression, by over enthusiastic order takers, that the purchasing agent must go to his superiors and ask them to let him practically scrap, at once, the rest of his horse and wagon equipment and you may have retarded sales indefinitely.

We have given much thought to this matter and have doubtless lost many sales by waiting until in our opinion a customer has had time to balance his ledger and show a profit from his first small installation, just as we have lost sales by declining to build special trucks which we knew would prove impracticable and eventually dissatisfy the customer. On the other hand we have in some cases made a lasting friend for our product by counselling the too ardent convert to electrics to go slow and to order trucks only as fast as he could economically use them to supplant other equipment.

All of which emphasizes a growing impression among some truck manufacturers who have been building trucks for 10 years or so that selling motor trucks is a science in itself and that the most brilliant pleasure car salesman may sell but a few trucks and these to his firm's sorrow.

This is why I believe that sound engineering principles and workmanship evolving a standardized product, combined with intelligent co-operative sales methods will produce the bulk of motor truck reorders in the future.

UNITED STATES TIRE DATA.

Information relative to the tire problem is always of interest to the user of the commercial vehicle and prospective purchaser as well. An unusually attractive booklet has been issued by the United States Tire Company, New York City, and the brochure describes and illustrates in detail the new United States standard tire and demountable rim, which is manufactured for single or dual tread. This device permits of the removal and replacement of a shoe easily, thereby saving considerable time. Accompanying the booklet, which is printed in colors, is a card giving the standard tire and wheel dimensions for demountable and non-demountable solid motor tires adopted by the Society of Automobile Engineers, also the general dimensions of the product of the United States Tire Company.

LA FRANCE GASOLINE-HYDRAULIC TRUCK.

Five-Ton Vehicle in Which the Clutch, Sliding Gears, Jackshaft and Differential Are Eliminated by the Use of the Manly Patent Transmission, Which Has Remarkable Flexibility and Greatly Multiplied Power.

THE use of a pump in which oil is the circulating medium, and the utilization of this pump by varying its capacity instead of changing the speed of the motor by which it is driven, this pump taking the place of the conventional gearset or transmission mechanism, is the feature of the La France gasoline-hydraulic truck. This machine is built by the American-La France Fire Engine Company, Elmira, N. Y., and the device is employed under a license for the patents granted to Charles M. Manly. The system is known as the Manly hydraulic transmission, which is an adaptation of the pump instead of gearing, the pump in turn driving oil through a construction termed motors, which are really actuated by the circulation of the oil, and these motors turning shafts on which are sprockets, from which chains transmit the power as with any normal form of side chain drive to wheels revolving on a dead rear axle.

It will be seen that the construction as it is in these trucks eliminates the usual form of clutch, change gearbox, the drive shaft, the jackshaft and the differential. The power delivered at the traction wheels is dependent upon the flow of oil through the motors, which are of the cylinder and piston type, and this flow is varied by changing the length of stroke in the pump cylinders from zero to the fullest capacity. With the usual form of power reduction by change of gear ratio there are distinct steps, ordinarily three in a forward movement, and but one for a backward movement of the vehicle. It is true there is a considerable variation possible in the engine speed, but when running slowly the motor does not develop its normal power, and to race the motor means deterioration. The hydraulic drive is intended to afford a constant engine speed and utilization of the full power at whatever ratio may be necessary to obtain the desired vehicle movement.

In connection with this form of power transmission it might be said that it is in effect a parallel of steam in that there need be no gradations of increase or reduction. One of the greatest qualities of the steam engine is that the precise power needed for a work may be exerted to the maximum capacity, the only effect of an overload with a steam engine being to stop it, just as gravity will overcome velocity when a cannon ball is projected into space. Any steam engine of good design will withstand an overload of from 50 to 200 per cent. for a limited period, and from the imaginary nothing to this extreme any power may be used. This power is dependent upon the engine speed. With the gasoline motor reasonable movement must be obtained to develop power and between the points where efficient energy is developed and where there is no possibility of damage, let us say from 800 to 1200 revolutions, for example, is the range of variation. This is as broad as good practise would dictate. It will serve for illustration, however. Between these points the engine may be varied, but to obtain an ideal it ought to be maintained at 1200 revolutions, we assume. Were this done we would have simply the three speed steps, which we will further assume to be one-third and two-thirds of the engine speed and direct drive. There would also be the reverse of one-sixth engine speed. To get wider power variance we accelerate or lessen engine speed, with consequent variation of power in a far different manner than might be assumed. To apply the power slower we increase the leverage through gearing, and when used this leverage relieves the engine of a part of its load and it will increase its speed materially. With lessened vehicle speed the motor speed is generally increased and the motor will acquire speed as its load is diminished or the leverage is increased by gear reduction. But under any circumstances the work is by steps or within certain limitations which do not obtain with the steam engine.

The La France Five-Ton Truck in Which the Manly Hydraulic Transmission Takes the Place of the Conventional Driving Mechanism.

Steam has enormous expansive force and great elasticity. Fluids cannot be compressed and therefore have little elasticity, but it is possible by forcing them through orifices of varying proportions, as from a cylinder by a piston, to produce a cushioning effect that may be estimated with great exactness and to cause certain results. For instance, in the utilization of this principle the recoil of heavy naval guns has has been entirely absorbed and shocks of tremendous force very largely eliminated, or at least brought well within the limitations of the gun mounts. This has been accomplished by a system of cylinders filled with glycerine in which are plungers or pistons. In the pistons are series of channels or grooves that are tapered with the smallest end nearest the muzzle of the cannon. As the

Digitized by Google

gun is fired the mount is driven backward and against the cushion of glycerine by the recoil. The fluid is forced into the grooves and flows toward the other end of the piston, but as the volume that will pass from the smallest ends of the grooves is dependent upon the force of the recoil, and as a greater quantity of glycerine will enter the largest ends in a given time than can flow through the smaller ends in the same period the impact of the explosion is sustained upon the glycerine. The fluid begins to pass through the grooves as the piston moves and as these constrict the velocity of the flow increases but the volume is no greater. The impact or shock is at maximum when the piston begins to move and as the piston moves backward its velocity decreases gradually until it stops. It is possible to compute with a certainty every factor entering into construction and operation of such a device.

With the hydraulic transmission as constructed under the Manly patents the principle of the recoil absorbing device is reversed. It may be defined as a system of pumps, motors and piping which is filled with oil. The pumps force the oil to circulate through the system and the rapidity of movement of the motors is dependent upon the velocity of the circulation of oil. The motors must be of maximum capacity and for that reason the power generated is absolutely dependent upon the speed at which they are driven. The slightest movement of the oil must have an effect upon the motors. The impulse may be made by the passing of a very small quantity of oil through the motor, and the shafts may turn but a single degree, but this impulse has a positive power value and a definite force.

As it is regarded as imperative that the vehicle engine should be driven at or as near a constant speed as it can be adjusted to develop a given power, and as the oil motors must have a stated capacity, the flow of the oil is not varied by the speed of the vehicle engine but by varying the capacity of the pumps. The pumps must have variable capacity, and as a series of pumps would result in establishing power steps as with a gear reduction, this variation has been obtained by changing the stroke of the pump. It is possible with the Manly system to adjust the pumping pistons so as to pump any desired volume of oil through the motors, from a fraction of an ounce to piston capacity, so that while the vehicle engine may be driven at a given velocity and the pumps to an exact number of revolutions each minute, the circulation of the oil may be theoretically from zero (and practically nothing) to a maximum volume, or even reversed.

It is well enough known that gases may be compressed to liquids, but not beyond that point. Under some conditions in the use of the motor wagon it may be necessary to stop quickly, in fact to stop the pumping of the oil circulation. This would mean stopping the motors and there would necessarily be increase of the pressure in them. This has been compensated by a valve that will open when the pressure of the oil has reached 2000 pounds to the square inch, and the oil will flow through this until the pressure falls below 2000 pounds. The normal pressure forcing the oil circulation is estimated to be 400 pounds, so that when this has been increased five times the safety valve releases the excess and there will be a slight movement of the motor corresponding to the difference in the pressure upon the oil, but the excess oil is thus passed from the regular circulating system around the motors to another point in the system between the motors and the pump, thus practically equalizing the pressure to 2000 pounds or less. It might be pointed out that while these pressures have been fixed upon as giving a satisfactory result these may be changed to meet any requirement. They may be less or more or with differing relations, but in practical service these figures have been established as meeting such conditions as might arise.

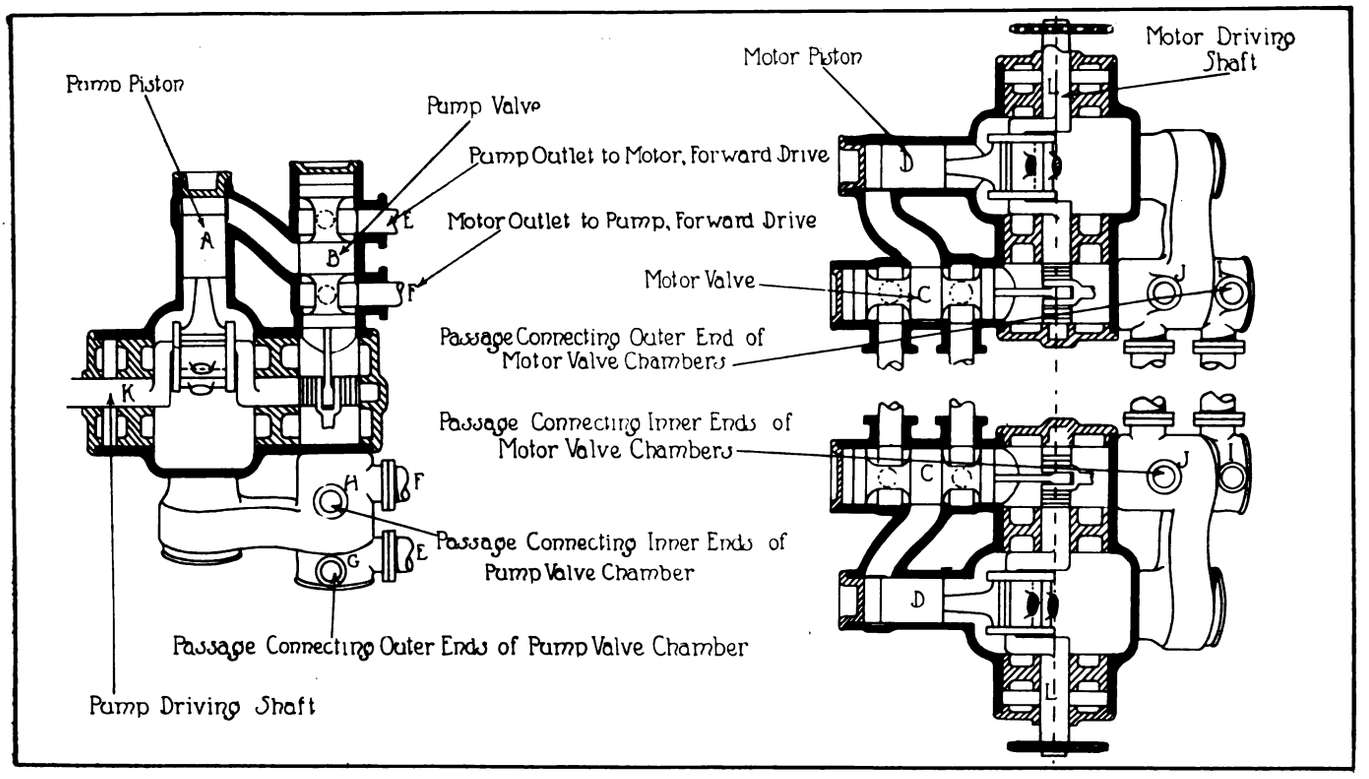

Fig. 1—Drawing Showing the Manner of Installation of the Hydraulic Transmission System, the Pump Transverse of the Chassis Frame and the Motors and Shafts Serving as the Conventional Jackshaft to Drive the Rear Wheels by Double Side Chains.

Reference has been made to the increase of power by slowly applying it by gear reduction, and with the Manly system there is a similar increase possible through the exercise of greater pumping capacity, for the pumps can be driven to the safety valve limit of 2000 pounds and the oil forced through the motors at that pressure. As the pumpage through the system may be varied at any pressure the motors may be made to move very slowly and with extreme power. Estimating this power to be in direct ratio to the increase in pressure in the oil system it may be regarded as 400 to 2000 (the limit allowed by the safety valve) or five times. With the engine running at a constant speed there is then the variation of oil circulation from zero to 2000 pounds to the square inch, which affords a margin very much in excess of all probable requirements.

Digitized by Google

In fact there is so wide a range that it parallels the steam engine for variability, elasticity or flexibility, for any one of these terms will fairly well represent the quality.

In considering the possibilities with this form of drive or transmission it may be well to contrast it with the conditions to be met with in the service wagons generally in use. This is with reference to the construction and the result of continued operation. Any shaft driven vehicle must have power transmitted through worm or bevel gears. There is a degree of friction transmitting power at angles that cannot be overcome. Without specifically detailing this frictional loss of power, which must be apparent in the new machine, there is no question that it is materially increased as the mechanism wears. This may be said to be begun at the motor itself, due to a perceptible degree to the irregular torque or movement of the engine, and this may be followed through the clutch, the transmission, the shaft and universal joints and the differential.

Theoretically a double side chain drive has the greatest efficiency so long as the chains are well cleaned and lubricated and the sprockets are not badly worn. But with the system that may have an initial efficiency of 96 (the maximum of expectation), the loss may be as high as 33 per cent., approximately. Of this about 10 per cent. may be attributed to universal joints with shaft driven machines. The remainder is to be distributed through the system. Contrasting the side chain driven types there is little probability that this loss will differ much with either form of transmission so far as the chains are concerned, but there will be a decided gain in the Manly drive because there is a minimum wear with a motor driven at constant speed, and there is the elimination of the clutch, the universal joint between the clutch and transmission, the transmission, the universal joint or joints of the driving shaft, and the differential gear of the jackshaft.

As the Manly system of pumps and motors operates in oil which at a pressure of 400 pounds must penetrate to and between every surface in frictional contact it will be seen that there is but little wear probable. Every moving part of the pumps and motors is constantly bathed in oil and the harder the work the greater the certainty of lubrication. There can be no failure of lubricity under any circumstances. There is in the Manly system eight gallons of oil in circulation in the pumps and motors.

The power required to move a load from a standstill is much greater than is required to draw or pull it. As is well known, it is easier to draw a load than to push it. That is why practically every form of transport is drawn instead of pushed along. With the motor wagon the vehicle is pushed and to overcome its anchorage a much greater effort is necessary to start. This is the reason for applying power slowly and obtaining greater leverage when starting a truck or wagon, changing to a higher gear ratio and lesser power application when the movement has been begun. With the steam vehicle the power is exerted slowly, from the imaginary nothing. With the conventional transmission the start is made on the low gear ratio. With this form there is more or less strain upon the engine and the engine cannot be driven to its greatest efficiency when the delivery of power is most needed. When the truck is loaded it must subject the power plant to the greatest stresses in starting and in climbing grades where it is necessary to change to a lower speed. With the Manly transmission the full power may be utilized at any time and under any circumstances, with the least strain upon the motor.

While the La France truck has abundant engine power - -it is rated at 48.4 horsepower by the S. A. E. standard - it may not be necessary to utilize but a part of this, and there is a reserve that may be applied when desired. The power is generated by a conventional gasoline fuel motor of the four-cylinder, four-cycle, vertical type. The cylinders have a bore of 5.5 inches and stroke of six inches, are of the Arriob type and are cast in pairs. The maximum speed is fixed at 1200 revolutions a minute. This engine is carried under a hood between the seats for the driver and the helper and it is cooled by a radiator at the front of the chassis, the water being circulated by a gear driven pump, and drafts from the fan mounted on the forward cylinder and driven by a belt from the camshaft extension, and from the fan-blade spokes of the flywheel. This statement is made to emphasize the fact that the truck has power that is at least equal to other vehicles of its class, aside from the fact that it has the qualities specifically stated. In other words, it is possible to utilize any degree of its engine power to the limit and then beyond this to the limitation of the oil motor system safety valve.

There is nothing in any way unconventional with the truck save in the transmission or driving system, which, while known to many engineers, is not generally familiar to those well versed in motor vehicle mechanics. For this reason a somewhat more detailed description is given, which is supplemented by three drawings, one of these being without reference to proportions and merely serving to illustrate the manner of installation of the transmission. It should not be considered as more than a suggestion at best.

By reference to this sketch it will be understood that it assumes a mid-section of a chassis frame, showing the end of the driving shaft that is coupled with the engine crankshaft. This driving shaft is carried in an installation or mount and coupled to this is the device that controls the oil pump. Examination of the illustration of the truck itself will show that this mechanism and the oil pump form practically one assembly that is carried between two cross members of the frame. The pump consists of a housing that shows the five cylinders in which the pump pistons

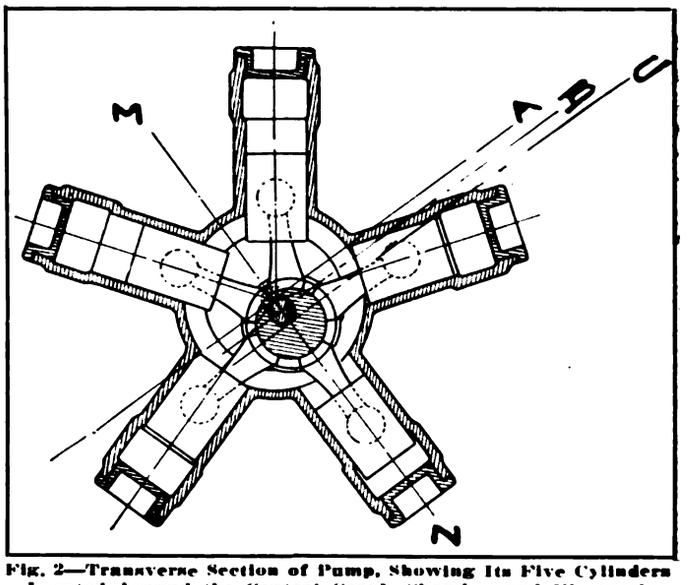

Fig. 2—Transverse Section of Pump, Showing Its Five Cylinders Located Around the Central Crank Chamber and Illustrating Method of Varying Stroke of the Pump Pistons.

or plungers are arranged radially with reference to the driving or pump shaft, and that paralleling these cylinders are the five valves or cylinders through which the oil is forced by the action of the pistons. In the operation of the pump each piston is in turn actuated as the driving shaft is revolved and the stroke being variable the oil is forced through the valve and into the piping to the oil motors.

Further examination of the illustration of the truck will show that there is at either side of the truck a single oil motor assembly, which are operated in unison, as the oil is normally pumped to each motor in precisely the same volume and speed. As the oil is forced through the oil motors it is carried back to the pump and while the truck is moving there is always a circulation of oil. It is possible, however, by circulating the oil from the pump around the motors to move the truck by turning the starting crank, or it may be pushed about the garage, for instance, by hand. Each oil motor has its own independent driving shaft and in turning a corner the motor at the outside will move more freely than that at the inside because of the lessened resistance, this condition being practically the same as might be found with a differential gear, though driven from the outside instead of the centre of a divided rear axle.

The pump is a decidedly interesting mechanism and it is possible to fairly illustrate it by reference to Fig. 2,

Digitized by Google

which is a cross section of the pump cylinders and does not indicate the valve system or the manner of oil circulation through the pump. It serves to demonstrate the method by which the length of stroke of the pump pistons is controlled. On the pump driving shaft is a bushing or sleeve and the connecting rods of the pump pistons are attached to this bushing. Referring to Fig. 2 it will be seen that the line M-N passes through the centre of the pump driving shaft, the centre of the eccentric crank of the pump driving shaft and the centre of the eccentric pump driving shaft bushing as they are shown in sketch. The line A intersects the line M-N in the centre of the pump and the centre of the pump driving shaft. This is also the centre of rotation. The pump driving shaft has an eccentric crank whose centre is shown where the line B intersects the line M-N, and the eccentric pump driving shaft bushing has a centre where the line C intersects the line M-N. The eccentricity of the bushing is equal to the eccentricity of the crank. That is, the line B is equi-distant from the lines A and C. This eccentric bushing can, at the will of the operator, be rotated about the eccentric crank of the pump driving shaft independently of the rotation of the pump driving shaft itself.

In the position shown the stroke of the pump is equal to the eccentricity of the pump crankshaft plus the eccentricity of the bushing, and is at maximum. If the bushing were rotated about the crankshaft through the angle of 180 degrees the line C would coincide with the line A, the bushing and the pump driving shaft thus becoming eccentric, so that the pump would have no stroke at all. The different positions between these two extremes give different strokes, and since any position of the bushing may be established, any stroke of the pump can be obtained, which, of course, means any speed for the pump, the motors and the truck. The rotation of the crankshaft bushing from the position of maximum stroke to no-stroke position is accomplished through the use of an auxiliary piston, lying parallel to the shaft, and supplied with power from the fluid pressure of the pump. The piston operates on the bushing through appropriate mechanism. It is under the control of a pilot valve which is actuated at will by a hand lever. Briefly the double-eccentric action makes possible the variable character of the pump stroke.

Referring again to the illustration of the truck it will be noted that there are two pipes between the pump and the oil motor, and through one of these the oil flows to the motor and through the other is returned to the pump. When the pump is reversed, and it has a reverse capacity of a quarter of its forward pumpage, the circulation is correspondingly changed. The oil motors may be operated to capacity in either direction and with equal power production, the only limitation being the pump.

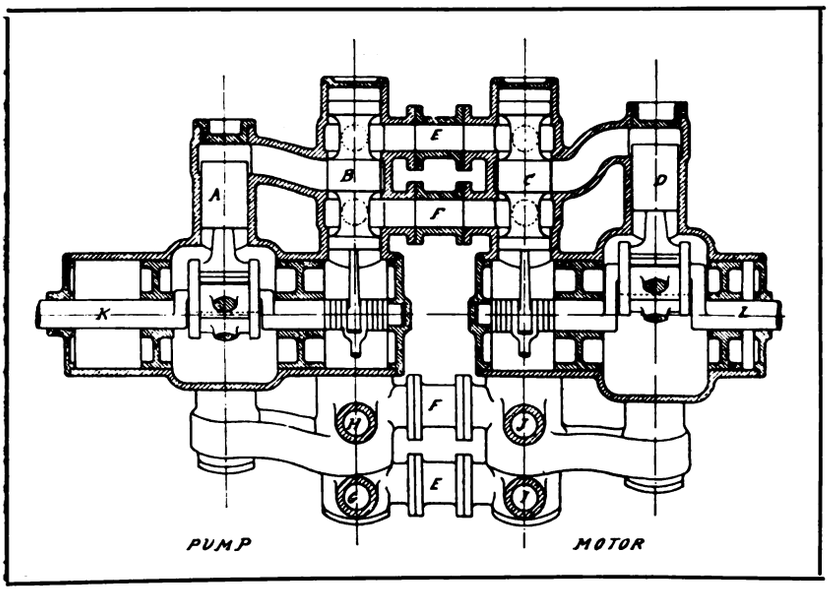

Fig. 3—Sectional View of Pump and One Motor Connected by Piping to Illustrate the Circulation of the Oil in the Manly Hydraulic Transmission.

For the further illustration of the system attention is directed to Fig. 3, which shows a pump at the left of the assembly and a motor at the right. These are not the positions they have in the installation in the truck, the vehicle illustration showing that the driving shaft of the pump is at right angles with those of the motors, the piping being of considerable length. This sketch shows, however, the cylinders and valves of both pump and motor and the pipes connecting them.

Considering this drawing it will be seen that A represents the pump pistons and B the pump valves. Passages extend from the head ends of the pump cylinders to the centres of the corresponding valve chambers through which the oil is forced by the pump strokes. C represents the valves and D the pistons of the oil motor, there being similar passages extending from the centres of the valve chambers to the head ends of the motor cylinders. The passages are connected by the piping, which is shown by E and F. One pipe carries the oil from the pump in the one direction, and after the oil has passed through the motor it is returned in the opposite direction. The outer ends of the five valve chambers of the pump are connected by the circular passage G and the inner ends of the chambers by the circular passage H, and in a similar manner the outer and the inner ends of the five valve chambers of the motor are connected by the circular passages I and J. K represents the driving shafts of the pump and the motor. The motors are identical with the pump save in variable stroke and size. This operation as illustrated is for the regular or forward movement of the pump. For reversal the pump stroke is first passed through the zero point of the stroke and then the valves change and the oil is simply pumped in the opposite direction through the ports and the piping of the motors.

When the motors are driven forward the pipe E supplies the motor with the oil forced by the pump, while the pipe F returns it to the pump from the motor, thus answering the purpose of an exhaust pipe. When the pump is reversed and the motor is driven backward, the pipe F becomes the supply pipe under pressure and the pipe E becomes the exhaust pipe, the direction of the circulation of oil through the connecting pipes becoming completely reversed. Should there be a sudden change in the speed of the vehicle or the pump quickly reversed the momentum of velocity in one direction is taken up by the transmission system. That is to say, the pump being idle the oil resists the movement of the motors to a pressure of 2000 pounds, when the bypass valve will be opened and the oil will then flow beyond the motors, but not through them. Naturally this resistance to movement is as strong a brake as is the movement of the engine a source of energy.

In this system no definite statement has been made as to the maximum power that may be exerted by the vehicle engine. It is a perfectly established engineering law that by hydraulics any force can be multiplied any number of times, but the greater the resultant force the slower the movement. With the La France truck 6500 pounds has been determined as the maximum tractive effort that can be employed without undue stresses upon the vehicle itself. This was determined by a test in which two spring scales were attached to the rear end of the truck and to a stationary object. The truck engine was started very slowly and the pump action reduced. When each scale indicated 3250 pounds the pressure of oil was such that the bypass valve was opened and the fluid was circulated with the truck at a standstill. The valve had been set at 2000 pounds. This test having established a satisfactory margin the standard of pressure was adopted as 2000 pounds, for this cannot be exceeded by the operator and there can be no possible damage when this pressure is reached. The actual maximum is the bursting point of the piping and the pump and motors. The tractive effort always available is sufficient to carry the truck, weighing 8000 pounds, with a load of 12,000 pounds, a total of 20,000 pounds, up a 14 per cent.

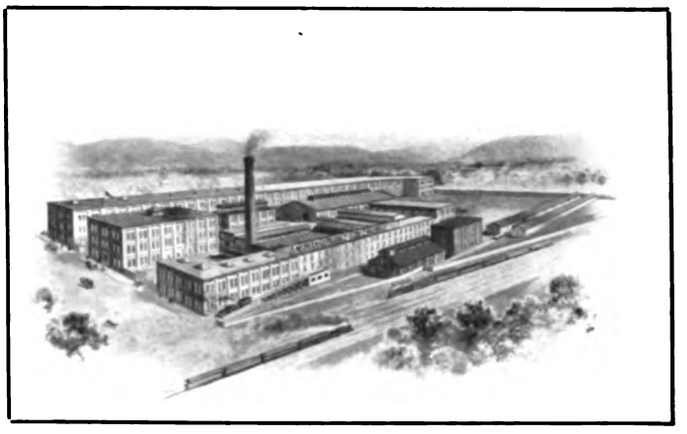
Digitized by Google

grade with snow hub-deep. It will be seen that this capacity is equal to any demand that might be expected, and far more than would be required in the conditions for haulage usually met with.

Now as to the efficiency, the makers will guarantee that this will be 87 per cent. of the useful power developed by the vehicle engine. A series of tests were conducted by George H. Barrus, an independent consulting mechanical expert, under four different conditions. These were as follows: Series A, with the circulating oil at medium temperatures, the driving shaft supplying constant power at constant speed, the driven shaft receiving constant power at varying speed; series B, with the circulating oil at medium temperatures, the driving supplying varying power at constant speed, the driven shaft receiving varying power at varying speeds; series C, with the circulating oil at maximum temperatures, the driving shaft supplying constant power at constant speed, the driven shaft receiving constant power at varying speeds; series D, with the circulating oil at maximum temperatures, the driving shaft supplying varying power at constant speed, the driven shaft receiving varying power at varying speeds.

Series A tests at 363 revolutions a minute of the driven shaft gave 85.3 per cent. efficiency; 250 revolutions gave 89.4 per cent., and 140 revolutions 85.7 per cent. Series B tests at 352 revolutions gave 86.2 per cent., 264 revolutions gave 88.4 per cent., and 112 revolutions 83.1 per cent. Series C tests at 350 revolutions gave 87.4 per cent., 270 revolutions gave 91.9 per cent. and 163 revolutions 87 per cent. Series D tests at 350 revolutions gave 87.4 per cent., 245 revolutions gave 90.9 per cent., and 105 revolutions 81.6 per cent. In these the highest number of revolutions may be regarded as maximum. Naturally the highest efficiencies were when the circulating oil was most heated and consequently more fluid. The efficiency ranged from 81.6 to 91.9 with the transmission, the average being 86.8.

There are many elements that make for economy entering into the use of this form of transmission. The constant speed motor is the most economical form that can be used, and with this type it is possible to use other and less expensive fuels, such as kerosene or even heavier hydrocarbons. Besides this it is possible to control such form of engine without spark adjustment and there need be no carburetor adjustment other than at the carburetor itself. This eliminates all control elements to the lever by which the transmission pump stroke is varied, which is located on the steering column. By the movement of this lever the truck may be handled to the fraction of an inch, a matter of extreme importance when space is limited. As a matter of fact a governor which will eliminate any other control is recommended by the builders. By merely turning the engine crank the transmission pump is transformed into a hydraulic jack of enormous power. This may be utilized if necessary to move the car. It is also possible to lock the two driving shafts of the motor so as to cause equal tractive effort with both rear wheels. The truck may be operated by the man who knows nothing about conventional forms of transmissions. Every complication so far as the driver is concerned is eliminated.



As a matter of fact the truck may be driven at all four wheels by this form of power if desired, and this power may be also utilized to steer the vehicle, and for hoisting dumping bodies, etc.

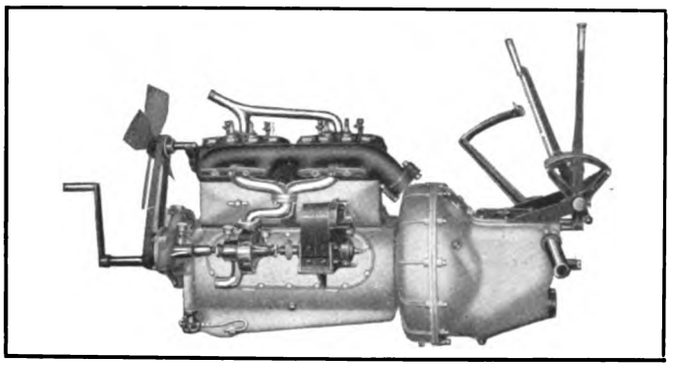
The other details of the truck are interesting because the construction is designed for especially heavy work. While normally rated at five tons it is held that it will safely stand an overload of another ton. The deck of the truck is 14 by six feet, giving 84 square feet of loading space. The platform is four feet above the ground when unloaded. The overall length of the truck is 18 feet 11 inches and the width seven feet 2.5 inches, with wheelbase of 143 inches and clearance of 12 inches. The overhang of the body is five feet three inches. The tread is 66 inches forward and 68 inches at the rear. The turning radius is 45 feet. The weight of the chassis is four tons, the maximum speed forward is 12 miles an hour, and the maximum reverse speed is three miles.

Some detail has been given concerning the vehicle motor which has force feed lubrication to the bearings and splash for the engine interior. The ignition is by Bosch magneto, dual, with fixed spark. The radiator is of the cellular type. The gas is ordinarily controlled by a foot accelerator.

The chassis frame is of pressed alloy steel channel section 9.5 by three inches by 18.75 inches, not trussed, but is built with numerous cross members and heavy gusset plates. The springs are semi-elliptic, 42x3.5 inches forward and 48x3.5 inches rear. The rear axle is dead, three inches, square section; the front axle is four by 2.5 alloy steel I section. The wheel bearings are Timken roller. The wheels are of wood, artillery type, and the tires are the Kelly-Springfield sectional, 36 by five forward and 38 by nine rear. The radius rods are 2.5 inches in diameter alloy steel. The emergency brake is expanding on the rear wheel drums and is operated by a lever at the right side of the driver. The gasoline tank capacity is 22 gallons and the oil capacity a quart.

The principle of the transmission is not new, but its application is. The first device of this character used was installed in a two-ton wagon in January, 1907. This vehicle has been used for demonstration purposes and yet no changes or repairs have been made in the transmission during the period of service. It has been driven more than 8000 miles with no load of less than two tons. The Bethlehem Steel Company is building 62 of these transmissions, for use on the new 28,000 tons Argentina battleships for turret turning and gun pointing. The system is covered by eight patents and 20 applications that are pending, all being owned and controlled by the Manly Drive Company, New York City. The American-La France Fire Engine Company, which has been for more than 35 years one of the best known builders of fire apparatus in the country, is building these trucks under license. The Hydraulic Truck Sales Company, New York City, has been organized and incorporated to market this production.

Plant of the American-La France Fire Engine Company, Elmira, N. Y., Where the Hydraulic Truck is Built.



"TRUCKS RELIABLE," SAYS WILLYS.

"The commercial vehicle has reached the advanced development of the pleasure automobile," says John Willys, president of the Willys-Garford Sales Company, distributor for Garford commercial and pleasure vehicles, "notwithstanding the fact that some are of the impression that the business wagon has not progressed as rapidly as the lighter car. This is due, in a measure, to the fact that the former has not participated in as many spectacular contests. The early experiments of the power wagon were in the nature of private tests, but were, nevertheless, more exacting than those of the other type of machine. To prove that the commercial vehicle could withstand as gruelling a strain as the highest type of pleasure car, they have accompanied the latter in tours and endurance contests as baggage carriers, and in these runs performed consistently, maintaining the schedule of the other machines. The business wagon of today is so reliable and rugged and trustworthy that it will carry its load anywhere. There is no question that the motor truck has arrived."

NEW HAZARD MOTOR CATALOGUE.

The new catalogue issued recently by the Hazard Motor Manufacturing Company, Rochester, N. Y., will appeal to

Unit Power Plant Produced by the Hazard Motor Manufacturing Company.

automobile engineers as well as those interested in the subject of power plants. It is not only a beautiful piece of printing, but the descriptive matter fully gives in detail the construction of the Hazard motor. The book is unusually well illustrated, depicting as it does, different power plants for commercial vehicles, also the special reduction box on the rear end of and integral with transmission, a new feature for use on heavy cars utilizing shaft drive. This arrangement provides an additional reduction of 2.5 to one, although different ratios are made.

The accompanying cut, which is a reproduction, the first employed in the catalogue, depicts the complete power plant which consists of a four-cylinder, four-cycle motor with three speeds forward and reverse selective type of transmission, in one unit, connected by a multiple disc clutch of 16 hardened, tempered and ground steel plates running in oil, operating clutch and brake pedal. All specifications of the product of the company are fully illustrated, making it of value as well as interest to the reader. Copies may be secured by addressing the company.

FACILITATES LOADING LUMBER.

To make motor trucks profitable in the lumber industry long waits must be avoided while the material is being assembled. Where the loads consist of various sizes of lumber considerable time is consumed in making up the order. During this period the power wagon must be kept busy hauling, and to allow this a movable platform is utilized which permits of shifting the load from one vehicle to another, an operation which consumes but a few minutes.

In the accompanying illustration is shown the device employed by the Curtis & Pope Lumber Company of Boston which concern maintains a fleet of White cars, made by the White Company, Cleveland, O. One of these is depicted beside the vehicle fitted with the platform and the positions occupied, if the latter were to be transferred to the automobile.

While the power wagon is delivering the other vehicle is being loaded in the yards, being hauled by horses. When the car returns it is operated into position beside the loaded wagon and the load shifted. In order to carry long pieces of material the raised frame of the device is fitted with rollers, the forward member being elevated which permits the transportation of long beams as well as making easy their unloading. In addition the load can be balanced perfectly. The entire arrangement makes it possible to produce maximum results.

BILL TO LIMIT TRUCK WEIGHTS.

Those connected with the motor truck industry, as well as commercial vehicle users, will be very much interested in the outcome of a bill introduced into the Massachusetts Legislature, limiting the weight of automobiles employed on the highways. While the full text of the proposed legislation has not reached this office, it is understood that its provisions are such that it practically would prohibit the use of trucks of more than two tons capacity. There is little doubt that the public hearings on the bill will be attended by those who appreciate the value of modern transportation methods, and it seems hardly probable that Massachusetts will place the law on the statute books.

IMPORTANCE OF SERVICE STATION.

During an informal luncheon given by C. P. Coleman, president of the International Motor Company, New York City, in that city recently, at which were present heads of the various departments, agents, etc., Mr. Coleman spoke of the importance of the service station, its maintenance and the necessity of having competent trouble men and inspectors connected therewith. The address teemed with many interesting features pertinent to the commercial vehicle industry.

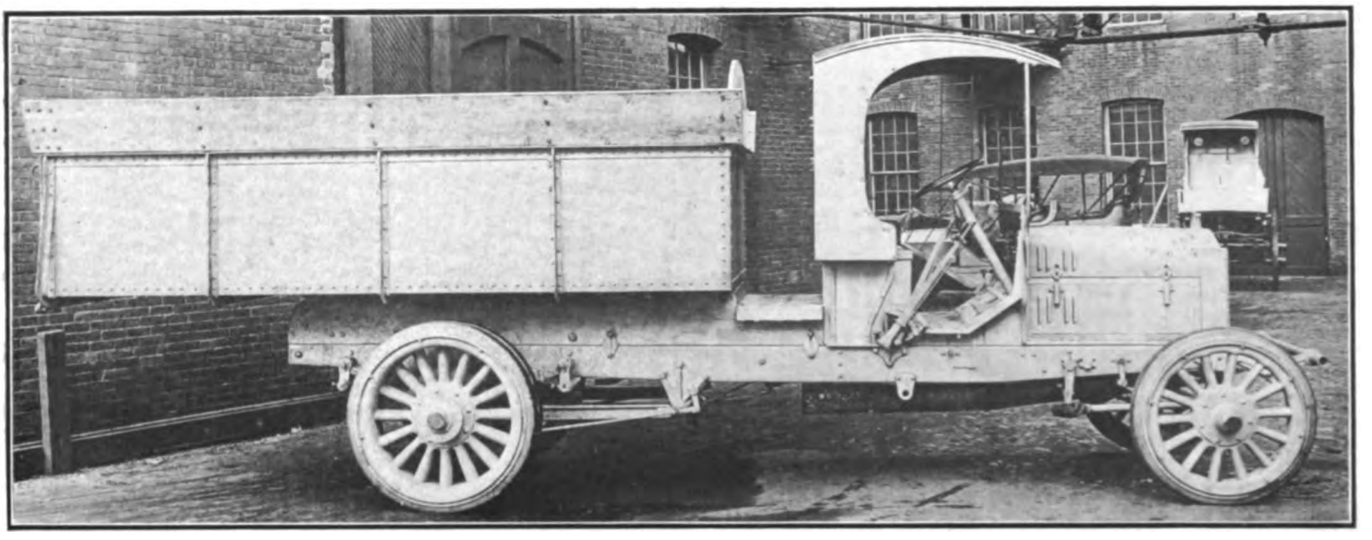
PRACTICAL MOTOR TRUCK BODY DESIGNING.

Sizes Regarded as Capacity Standards, from Which Estimates Are Made and the Differing Constructions Created—How the Components Are Specified and the Materials Are Selected and Prepared for the Assembling.



By William W. Scott.

THE acceptance of certain types of animal vehicles as standard, and then the manufacture, first of components and later of complete conveyances, created recognized dimensions that have been adopted generally. It is possible, for instance, to purchase all the parts necessary for practically any form of construction, even to fittings, hardware, and the like, so that a type of wagon or cart may be built or assembled by a hundred different workers and yet differ slightly, if at all. This condition had the effect of standardizing horse transports and this has led to the assumption that we must accept as fundamental the dimensions of these conveyances. Standardization is a manufacturing convenience and necessity, but what may be regarded as standard for one form of production may not be satisfactory, or even suited, for another.

In the construction of motor propelled wagons there are many conditions arising which are so radically different from those obtaining with animal service that one may express surprise that there has not been quite as great revolution in design as in power. In power wagon engineering different lines of effort have been followed and while these have been in practically every direction so far as mechanics are concerned, few have been bold enough to consider from a scientific viewpoint the matter of hauling loads without reference to animal conveyance design. It is true that highways and open areas for shipping and receiving, buildings and the like, have created or arranged for horse service, but the original adaptation of power plants to existing wagons has led to accepting these wagons and carts as the limitations for motor transports.

It is also a fact that with the advance of mechanical engineering as applied to automobiles there has been little attention given to spring construction or design, and while it is admitted that there is greater need of improved suspension and running gear there has been comparatively small progression. The increased speed, the greater stresses and heavier road shocks, have brought about heavier constructions, but there has been no especial change in form, as might be logical with a certain need of load equalization with reference to wheels, with need of minimizing the height of the centre of gravity of the load, and to insure against stresses on account of the careless arrangement of the load.

Just the proportions of the load and its location on the chassis must be problems for the designer to solve, and these must govern the form and size of the body and the weight that may be carried in it. It is obvious that chassis design differs widely. With some the construction is to bring as much as 33 per cent. of the freight weight upon the front axle, and this ratio may lessen until as much as 95 per cent. of the load is carried upon the rear axle. With some the centre of the load may be very close to the rear axle and, with others, even behind it. It is understood, of course, that the distribution means when the chassis is level and the load properly placed. It may be assumed that overloading may be permitted, but while it is not impractical to vary slightly from the capacity limit it is apparent that when the load of a power wagon is not equally distributed there is considerable more stress on the construction, at least a different stress, and with the increase in the height of the load these stresses are also multiplied.

Five-Ton Pierce-Arrow Worm-Driven Truck Equipped with Steel Body with Flare Boards for the Transportation of Coal—This Installation Has Capacity for More Than the Normal Load, But Can Be Used for the Haulage of Other Materials.

Low Centre of Gravity Necessary.

For this reason it is desirable to bring the centre of gravity of the load as low as it can be with the design. While the tread of the vehicle may be 72 inches with some machines, with few exceptions it is necessary to carry the body above instead of between the wheels, and to insure wheel clearance when the springs are compressed the body must be sufficiently high. The condition is much different than is experienced with the animal vehicle where the load may be carried on heavy dead axles and entirely between the wheels, without spring suspension that is susceptible to overloading. Overloading of the animal conveyance is generally responsible for wrecks, but the animals can and generally will stop when the work is beyond them. There is no indication of overloading with the truck unless it is the sagging of the springs or the appearance of the tires and for this reason the limit is made for weight of freight. The manufacturer of the chassis protects himself by a guarantee, as does the maker of the tires, and it is expected that the conditions against overloading shall be lived up to. Then it is essential that the owner of the vehicle shall for his own protection regard the limitations placed upon the

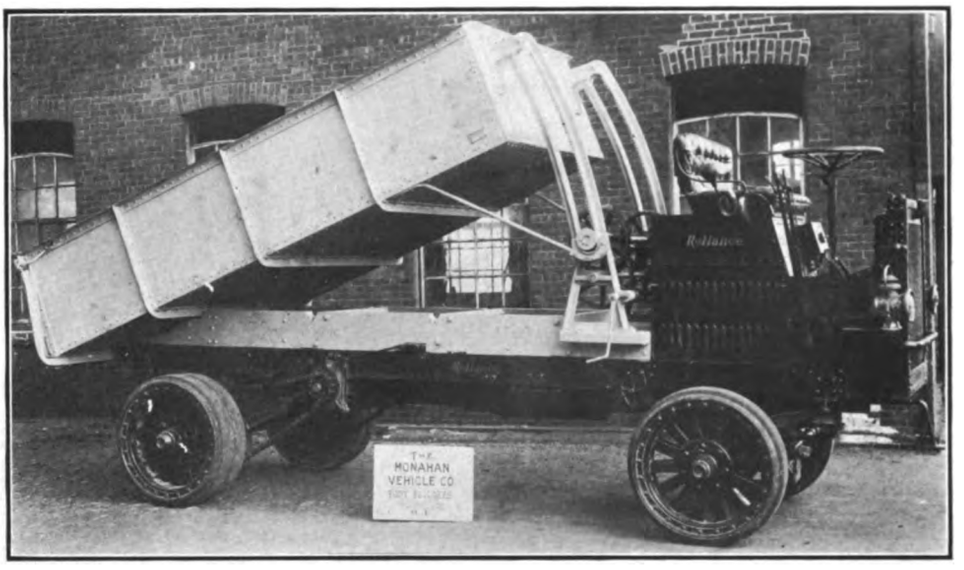
Digitized by Google

machine. It is obvious that were the construction such that 25 per cent. of the load were carried on the forward axle and 75 per cent. on the rear axle, a change from these proportions to 35 and 65 respectively would be dangerous. As loads will vary so much in weight it is impossible to produce a general service body that may not at times be overloaded.

It is certain enough, however, that the chassis builder has surrounded himself with all the safeguards that are consistent and it is further required by the majority of manufacturers that there shall be no changes in the chassis. This means that while a chassis frame may be shortened, for instance, there can be no change in the mechanical construction, as to the relation of the axles, the transmission, etc. Should there be changes then the guarantee is violated and the owner destroys whatever protection he may have had had he preserved the chassis as constructed.

As the owner must conform to the requirements of the manufacturer and the general design of the vehicle he has but one other reccurse and that is the type of body that he can install. While there may be needs that are urgent it is a fact that the body builder will know all the pitfalls and will be able to make a construction that will conform to all engineering requirements and give the necessary facilities.

Sizes of Standard Body Types.



In the building of motor vehicle bodies, both open and enclosed, there are certain sizes that are regarded as regular, these, perhaps, being accepted because of animal vehicle proportions. These dimensions relate to floor area or space and are, of course, subject to variation:

Weight of load, lbs.	Size in Inches	Area, Sq. Ft.
1,000	96x54	36
2,000	108x56	42
4,000	126x60	52.50
6,000	144x72	72
8,000	156x72	78
10,000	172x76	90.75

It will be seen that there is necessarily a considerable increase in depth as compared with floor area to give the varying capacities. For illustration, there is an increase of 16.66 per cent. of floor in the 2000-pound body as compared with the 1000, and 100 per cent. increase of floor in the 6000-pound body as compared with the smallest. Yet there is a considerable excess capacity of the 1000-pound body which, with a depth of 12 inches, would have space for not quite a ton of bituminous coal, or practically 100 per cent. overload. And coal is by no means the heaviest form of load that may be hauled. It will be noted as well that the 10,000-pound body has a floor area of about 120 per cent. more than the 2000-pound body. This indicates that the capacity is obtained by increasing the height or depth of the body, and consequently the height of the load and its centre of gravity above the surface of the roadway.

How Gravity Centre of Loads Are Changed.

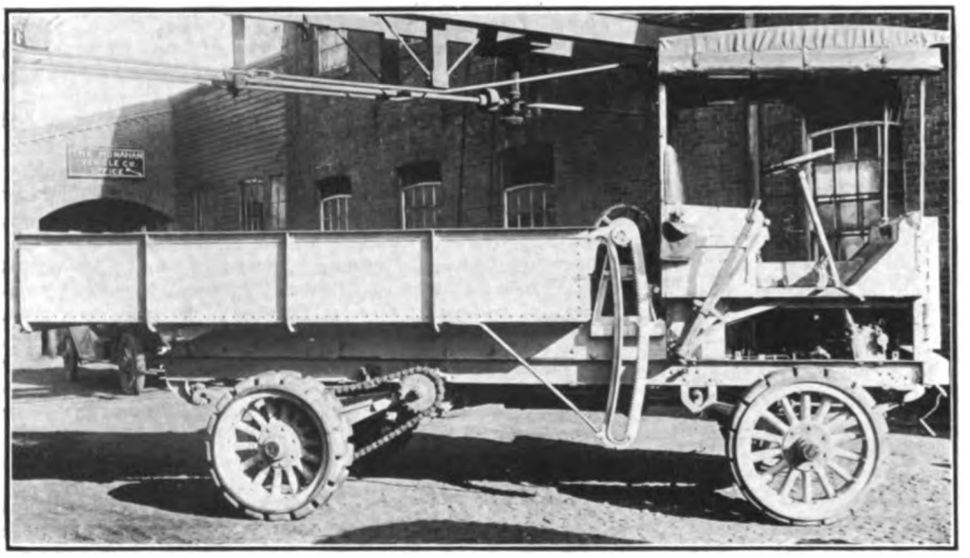
Taking a truck of five tons capacity as an example it will be understood that were the load of metal equally distributed on the deck or floor, centre of gravity would be low and the body space could be comparatively small. Were the load of stone the space would need be increased proportionately. As the load were varied and became more bulky it would be found that the body would necessarily be larger and the centre of gravity raised. Taking cases of cloth or the like a load might be piled eight or 10 feet above the floor and instead of being pyramid form might be stacked so that on a comparatively slight angle there would be a heavy side stress that would be greater and more severe than would the effect of a freight of decidedly greater weight with centre of gravity carried low. A full load of metal might be equally distributed as to weight in precisely the proportions intended by the designer, and yet the same weight of lumber might have stress entirely different. This being so it will be realized that while one or a few loads would not have material results, constant use under such conditions would eventually have destructive influences. The truck instanced, it will be recalled, was designed to carry five tons and for use with the load carried within estimated limitations. Obviously the floor area ought to be increased as the loads to be carried become bulkier to minimize the height of the centre of gravity of the load, but it is apparent with the increase of body floor there is no variance of the chassis dimensions.

Reliance Three-Ton Truck Chassis with Patent Steel Body Hoisted in Full Dumping Position, Showing Bolster on Which the Installation Is Carried.

It is a fact that wheelbase will increase materially with power wagon capacity, but the tread will not widen proportionately. The evident intention is to carry the load by increasing its proportions in length. The best illustration of this is that chassis frame width will vary from 36 to 45 inches, this being the extreme from the lightest form of delivery to the heaviest truck, while the wheelbase will range from 80 to 164 inches. The tread will increase from 56 to 72 inches with the wide forms of dual tires. With the conventional forms of bodies the width will vary from 46 inches for the enclosed delivery to 78 inches for the open truck equipment, but it is evident that the load of the smallest may be 500 pounds and of the largest perhaps 15,000 pounds, this being an increase of 69.5 per cent. in width and 2000 per cent. in capacity.

The body may be a plain platform with stakes and chain for the haulage of packages, cases, barrels, etc., or it may be with a body 12 feet in length, 66 inches wide forward and 78 inches wide at the rear, 30 inches deep and with flare boards that will increase the height to 40 inches, giving a carrying capacity of eight tons when the load is of coal and heaped. When bodies are built for carrying furniture they may be 174 inches in length and 72 inches in width, with depth of 15 inches. When the bodies are longer than this they are not regarded as regular or standard, but are special.

It may be said that requirements as met with in bodies are sometimes very widely varied and that larger bodies have been installed on 4000-pound wagons than on 10,000-pound chassis, this because of the load being light and bulky.



Though the argument may not be acceptable to those who desire to economize (from their own viewpoint) it is undoubtedly a fact that in choice of a body it is far better to consider the uses and select that which will afford the advantages and avoid the disadvantages. It is not judicious to assume that what can be packed on a body should be a reasonable load. Body space is not a measure by which to determine capacity and skyscraping loads are to to be

Digitized by Google

discouraged without reference to the class of vehicle.

Problems for the Designer to Solve.

These problems are for the designer and he must be guided by the chassis dimensions and the uses to which it will be devoted. This being so then it is essential that the chassis be examined, studied and analyzed, the proportions of the load to be carried on each wheel and each axle learned, the dimensions of the chassis frame noted, the requirements of the owner ascertained and the weight and the bulk of the proposed capacity load determined. With this data the size of the body necessary is arrived at and its position with reference to the chassis is established. Thus far no chassis have been built suited to carrying loads that are extremely long, such as lumber, metal rod, poles, and other commodities, for which special horse equipment is necessary. This means that to place a load of lumber 20 to 24 feet in length on a chassis with a body 12 feet in length, with overhang of four feet back of the rear axle, would carry practically all the weight on the rear construction, an exceedingly dangerous condition. Thus lumber 16 feet or less is the longest that should be carried in such a body. Neither is it practical to have the load extend greatly beyond the side members of the chassis, 16.5 inches being the greatest allowance for such extension by the most careful designers, and then only with bodies that would not have a load more than 36 inches above the truck floor. These are examples of the limitations to be found with chassis of regular models. It is probable that instances of this character may be cited with reference to practically every type of machine.

Three-Ton Alco Truck Equipped with Patent Steel Dumping Body with Monahan Patent Hoist, Designed for Coal, Contracting Material and Lumber.

The body designer takes nothing for granted. He is exceedingly careful to have accurate note and record. He must be as precise as an engineer or an architect, and he must have ability to produce whatever may be desired in ornamentation and to combine dignity and utility at least pleasingly.

Body construction for motor vehicles has as a basis skill in drafting, knowledge of materials, and precise note of the designer's requirements as to the chassis. It is thoroughly practicable for the experienced man to take a blue print of a chassis and to produce a body that will not only be exact as to installation, but will be in every way adapted to load limitations. But it is imperative that every detail of the chassis be known, even to the location of a rivet or bolt head. Once a body has been built for a specific chassis the work may be repeated with this model as often as desired, but the slightest change must be of record. One of the most confusing conditions is the change in chassis detail from time to time by the manufacturers, which necessitates constant revision of record.

Assuming that a chassis has been selected for a work and the purchaser has consulted the body builder, it is desirable, but not necessary, that the chassis be delivered to the maker. If the chassis is not received, a blue print must be sent to the builder, this giving a plan view and a side elevation. With the chassis the special blacksmith work may be fitted, but with the blue print this work may be constructed to specification.

Sketches and Working Drawings.

First the side elevation of the body is drawn to scale and then a half, cross or end section is laid down, although often a full section is prepared. Sometimes the drawings are of the side, with the half front and the half rear elevations, together with a half bottom view. The chassis is shown in dotted and the plan in solid lines. Occasionally the entire vehicle is shown in the plan. In the plan every piece of material is indicated and to proportion, and note is made of the number and the dimensions of each member. If the vehicle is covered frequently a half top or whole top, or a whole or half bottom view is given. The plan will show the location of each screw, rivet, bolt, brace, band, mortise, tenon, strip, post, panel, pillar, sill, bolster, stringer, molding, board or other component. It will show the exact size of each according to scale, and the relation of the one to the other so far as these should appear in the side, end, roof or bottom elevation. In the making of the drawing, which is the complete assembly, there must be exact knowledge of the dimensions and proportions of each part. When these facts are noted it is possible for the designer to take them and make up the total from which the drawing is prepared. In other words the drawing is not possible until after every necessary fact has been established.

Alco Three-Ton Truck Chassis Fitted with Three-Compartment Tank, Designed for the Delivery of Gasoline, Lubricating Oil and Kerosene.

The first work is a sketch and from this the estimates

Digitized by Google

are made and then comes the preparation of the specifications. In body building of recent years metal has been utilized to some extent for work that must endure, and this

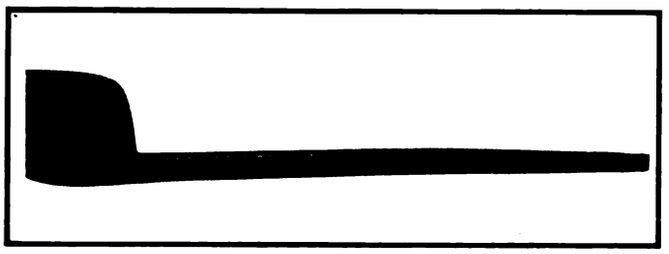


Fig. 1—Roman Front Platform Truck Body.

practise is extending, especially where the loads to be carried are heavy and the handling of the packages will quickly wear the wood. Metal sheathing has given way to heavier metallic construction because every element of strength may be had through the use of angles and tees and there is no possibility of deterioration from expansion and contraction of the wood through exposure to the elements in the course of the daily work. Not only this, the cost of wood has become almost as great as ordinary metals and it is procured with the greatest difficulty. This comment is interpolated to emphasize that knowledge of the value of metal in body construction is as necessary as of woods.

Preparation of Specifications.

In any sketch or draft that is made the body is usually drawn in connection with the chassis to illustrate appearance. This also makes it certain that the proportions are correct. To illustrate, the specifications for a working draft of a motor ambulance and casket wagon require the following parts:

Parts	Timber	Thickness, ins.	Width, ins.	Length ft.	Length ins
Bottom Frame of Body—					
2 Side sills	Oak	1.87	5.5	8	3
2 End cross bars, front and rear	Oak	1.87	4.25	3	5
4 Inside cross bars	Oak	1.25	4	3	5
4 Bottom boards	Oak	.63	9	7	7
Pillars and Posts—					
2 Coupe pillars	Ash	5.5	.	5	6
4 Side door pillars	Ash	1.75	.	5	4
2 Hinge door pillars	Ash	1.75	.	5	4
10 Inside posts	Ash	.87	.87	5	6
2 Rear end corner posts, curved	Ash	1.67	5.67	5	6
4 Rear door pillars	Ash	1.75	.	5	4
Rails, Cross Bars and Curves—					
2 Top rails	Ash	1.37	3.5	11	3
1 Front cross top rail	Ash	1.37	2.5	3	11
1 Rear cross top rail	Ash	1.87	5	4	4
4 Side rails	Ash	1.62	.75	5	11
4 Door rails	Ash	.87	2.25	2	.
4 Fence door rails	Ash	1.13	4	2	.
4 Bottom door rails	Ash	1.87	3	2	.

1 Coupe pillar cross top rail	Ash	1.75	5	4	4
1 Coupe pillar fence cross rail	Ash	1.13	4	4	2
1 Front centre pillar	Ash	1.75	.	5	2
1 Windshield curve	Ash	1.13	2.5	4	2
12 Other top curves	Ash	.87	.87	4	5
Panels—					
2 Bottom side panels	Poplar	.37	22	6	.
2 Belt rail panels	Poplar	.37	6	6	.
4 Upper panels	Poplar	.37	18	6	.
4 Belt rail door panels	Poplar	.32	6	2	.
4 Lower door panels	Poplar	.32	22	2	.
4 Top panels	Poplar	.32	14	12	.
Glass frame stuff	Ash	.565	1.87	50	.
Body moldings	Poplar	.37	.87	70	.
Drip moldings	Ash	.75	.75	35	.

Many Parts in a Standard Body.

It will be noted from count of the components that 90 are specified besides the stock for the glass frames and the body and drip moldings, and this is simply the woodwork. The body is composed of the frame and the panels (with the top when this is completely enclosed), the front, the rear gate or doors, the windows, ventilators, and so on, and each part must be created by the designer just as is any other work to exact measurement. Not only this, the dimensions of each tenon, each mortise, each lap, each splice, each socket, each radius is specified and each design for decoration is drawn. If metal is used the formation of the joints and the reinforcements must be drafted and provision made for these in the wood that is to be shaped and fitted about them, should this be necessary.

In this connection it may be noted that sheet metal has been used for many years for panels, particularly for service vehicles, and it has only been since the advent of the motor conveyance that aluminum has been utilized for panelling, it being susceptible of high finish and free from shrinkage or expansion from varying degrees of moisture. Sheet steel and sheet iron have been utilized wherever the wear has been excessive and there is today a disposition to use these materials to a greater extent than ever before.

With the preparation of the specifications it is necessary to designate every bolt, rivet, screw, or other fastening, and the number and proportion of each. In addition there is also description of all hardware of standard manufacture or of special type, and besides this each band, brace, bracket, rod, truss, clamp, clip, or other metal part that must be forged by the blacksmith is set forth in detail. Where it is necessary to build a bolster or under frame to install on the chassis to carry the body the components are similarly specified.

All Details Checked and Described.

The details when classified and systematically enumerated are checked through and then the main plan is drawn. Then the body is described and with this description is a series of working instructions relative to each particular assembly or group. These relate to the woodwork only.

Then in turn is a specification for the trimming department which relates to the upholstery, if this be made up in connection with the body work, and similarly a specification relative to the painting, with a sketch or sketches and whatever special design may be desired for the decoration of the body. Where carving or stamped metal is used the facts are similarly set forth.

The working drawings are made and frequently blue prints prepared and with these the specifications are sent to the foreman of the woodworking department. He usually selects the stock from the rough lumber and this is taken and shaped to the form desired. Selecting the stock is work for an expert, and when it has been picked out with reference to securing parts of the required quality with the least waste it is left with the wood workers. Meantime the specifications for the blacksmith shop have been sent to that department and finally when all parts have been made ready the workmen assemble the body, each part fitting perfectly.

The trimming is then begun and the work is made up in readiness for installation when the painting has sufficiently advanced, these two works being carried on together until the finishing is completed. Naturally there is an extreme range in these details according to the service for which the vehicle is intended. While it is possible to estimate with accuracy the stock that is required for the wood and metal work, as well as the trimming, the finishing is more or less variable and may be inexpensive or costly.

Small Body on Heavy Chassis.

Reference has been made to the necessity of the design-

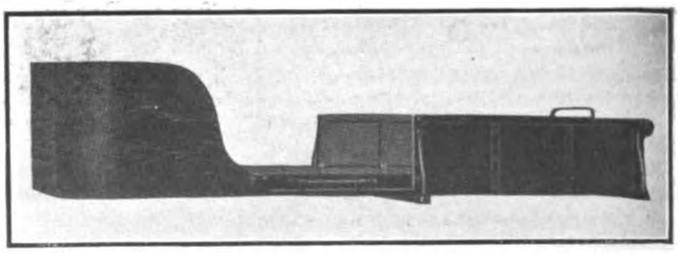

Fig. 2—Roman Front Truck Body with Side Panels and End Gate.

er considering the construction of the chassis on which the body is to be installed and that the character of the body ought to be with regard to the service, and to bear

Digitized by Google

out this statement it may be noted that in one instance where a truck was to be used by a steel company for the transportation of metal the builder installed a platform of the size that would have ordinarily been used on a 6000-pound chassis on a chassis rated at 13,000 pounds. The reason for this was that with the larger construction the truck might have been overloaded, and in any event with that type of deck the load might have been carelessly put on. With the narrower and smaller platform there was less probability of such abuse. There was little reason to fear the unequal distribution of the load with relation to the length of the smaller body, although this might have been a frequent happening with the regular size. Besides, there is a tendency of the load to work backward in a wagon when it is not properly packed.

There is another factor in load distribution that is exceedingly potent—the wear of the tires. This is a matter of decided importance with the careful body designer. While he cannot materially change the weight distribution upon the shoes he can so create the body that with proper loading the load will bear on the tires approximately as intended by the designer of the chassis, which will afford the largest margin of safety for the components of the machine, a condition that decidedly influences upkeep and maintenance. Bodies that are intended for one service may be built to carry a certain load and always under definite conditions when it is maximum. For instance, most of the bodies for brewery wagons and trucks are intended to carry 21 barrels in three rows of seven, but when these have been partly unloaded it is desirable to shift about those remaining so that great weight is not carried on one side.

How a Designer Estimated Capacity.

As an illustration of the possibilities in this direction a manufacturer who was about to purchase a truck sent for a body builder and asked his advice as to the chassis he should buy, saying that he wanted the truck to do certain work between his works and a railroad terminal. He shipped his goods in varying cases and received shipments in others of differing sizes. The designer went to the works, measured all cases that might be similar to those making up loads, and on the basis of these and the chassis capacity he outlined a body in which the cases could be packed which approximated the designs of several chassis. With this information the manufacturer made his choice and the body was constructed at the designer's works. It is needless to say that it has been a very satisfactory installation.

It might be possible to make numerous illustrations of a similar character in which the value of the special body is worth much more than might be believed. This is especially true of the springs of the truck which are usually much abused when the load is excessive. The springs will eventually weaken under a normal load by continued use, and where there is overloading there is always hastening of the day when the springs must be replaced. Not only this, there is the possibility of breakage because all the force of impact with any road obstruction must be sustained by the springs besides carrying the load. With the breakage of springs a truck must of necessity be withdrawn from service and there is the additional cost of the replacement, two unnecessary causes of loss.

Excess Stresses from Overloading.

Another danger from overloading through the poor design is when the load is so placed that a considerable excess of weight is carried on one side. This will result in a much larger proportion of the load stress being sustained by a single rear wheel, and when not on a level and when turning corners, with the tractive effort and the turning strain, the wheel is subjected to forces that cannot be long withstood. With this condition to be met with in constant service there is the best of reason why the capacity of the truck should not be exceeded.

In the development of the truck body the statement has been made that it is possible that the body builder has created designs that may be, with reasonable modification, adapted to many uses, and having these designs it is possible for him to produce individual orders at prices that are in every way reasonable. That a single design may be made in differing sizes for varying loads, and from different materials, has been stated, and in connection with this it is well to point to some examples of possibilities in this direction.

Platform Truck Body and Modifications.

Probably the simplest form of truck body is that known as the platform, which requires the installation of a deck on a chassis on which many kinds of loads may be carried. It is possible by the use of stakes or side boards to convert this body to other uses, and being open it may be utilized for numerous purposes. The basis of practically all truck capacities is floor area, a tabulation of standard sizes being previously given in this article. Reverting to this, and regarding as a truck a vehicle with carrying capacity of 6000 pounds, it will be seen that there is a variance of but four inches in deck width and 28 inches in length. This gives 18.75 square feet additional carrying space, or about 26.04 per cent. more with the larger vehicle, while the capacity increase is 60 per cent. Taking a load of the same commodity it would be necessary to pile the load higher on the larger body, and no matter how this is done the centre of gravity is necessarily higher and there must be a greater strength of construction than would apparently be justified by mere increase of load.

Taking the platform body for transporting heavy material this affords every need, but stakes are usually provided for the purpose of securing the load. These may be of any convenient length. A typical type of this design is illustrated at Fig. 1, this being known as a Roman front platform from the curved front, which is assumed to resemble the Roman chariot. This platform will not have quite the area of the square, but the reduction is slight.

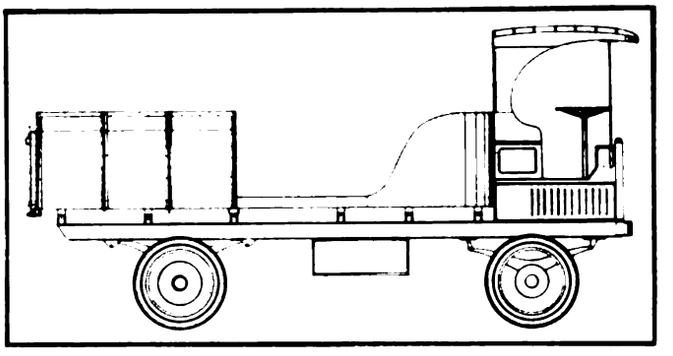

Fig. 3—Roman Front Steel Truck Body with Flare Boards on Sides and End Gate.

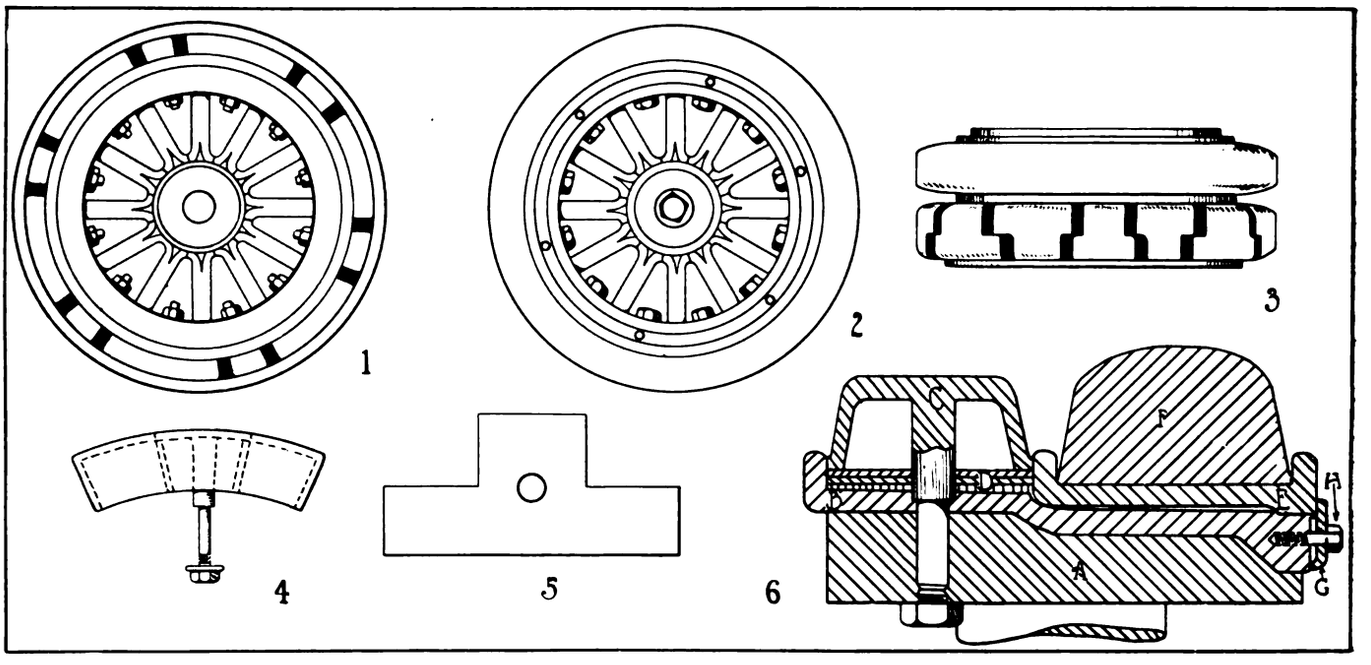
The front is of heavy sheet steel and serves to retain the load when packed. Stake sockets are bolted to the sills and with these a rope or chain can be made to form a light but effectual rail. The value of such a body is that it may be unloaded from either side or the rear and packages wider than the platform may be carried if the load should be bulky. This body is regularly built in 4000, 6000, 8000 and 10,000-pound sizes.

Taking this same design of platform body it is converted into a brewery wagon or truck by the installation of the sides as illustrated at Fig. 2, this being known as a Roman front body with side panels and end gate. This form is primarily designed to carry barrels at the forward section and kegs at the rear piled between the side panels. In this manner a full load may be well balanced by the pyramid form of the kegs, these being placed on the sides. The dash is extended back slightly and serves to retain the barrels, with abundant space for handling them, while rolls on the sides of the sills convenience loading and unloading. The side panels are secured to frames and well braced by extensions of cross members at the ends of the frames and by iron braces from the tops of the panels to the extensions. This body has the capacities stated for Fig. 1.

Still another illustration of the use of this type body is shown at Fig. 3, which is designated as a Roman front steel with side panels and end gate, with flare boards on the side panels. This body is intended for the same general use as is that at Fig. 2, but it is somewhat differently proportioned as to sides and front, these being higher and permitting a larger load. The platform frame of this body is of wood

Digitized by Google

and on this is carried the steel body, a construction that is especially enduring and which ought to be serviceable for a long period. The body is differently constructed than are the others and it is, of course, more expensive, but it has a similarity in design that is apparent. This body is built to the same capacities as are the others.



It is probable that no better examples of bodies might be pointed out for those who desire to give some attention to design and construction. Taking the plain platform, for instance, it is but slightly modified as compared with the deck having squared ends, and with the foundation of the deck it is possible to devise a very large number of bodies, each of which presents features differing generally, if not wholly, above the platform.

(To Be Continued.)

BALDWIN SECTIONAL STEEL TRUCK TIRE.

L. F. N. BALDWIN, Providence, R. I., who is noted as a racing driver, and is one of the best known motorists in America, has invented a sectional steel tire which he claims possesses qualities that particularly adapt it to heavy vehicle service and which, he maintains, can be adapted to any rim now in use. This tire is designed to be used in combination with solid shoes of the present types, Mr. Baldwin claiming for his invention that it will minimize the wear and greatly prolong the life of the rubber tire used with his device.

The tire is unique in that it may be adapted to conform to the reduction in size of the rubber shoe through wear and that the diameter of the wheel as a whole may be varied as desired. This is accomplished by using metal liners or shims between the block and the rim. By these the external diameter of the tire may be increased or lessened, a process that requires but little time.

The Baldwin Combination Steel Block and Rubber Tire for Service Wagons.

As may be known, rubber and rubber compositions cannot be compressed, but can be distorted. Under the pressure of loads and driving stress any solid tire will change its form and the tendency is for the material to be forced from the actual place of contact of the tire and the ground or paving on which it stands. As the tire wears the resiliency from the elasticity of the rubber compound is lessened because there is a reduction of material.

Because of the rear wheels carrying the greater part of the load as well as transmitting the power the tires wear more rapidly than the forward shoes, for which reason dual tires were adopted. Mr. Baldwin claims for his invention that the steel shoe carries the load and resists the wear, and the rubber shoe affords the traction necessary. He holds that on ordinary unpaved roads there is no need of carrying the load on rubber alone and that on paving traction is a condition more required than a cushioning effect or the reduction of noise. The steel tire is to be used with the surface slightly lower than the normal face of the rubber shoe so that under compression the rubber and steel surfaces will contact with the road surface. With the weight of the load largely carried by the steel tire he claims economy in that there is a reduction of the rubber surface a half, while the combination insures traction under all conditions of service.

The tire blocks may be made of any metal desired, but manganese steel is a probable material because it may be cast and it has unusually enduring qualities. As will be noted at Fig. 3 and Fig. 4 the blocks are formed so that when installed there is a space between the ends, which is to provide for the reduction of the external diameter of the tire. This space will vary from an inch to an inch and a half in width and it will afford traction on all unpaved roadways where the blocks contact with the ground. Reference to Fig. 6 shows a cross section of a block, which is cored to secure lightness. The blocks are secured to the rim and felloe by bolts cast integral with them. The blocks are so located that the bolts are about midway between each spoke. They are secured by nuts and lock washers or other device.

The method of installation is to fit a special rim to the wheel, the form of which is illustrated at Fig. 6, and this is shaped with a flange at the inside. Against this flange the shims are placed, and on these shims the block, the same bolt that retains the block retaining the shims. The channel section carrying the rubber tire is installed as is any solid wheel shoe, one flange of the channel holding the block rigid against the wheel rim flange. When a new installation is made the surface of the rubber tire is about an eighth inch above the steel blocks, or a quarter inch more in diameter. As the rubber is worn a shim may be removed from beneath each block, and the shims may be of any thickness that practise will dictate, so that the diameter of the steel tire is uniformly reduced until a point is reached where the rubber tire is no longer serviceable.

With the rims now the vogue the blocks may be installed by drilling the rim and felloe for the retaining bolts and the block may be retained against the rim flange of the

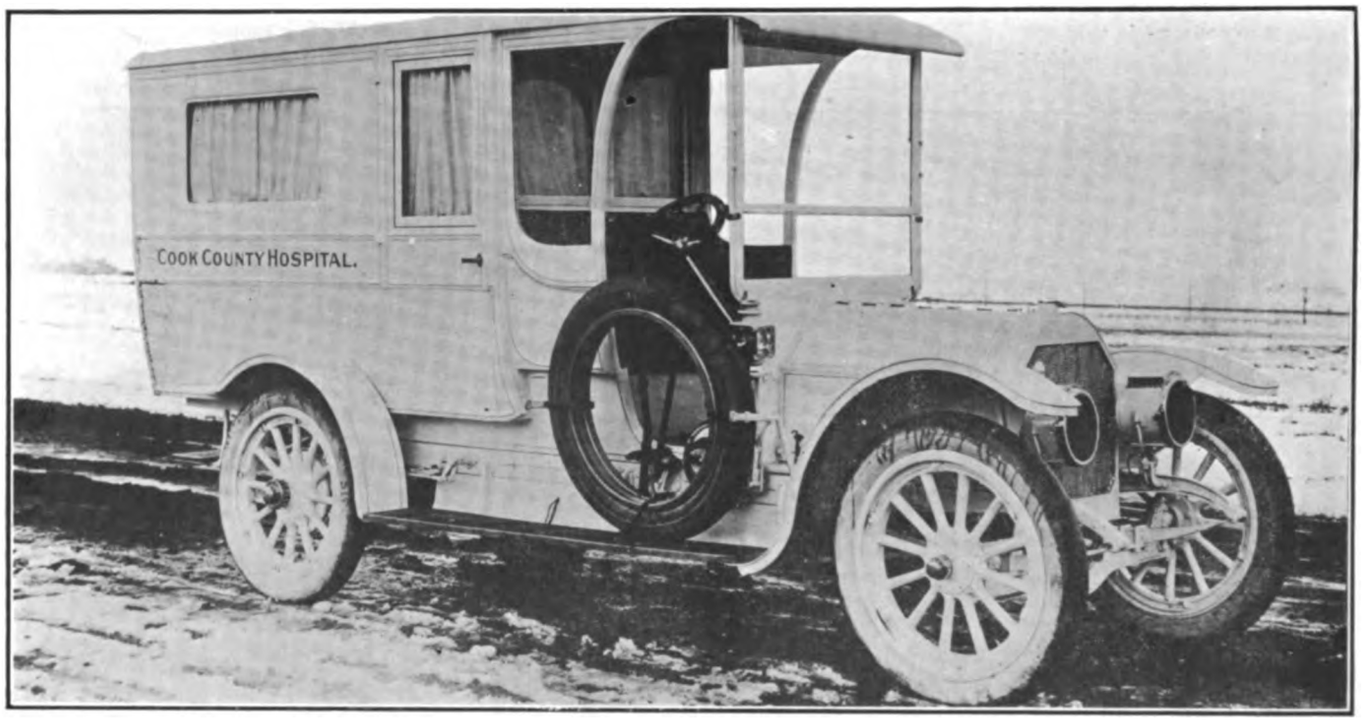
Digitized by Google

rim by the channel of the rubber shoe. The wheel felloe and rim may be made any thickness and width that is desirable and the width of the steel tire whatever proportion is necessary to yield the best service. The rubber shoe is mounted on the outside of the rim to facilitate ease in installation or removal. It is not believed there will be occasion to remove the blocks unless for the reduction of diameter by the thickness of a shim as necessitated by the wear of the rubber shoe. The construction has the merit of cheapness and endurance and it is held by the inventor that the tires, when used wherever dual shoes are installed will yield equal results so far as riding qualities are concerned, will give far greater mileage for the rubber tires, thus lessening the expense from one point of view, while the metal castings, after the first equipment, will be useful for a considerable period—perhaps several years.

The descriptions of the detail drawing are: Fig. 1, side elevation of wheel, showing side of sectional blocks retained by bolts through the felloe. Fig. 2, reverse elevation of wheel, showing rubber shoe retained by flange and bolts or cap screws. Fig. 3, plan or top view of tire assembly, showing blocks and spaces. Fig. 4, side view of steel tire block, the dotted lines indicating the core. Fig. 5, plan view of steel shims. Fig. 6, cross section of tire assembly with these components: A, wooden wheel felloe; B, steel tire or wheel rim; C, cored steel block and retaining bolt; D, shims between steel block and wheel rim; E, demountable channel carrying rubber shoe; F, rubber tire; G, retaining flange or ring; H, retaining bolt or screw.

HOLD THREE-DAY CONVENTION.

The first annual convention of the agents of the Speedwell Motor Car Company, Dayton, O., was held recently in that city and the event occupied three days during which time the visitors were royally entertained by the company. During the daily sessions the visitors were addressed by the heads of the different departments and the subjects included advertising, accounting, service, engineering, care and operation. Harry Croninger, who is in charge of the commercial department of the company, and who has a wide experience in truck work, addressed the convention upon the co-operation between the factory, agent and owner, imparting much valuable information. Matters pertinent to the truck industry were discussed. Those present included agents from all sections of the country.



REPORTS GOOD TRADE PROSPECTS.

According to George L. Sullivan, Alco sales representative of the American Locomotive Company, New York City, who returned recently from a trip extending over a period of two months, the prospects are excellent for large sales in the spring. He states that all over the country visited by him heads of business concerns are investigating the possibilities of the commercial vehicle and many have decided to replace the horse drawn equipment with the motor car.

In one city of 92,000 persons, Mr. Sullivan reported that eight cars would be sold, five of these to be bought by one house, a big department store with branches covering considerable territory. These machines will be ordered before February. A meat packing concern in the same city is to place a car in operation to haul its product from a town 36 miles away, and expects to double its present facilities.

In another western city a moving and transfer concern which makes long distance hauls to nearby towns, will add automobiles to take care of this end of the business. Another concern is figuring on 10 cars to be fitted with special bodies to compete with street car lines.

A plan whereby five business houses, all of different types, could be utilized on a community basis, has been worked out by a truck dealer in one city, and it is proposed to purchase six machines and operate these jointly, thus effecting a considerable saving in the initial cost and maintenance.

Ambulance Body Designed and Fitted to 50 Horsepower Chassis By the Kissel Motor Car Company, Hartford, Wis., for Cook County Hospital.

REPEAT ON LAUTH-JUERGENS.

One of the best evidences that a motor vehicle is giving good service is held to be the fact that concerns give the maker repeat orders. This being true, it would seem that the Katz Mattress Company, Chicago, has been decidedly satisfied with its first Lauth-Juergens truck, made by the Lauth-Juergens Motor Car Company, Fremont, O. The latter concern recently received an order for two two-ton vehicles, it being the third repeat order sent in by the mattress company.

Digitized by Google

KNOX TRUCKS REPLACE HORSES.

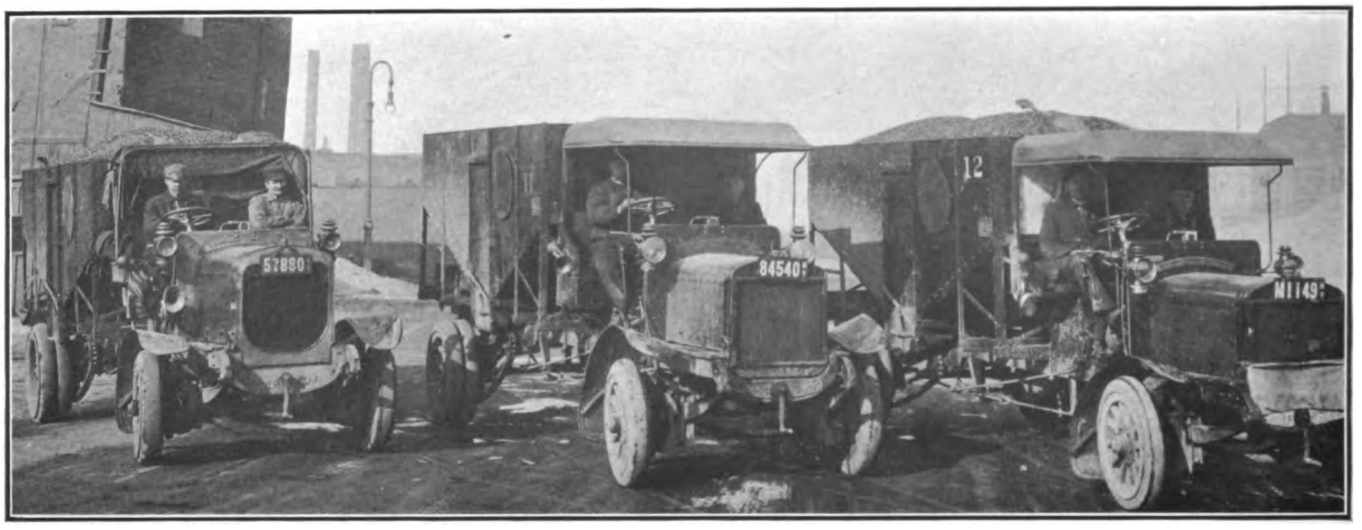
Worcester business men were afforded an opportunity to note the progress of the commercial vehicle recently when the Worcester Brewing Company, W. H. Blodgett Fruit & Produce Company, the W. N. Gleason Company and the American Mail Order Company, discarded the old time railroad delivery of goods which necessitated packing and hauling to the freight depots. In place of horse drawn equipment motor trucks have been installed and, whereas it formerly required two days to deliver goods to Leominster and Clinton, it now takes but two hours. A Knox three-ton truck, made by the Knox Automobile Company, Springfield, Mass., in service with one of these companies left Worcester one day at 11 in the morning and arrived at Clinton at 1:45 in the afternoon, unloaded at several places, and was back in Worcester ready for other deliveries a few hours later. Knox cars are utilized by all the firms mentioned.

ADDS FIVE COMMERS TO FLEET.

Last winter the firm of H. L. Herbert & Co., New York City, a large coal dealer. experimented with a 6.5-ton Commer truck, which was placed in service by Wyckoff, Church & Partridge, Inc. An earlier test of motor propelled vehicles by the concern is said to have been unsatisfactory, but the improvement in the automobile and success of other coal companies led it to try the Commer truck, and for 13 days during the cold weather this car was subjected to strenuous work.

During the time the cost of operation and work performed was noted and it was found that 572 tons were hauled at a cost of less than six cents a ton mile. This led the company to order a similar machine, which was placed in service in April. A trifle over four months later a second automobile was purchased, and with the contract was a letter which stated that the first vehicle had lived up fully to the record made in the demonstration.

In November a third car was secured and the company promulgated a plan to replace its horse drawn equipment with the motor propelled vehicle, giving an order for five more, making a total of eight in service. In the accompanying illustration is shown three of the cars fitted with special coal dumping bodies, the photograph being taken at the yards of H. L. Herbert & Co.



METZGER TO BUILD ONE-TON TRUCK.

The Metzger Motor Car Company, Detroit, announces that although it has resold to the Hewitt Motor Company of New York City, a large share of the truck business formerly conducted by the concern, it will continue to manufacture in Detroit, the one-ton model, which will be known hereafter as the Everitt, instead of the Hewitt, as formerly.

In speaking of the matter W. E. Metzger said recently: "We have by no means discontinued the manufacture of commercial vehicles. Lack of facilities in the past has prevented our giving much attention to this branch of the business, and rather than divide our energy, we decided to dispose of a portion to E. R. Hewitt's new company, retaining the right to built the one-ton size. We shall continue to make this car in Detroit without interfering with our pleasure automobile business, and its small size will enable us to manufacture in quantity. Operations have already begun and the new models will be marketed early in the spring. Their distribution will be effected by over 400 dealers handling the Everitt line."

SHIPPING GAS TANKS ABROAD.

According to the Prest-O-Lite Company, Indianapolis, Ind., when automobiles are exported it is necessary to certify on the steamship bill of lading that fuel, water and gas tanks are empty. Unless this is done the companies will refuse to accept the shipment even if the car be crated and boxed. The Indianapolis company suggests that to prevent the uncrating of the machines and emptying the tanks, an empty member be utilized and that a conspicuous label be employed to denote this condition. A list of the countries where tanks may be exchanged for full ones is published by the company and may be obtained upon application.

Recent Addition to the Fleet of Commer Trucks in Service with H. L. Herbert & Co., New York City—This Concern Bought Its First Truck in April and Now Maintains Eight Machines.

CONTEMPLATE MOTOR 'BUS LINE.

Business men in Fort Dodge, Ia., are contemplating the organization of a company to finance and operate a motor 'bus line in that place. The scheme calls for at least four machines and these will be operated on regular runs, reaching all parts of the city.

MAIS EXHIBIT AT NEW YORK CITY.

During the automobile shows in New York City recently the Mais Motor Truck Company, Indianapolis, Ind., exhibited two models in the National Boat salesroom, opposite Madison avenue entrance to Madison Square Garden. The display attracted considerable attention, being so located that patrons of the show could find it easily. President and General Manager Will H. Brown and C. H. Wallerich were in attendance and explained the features of the car with the internal gear drive.

ELECTRIC VEHICLE BREVITIES

Robert McAllister Lloyd, vice president and general manager of the General Vehicle Company, Long Island City, N. Y., in discussing the transportation problem recently, brought out some pertinent facts regarding the standardization of the electric vehicle, a step which he advocates and one which he states would be a great benefit both to the manufacturer and purchaser.

"It has been fully demonstrated by the results obtained during the past 10 years that self-propelled road vehicles may be used economically and advantageously to displace the horse drawn equipment, also to compete with railroads in certain classes of transportation," says Mr. Lloyd. "But owing to the many systems utilized in the application of power and great variety of designs, the buyer and user of the electric vehicle is likely to suffer much inconvenience from the lack of uniformity of design unless steps are taken to standardize the working parts and some of the auxiliary apparatus.

"There is strong evidence that both the electric and gasoline machine will be used in large numbers and automobile engineers and makers are beginning to study the possibility of making interchangeable some of the features common to both types of cars. The principal item to suffer from use on all vehicles is the tire, and a consideration of this problem has resulted in the recent adoption by most manufacturers of standard wheel and tire dimensions, which make it possible to interchange various makes of tires on any standard rim. There are many other items common to both the gasoline and electric which are being standardized but these are mostly minor details.

"A standard voltage should be agreed on and battery compartments of standard dimensions should be adopted. This would enable the operator of a vehicle to borrow or rent a battery in an emergency and would permit the owner to take advantage of improvements in batteries coming on the market from time to time. At present there is no standard as to the number of cells constituting a battery and therefore the charging equipment needed for one wagon may be different from that required by another. The voltage of electricity throughout the country is so nearly uniform that it would not be difficult to agree on a standard battery voltage and so make possible the standardization of charging switchboards with their instruments, rheostats, etc., as well as the instruments utilized on the vehicles.

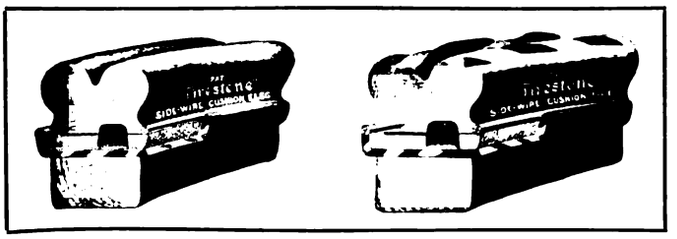
"The majority of electric commercial vehicles use a 44-cell battery having on discharge about 88 volts. The motors on these cars are rated at 85 volts and 90-volt lamps are employed, and the charging switchboard is designed accordingly. Some machines are equipped with 24-cell batteries and other combinations. Confusion and sometimes damage result from attempts to charge these lower voltage batteries in garages where wagons with higher voltages are maintained, and there are many serious disadvantages in grouping vehicles of various voltages in the same garage. Low voltage lamps are burned out when they happen to get into high voltage wagons and low voltage members are spoiled in charging from high voltage switchboards.

"The number of cells required for a given voltage of Edison battery differs from that needed for the common lead type, and the voltage of the motor and lamps used would be different. It is possible, however, to fix upon a standard number of Edison and lead type cells which could be charged from the same switchboard. If all electric vehicles were equipped with either 44 cells of lead battery or 60 cells of Edison, it would enable the manufacturer of motors, etc., to produce these articles to greater advantage and give better satisfaction to the users.

"Thus far the makers have not been very successful in getting together on the question of standard battery voltage, but this should be accomplished. It would be unfortunate if action were delayed, as in time the amount of obsolete material thrown on the scrap heap will be far greater than it is today.

"If standard voltage should be adopted for all electric vehicles not only would batteries be interchangeable to a great extent, but also motors and possibly controllers. The fact that an owner could exchange motors with his neighbor or re-equip an old car with an up-to-date power plant, or with one part of it at a time, would place the electric in a unique position as compared with other automobiles. It would be a short sighted policy for any manufacturer to take the stand that he preferred to construct his machine so that a motor, controller or battery made by another firm could not be applied to it.

"It is recognized that the electric vehicle is more fool proof and easier and more economical to operate within its radius of action than a gasoline car, and it would be folly not to take advantage of the opportunity to make its most important features interchangeable, as this would add greatly to its popularity and hasten the time when the horse shall be permanently retired to agricultural pursuits."



Anderson Electric in Service with Grocery Firm at Winnipeg, Manitoba, Having Given Excellent Satisfaction Under Severe Climatic Conditions.

A newcomer in the ranks of commercial electrics is the Argo Electric Vehicle Company, Saginaw, Mich., which concern makes two models of 1000 and 2000 pounds ca-

pacity, respectively. These vehicles utilize a shaft drive with a herringbone gear for the final reduction, which method is said to result in high efficiency, silence and com-

The New Firestone Cushion Tire for Electrics: At Left, Depicting the Smooth Tread Type; at Right, the Anti-Skid.

pactness. The smaller vehicle is known as Type 10, has a wheelbase of 86 inches with tread of 54 inches, and is fitted with solid tires, 34 by three inches. The battery equipment is 28 cells, 11 plates M. V., Exide being standard, but Ironclad or Edison are furnished as extra. The body provides a loading space 90 by 42 inches.

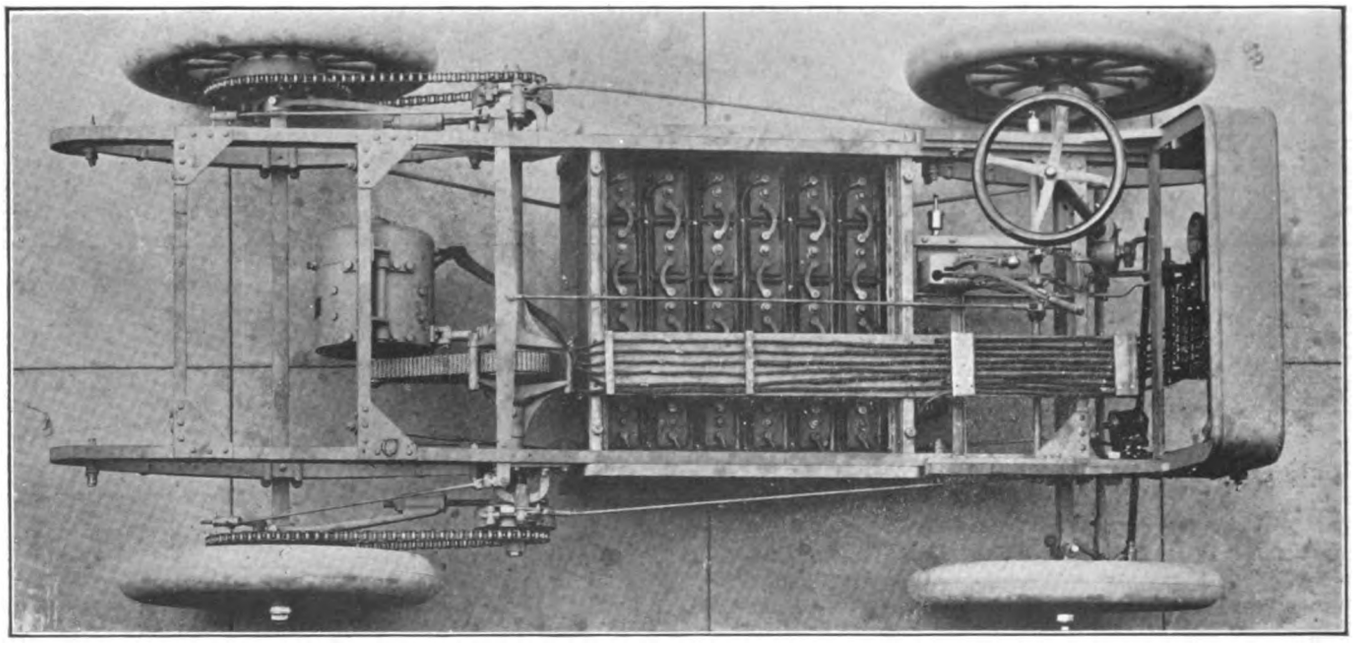
★

The Firestone electric tire, made by the Firestone Tire & Rubber Company, Akron, O., with which electric vehicle users are familiar, has been improved in many ways, particularly in its easy riding qualities. This has been brought about by fitting the tire with a double or dual tread and by the addition of internal cavities at frequent intervals in the base, directly under the tread whereby the full cushioning effect may be secured. The dual tread was introduced for motor truck tires by the company about five years ago and was generally adopted. It not only provides a cushioning effect but serves to prevent skidding. By placing the cavities wholly within the tire an exceedingly neat and attractive appearance is secured. To obviate creeping and to ensure a firm fastening on the wheel the side wire method of attachment is utilized, and this form is in general use on heavy commercial vehicles. The tire which is manufactured in smooth and anti-skid tread, as depicted herewith, is known as the Firestone side wire cushion electric, and although it has been on the market some time it has not been widely advertised until recently.

★

The practicability of the electric commercial vehicle is demonstrated by a 1000-pound capacity machine in service with the A. Macdonald Company, wholesale grocer, of Winnipeg, Manitoba. The vehicle, which is made by the Anderson Electric Car Company, Detroit, Mich., is fitted with a battery comprising 60 A-6 Edison cells, and during the six months it has been operated it has averaged from 40 to 50 miles a day, during part of which time the temperature has been as low as 20 degrees below zero. In the accompanying illustration is presented the car carrying one of its usual loads, and in writing of the automobile the owner states it has given excellent satisfaction.

★



The growing demand for power wagons for light delivery work has stimulated the development of electric vehicles to such an extent that they are fast replacing the horse drawn equipment. Many department stores have adopted the electric after experimenting with various types of mechanically propelled vehicles, and in several cities large fleets are maintained.

The Kentucky Wagon Manufacturing Company, Louisville, Ky., successor to the Electric Vehicle Company of that place, has brought out two new models of 600 and 1000 pounds capacity, respectively, and in the accompanying illustration is depicted a chassis of the former type. These are fitted with different body designs to meet the requirements of the purchaser. Without departure from thoroughly conservative practise, the maker has incorporated a number of refinements which make for long life, low cost of upkeep, high mileage, accessibility of parts and convenience to the operator.

The motor is a General Electric, 60 volts, and is suspended from the main frame just forward of the rear axle. Power is transmitted to the countershaft by a silent chain enclosed in a dust proof steel case. Final drive is by roller side chains, a system that makes for simplicity, efficiency and accessibility. The countershaft is of the enclosed type and is carried upon ball and roller bearings. The motor shaft is mounted on Hess-Bright annular ball bearings. Bower roller bearings of ample dimensions are utilized in the rear wheels.

The battery is mounted on a sub-frame immediately in front of the countershaft. The 600-pound capacity model is equipped with 30 cells of the lead plate type while the larger vehicle is fitted with 50 Edison A-4 cells. This equipment is stated to give a mileage of from 40 to 50 under normal service conditions. When a higher mileage is desired a larger battery equipment will be provided. It has been the experience of the company, however, that the standard battery is sufficient to meet all usual requirements.

The controller is of the continuous torque type, affording three speeds forward and two reverse. Its location is a departure from ordinary practise, as will be noted in the illustration herewith, being bolted to the dash and protected

Chassis of 600-Pound Capacity Electric Delivery Wagon Brought Out by the Kentucky Wagon Manufacturing Company Which Is Noticeable for the Number of Refinements and Accessibility of Mechanism.

Digitized by Google

by a short hood, and this part of the system with its wiring is easily accessible by the removal of the light dash panel which is held in place by four thumb nuts. This hood serves to protect the headlights, meter and switches, and the vehicle body is free from wiring. This is a desirable feature, inasmuch as the body may be removed after six bolts which hold it to the frame have been taken out.

The brakes are two in number and have liberal friction surfaces, the service member being of the contracting type operating on drums riveted to the countershaft sprockets and actuated by a pedal through a flexible equalizer. The emergency member is of the expanding type operating on the rear wheels by a latched lever through an evener which extends through the frame just above the countershaft. Both brakes are eight inches in diameter and of two-inch face.

The frame is of channel section pressed steel, with three well gusseted cross members of the same section. Truss rods running from the forward cross member beneath the sub-frame and up to one of the rear cross members, prevent the frame from sagging, and permit of a light frame section.

The front and rear axles are of the I beam section type and the forgings are weldless, from end to end. The steering knuckles are of the reversed Elliott type. The springs are long, semi-elliptic, both front and rear. The wheels are of selected hickory, artillery type and are fitted with solid tires, 34 by 2.5 inches, though pneumatics are furnished at an extra cost. The wheelbase is 86 inches and the tread standard, 56 inches. A Sangamore ampere-hour meter is utilized and this is mounted on the dash.

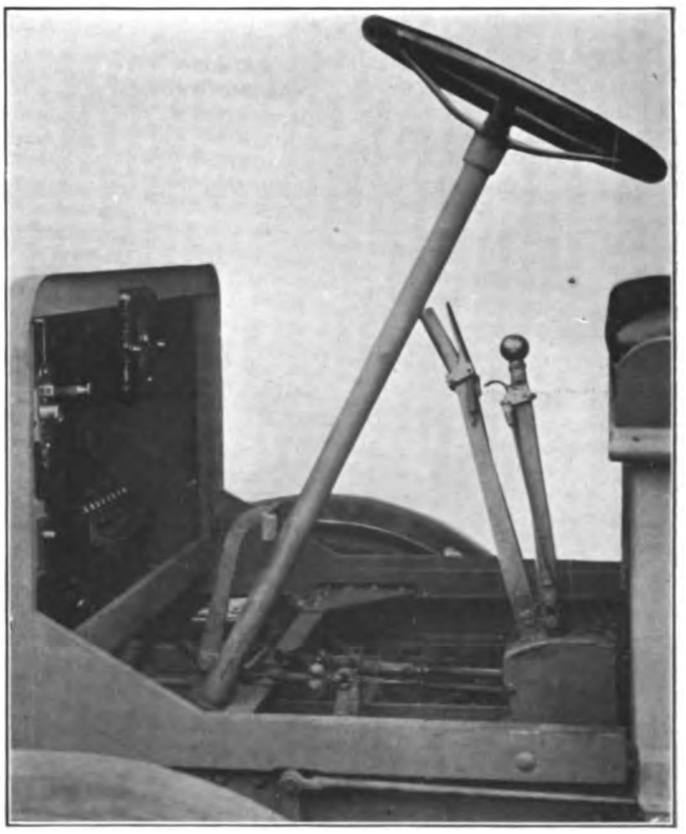
Steering is accomplished through a semi-reversible worm and gear mechanism, and this is fitted with hardened gears and ball thrust bearings. The steering column is raked at an angle of 25 degrees from the vertical and the usual wheel is provided.

Believing that the question of control had not received the deserved attention from designers, the company has considered this subject carefully and located the driver at the left, placing the control and emergency brake levers at the right in the centre of the car. The control lever is operated in a gate, being moved forward for the four forward speeds, and back for the two reverse. Before passing from neutral to reverse a latch must be raised and the side lever given a side movement, thus providing against accidental reversal.

The emergency brake lever is operated by being moved to the rear. When the machine is at rest it will be noted that both levers occupy such a position as to insure easy entrance and egress of the operator from either side of the car.

In addition to the control lever, an emergency lock switch is provided which opens the circuit when a plunger is pulled out. The latter locks in open position and may be returned by the use of a Yale key. This arrangement prevents use of the machine by others than the driver or authorized person.

Liberal provision is made for lubrication of all parts subject to the slightest wear. Brake and control set shafts are made hollow and provided with one large grease cup each by means of which lubricant is forced to all necessary points. The spring eyes are fitted with grease cups made integral with the hardened and ground shackle bolts. Oil and grease cups are provided on all steering connections and knuckle pins, and countershaft bearings are similarly equipped.



Two protected flush type electric headlights are mounted on the dash and the tail light is also operated by electricity. The standard type of body fitted to the 600-pound vehicles is panelled, and affords a clear loading space 60 inches long, 42 wide and 60 high. A similar body is provided with the larger car, this providing a space 73 inches long, 42 wide and 63 high. Other types of bodies are optional.

Electric vehicle manufacturers are anticipating with enthusiasm the 1912 Boston electric show, which will occupy the entire Mechanics' building in that city from Sept. 28 to Oct. 26, inclusive. The event will include displays of every known application of electric energy.

About 15,000 square feet of floor space has been set aside for the electric vehicle section, and nearly two-thirds has been engaged by manufacturers. All of the modern cars will be displayed, both pleasure and commercial, as well as the latest appliances utilized in connection with the machines and designed to bring about high efficiency.

Visitors and prospective buyers will have every opportunity to see the machines demonstrated as well as every facility for consulting statistics and learning from others how well the electric automobile does its work. In addition to the cars, an electric vehicle garage will be maintained in the building, and although a sample, it will be a model for practical adoption. The costs of various items usually included in garage charges will be based on efficiency in the operation of the garage, and an effort made to demonstrate how one is run where highest efficiency of service for customers with average profit for the management is secured.

Machines for demonstration purposes may be cared for at this garage, and it is expected that the various large users of electric vehicles for commercial purposes will keep cars there during the month. That the show will be a decided success as well as accomplishing much in interesting the public in the electric automobile, is conceded by those familiar with the subject, and this will be due in a large measure to the efforts of the Edison Electric Illuminating Company of Boston, which has been active for some time in promulgating information concerning the electric vehicle.

Depicting the Location of the Controller and Accessibility of Parts on Kentucky Wagon.

Day Baker, New England manager of the General Vehicle Company, Long Island City, N. Y., gave a stereopticon illustrated lecture before the New England Foundrymen's Association at Boston recently. He showed a large number of pictures presenting the progress of the electric vehicle from 1886 to the present. Of particular interest were the illustrations of baggage and factory trucks, six of which have been installed in the North station at Boston. The devices for factory work are operated at a moderate speed and are capable of carrying a very heavy load. A form of carrier utilized by large beef dealers also was explained and illustrated.

FIRE DEPARTMENT NOTES

The practicability of the motor propelled fire apparatus was demonstrated to the citizens of Pittsfield, Mass., recently when with a gale blowing, fire broke out in a dangerous locality. The automobile made a record run, averaging over 40 miles an hour and reached the scene of the blaze so quickly that the flames were extinguished before they could communicate with the large number of oil barrels stored in the building. Chief Shepard of the department stated that the machine more than paid for itself at this fire alone.

The municipal authorities of Lynn, Mass., which is considering the purchase of motor fire apparatus, were given a demonstration of a 50 horsepower vehicle made by the Mais Motor Truck Company, Indianapolis, Ind. The chassis is specially designed for this work, is fitted with the Mais internal gear drive and is guaranteed to travel at a speed of 30 miles an hour for fire department work.

The trials were on Cedar, Greenwood, Mansfield and Hudson street hills, John C. Welsh, the Lynn representative of the company conducting the tests. All of the hills were climbed easily and the city authorities were very much pleased with the demonstration. It is proposed to fit the bodies of the present horse equipment to a motor car chassis.

Combination Hose and Chemical Wagon Made by Martin Carriage Works, York, Penn.

The Martin Carriage Works, York, Penn., maker of commercial vehicles, is manufacturing automobile fire apparatus and in the accompanying illustration is depicted a combination hose and chemical wagon produced by that company. The vehicle carries a large chemical tank and hose and the usual equipment in the shape of ladders, axes and other fire fighting appliances. The body accommodates several men, being roomy and well designed for the purposes for which it is intended.

The vehicle is propelled by a four-cylinder, four-cycle, water-cooled motor, with a 4.5-inch bore and five-inch stroke, rated at 36 horsepower, and its location is under the seat. Ignition is furnished by a magneto with battery in reserve. A multiple disc clutch is employed and a selective sliding gear affords three speeds forward and reverse with direct drive on third. Final drive is by side chains and two sets of brakes are utilized, on jackshaft and rear wheels. The front springs are semi-elliptic and rear half-platform. Solid tires are employed and the wheelbase is from 132 to 140 inches.

Throughout the country there is a growing tendency to replace the horse drawn fire equipment with motor propelled apparatus, and this movement is not confined alone to the large cities as the small towns, also are adopting the automobile. Many cities have expended large sums for modern horse drawn apparatus such as engines, etc., and these only lack the proper means of transportation to give efficient service. To discard this means a considerable loss as well as outlay of money to install the more modern equipment.

To devise a mechanically propelled vehicle adaptable to the horse drawn type, Charles H. Martin experimented with many designs and after much labor produced the Martin three-wheel tractor, a form of automobile constructed to haul the horse type of vehicles. The invention was taken up by the Knox Automobile Company, Springfield, Mass., well known maker of automobile fire apparatus, and subjected to a series of severe tests all of which the tractor withstood successfully.

The device consists of a steel frame, carrying a motor and transmission machinery, which is placed in front of the fire engine or any other apparatus designed to be horse drawn. In the accompanying illustration the tractor is geared to the front wheels and axle of a steam fire engine, and it will be noted that it is supported in front by a single wheel, which is utilized for steering and which permits of a five-wheel combination to be turned in a narrow street.

This wheel is suspended upon liberal springs which reduce vibration to a minimum and the engine and working parts of the design are protected thereby from road shocks. Drive is by side chains to the traction wheels of the fire engine and suitable springs are fitted, these being said to be fuly as resilient as those of the pleasure car. It is claimed that the members which support the tractor on the axle act as a cushion and that a considerable advantage is gained in starting a heavy load from a standstill. A sliding gear transmission facilitates this operation.

The tractor was exhibited at the recent New York show by the Knox Automobile Company, and attracted considerable attention from those interested in fire protection as every city in the country has horse drawn apparatus of proven worth that does not lend itself to ordinary automobile construction. In testing out the device it was driven over curbs, through plowed fields and sand banks, and did work successfully that an ordinary commercial car would not be called upon to do.

Chief A. V. Bennett of Birmingham, Ala., which city is equipped with several pieces of motor propelled fire apparatus, has been presented with another check for good work performed by his motor car department at fires. During October the automobile apparatus responded to 105 alarms, ran 1930 blocks, laid 15,250 feet of hose and used 366 gallons of chemicals.

Westfield, N. J., has placed in service its new Webb motor fire engine made by the Webb Motor Fire Apparatus Company, St. Louis, Mo. It is guaranteed to deliver 700 gallons of water a minute, taking suction from a plug of 45 pounds pressure and discharging through two 50-foot siamesed into one line, playing into one two-inch tip, or 650 gallons, taking suction from an open body of water with not over a nine-foot lift and discharging through two

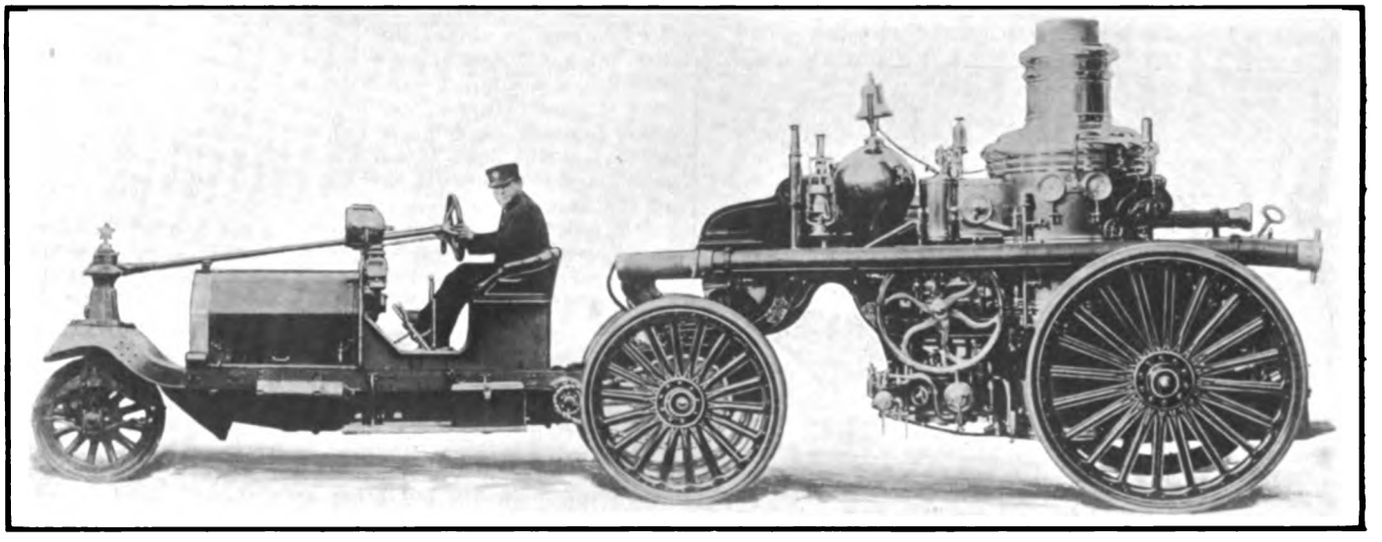
50-foot lines siamesed into one line playing into one two-inch tip. The car has a speed of 35 miles an hour and is equipped with Firestone tires, made by the Firestone Tire & Rubber Company, Akron, O.

The citizens of Auburn, R. I., endeavored to bring about the purchase of a piece of automobile apparatus last fall but the city council refused to take action. A fire broke out recently in a part of the town some distance from the station, and by the time the horse drawn apparatus reached the scene the flames had gained such headway they could not be checked and the property was destroyed. In commenting upon the blaze a local paper stated that had the department been equipped with a piece of automobile apparatus the house would have been saved, and that residents of that section are entitled to proper fire protection. It is proposed to have automobile apparatus even if the residents have to raise the money by subscription.

Mansfield, Mass., is well pleased with its installation of motor propelled fire apparatus which has been in service over a year. The cost of maintenance has been $30 and expense of operating $80, a total of $110. During the year the machine responded to 50 alarms, covering both inside and outside the fire districts and 35 of these fires have been taken care of by the squad manning the motor car. Chief King says in his report:

"Experience has fully demonstrated the fact that motor fire apparatus is the most economical, practical and efficient equipment and I hope it will not be long before appliances will be perfected so that all our apparatus may be equipped with motors." In addition he states that the flying squad has lessened by over one-half the work of the other members of the department.

Pontiac, Mich., has installed its first piece of automobile fire apparatus, the chief of the department estimating that it will take the place of three horses and that it will be used to cover the entire city. It is a combination hose and chemical wagon, made by the American-La France Fire Engine Company of Elmira, N. Y., and has been geared down to a maximum speed of 40 miles an hour. The capacity of the chemical tank is but 40 gallons, but the chief holds that if a blaze cannot be extinguished with its contents it is time to turn on the water. It is probable that other motor fire apparatus will be installed later.



The following cities and towns have made appropriations for the purchase of motor propelled fire apparatus or are considering the same: Lynn, Mass.; Riverside, Cal.; Augusta, Ga.; Akron, O.; Paducah, Ky.; Pueblo, Col.; Hillsboro, Cal.; Binghamton, N. Y.; Dallas, Tex.; Nashville, Tenn.; New Britain, Conn.; Jacksonville, Fla.; Bridgeport, Conn.; Haverhill, Mass.; Rochester, Minn.; East Islip, N. Y.; Davenport, Ia.; Ottawa, Kan.

The White Company, Cleveland, O., maker of pleasure and commercial vehicles, recently shipped two pieces of motor propelled fire apparatus to its New York office. One of the machines is a chemical engine designed for the Young America Hose Company in Poughkeepsie, and the other is for the department in Mount Vernon, N. Y. The bodies were made in Kanawha, W. Va.

Two new fire companies have been placed in commission at Washington, D. C., and one of these owns the city's first piece of automobile fire apparatus which is a combination engine and hose wagon. The different companies of the city will be instructed in the use of the machine, as it is the plan of the chief to eliminate the horse drawn equipment.

Indianapolis, Ind., which is installing several pieces of motor propelled apparatus, had a bad year in the matter of fires. With less than a month remaining of 1911 the record of fires exceeded that of the previous year by more than 100.

Leominster, Mass., will place in service shortly a motor propelled combination hose and chemical wagon, the money to purchase which was raised at a special meeting last summer. It is probable that a special driver will have to be secured as the firemen driving the horse drawn vehicle do not care to operate an automobile.

The Martin Tractor Attached to a Former Horse Drawn Steam Fire Engine, Depicting One of the Many Uses to Which the Product of the Knox Automobile Company May Be Applied.

At a recent meeting of the city council in Princeton, Ind., a member of the council moved for the discharge of a special committee appointed five months ago to buy horse drawn equipment and suggested that another committee be empowered to investigate the advisability of securing motor propelled apparatus. The motion was carried and the mayor will serve upon the committee.

William R. Tucker, secretary of the committee on municipal affairs of the Philadelphia Board of Trade, in a recent communication to Herman Loeb, director of supplies, requested the city to provide new fire apparatus for the department and modernize the service. The former director, before retirement, planned to add eight pieces of the horse drawn type, but upon the request of the Board of Trade delayed action. In his lettter, Mr. Taylor called attention to the numerous cities within a radius of 100 miles of Philadelphia that have installed automobile apparatus

MECHANICAL NOTES AND TIPS FOR DRIVERS

REMOVING TIRES FROM RUSTED RIMS.

Pneumatic tires which have been in service for considerable time and which have not been removed since being fitted, frequently give the operator trouble when an inner tube is replaced or a new member put on. This is especially true if the car be operated in all kinds of weather. Moisture finds its way between the shoe and the rim and a condition arises known as freezing of the tire. To remove one of these tires is a difficult task and the ordinary tire tools fail to start the member. If the shoe be in good condition one dislikes to try methods which would be likely to injure the casing.

An instance of a frozen shoe which resisted the efforts of the garage attendants was noted by the writer recently. The tire had been in service over 3000 miles during which time it had not been punctured or removed. About every scheme known to the workmen was tried but without avail.

An owner of a pleasure vehicle quickly solved the problem with a Fisk tire tool that is utilized with the bolted-on

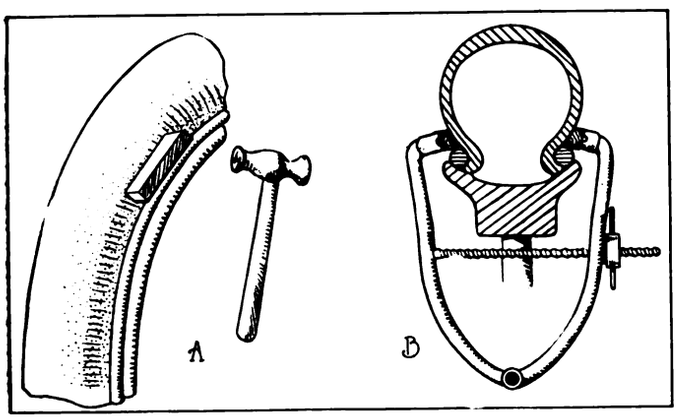

Fig. 1—Some Pneumatic Tire Removing Hints: A, Using Block and Hammer; B, Clamp for Starting Shoe Frozen to Rim.

type of casing and which is depicted at Fig. 1 B. It was clamped to the tire with blocks of wood interposed, as shown in the sketch, and when the device was operated the bead was started. A larger block of wood and a hammer were utilized as shown at A and the refractory shoe soon yielded to the treatment.

It was found that the rim was rusty and the operator decided to remove the other tires, after which the rims were sand papered and treated with a coat of graphite and oil.

IGNITION TIMING.

Although the general practise is to equip the commercial vehicle with a magneto for ignition purposes there are many cars being utilized which are fitted with timers or commutators, coil and either dry cells or storage batteries as a means of current. Others employ both systems, providing the timer or distributor for starting purposes and relying upon the mechanical generator for operating the motor.

With the former type there is more or less wear and parts subject to friction must be replaced, this depending upon the construction of the device and care given it. Frequently the operator who attends to the minor repairs of the automobile will remove the timer without considering its proper replacement, and unless he is familiar with the principles of ignition timing he will be obliged to call upon the expert repairman.

A knowledge of both valve and ignition timing will be valuable to the operator as not only will it be of assistance when overhauling the power plant, but in the event of trouble upon the road it will enable him to make the necessary adjustments and complete his trip.

By ignition timing is meant the firing and expansion, or explosion of the charge of compressed gas in the combustion chamber, not the time of the spark. There is a difference between the time at which the electricity jumps across the gap and that at which the charge begins. There is also an interval between the time of breaking contact at the timer and the ignition of the gas. This is termed a lag and to offset this the commutator is moved to bring about an earlier break, which is accomplished by means of rods connecting with a lever on the steering wheel. This is known to operators as advancing the spark. This advance may apply well where a magneto furnishes the current.

In order to obtain the greatest efficiency of the motor the volume of gas should begin to expand as the piston starts to descend; theoretically at the top of the compression stroke. Where a battery, timer and coil are utilized, there is a certain delay in the electricity reaching the plug as the current flows through first the primary and then the secondary paths before the spark takes place at the points of the plug.

This interval varies according to the number of revolutions of the crankshaft. Thus, when the motor is running at high speeds the spark lever is further advanced than at low. This setting ahead differs according to the design of the motor, also the amount of compression, density of gas charge and condition of battery, coil, etc., will have to be considered.

For example: With an engine running at 1000 revolutions a minute the spark should take place when the piston has about .625 inch to travel before completing the compression stroke. These conditions, however, do not exist when the engine is operating at a slower speed or when starting.

There are several methods of timing but the easiest for the amateur is by the piston. As cylinder No. 1 is usually nearest the radiator it can be utilized. If the former be fitted with a priming or compression cock, it is an easy matter to locate the exact position of the piston. A bicycle spoke or a piece of drill rod is inserted through the petcock as the cylinder is compressing. The latter may be located easily by opening all of the petcocks with the exception of the first member, and by turning over the motor, when the resistance will be noted.

The petcock of this cylinder is then opened and the rod inserted, and by a further movement of the starting crank the rod will begin to rise until it stops. This denotes the top of the compression stroke. The rod should then be nicked to indicate this position, and allowed to drop .5 inch; that is, the piston is permitted to descend this distance.

While this is a fairly good retard, it is safe for starting purposes and can be offset by the advance of the timer under the usual methods. Having located the position of the piston, the spark lever on the steering wheel is set back or forward, as the case may be, as far as it will go. Having fully retarded the lever the timer is adjusted so that the contact roller just touches the metal block which in turn is connected to the primary wire of cylinder No. 1, as shown in Fig. 2 A. The commutator is then locked by set screw or nut. In multiple cylinders it is only necessary to time

Digitized by Google

one as the others should be correct. They can be checked, however, if so desired.

When the motor is not fitted with compression cocks or openings permitting the use of the rod, the centres of the flywheel may be utilized. In a four-cylinder motor two pistons are up and a like number are down when on dead centres. With the explosions occurring 1, 2, 4, 3, as shown in the drawing, the piston in the first cylinder has reached the top of compression stroke and travelled downward about .5 inch, as previously explained. One centre of the flywheel has passed by the indicator as illustrated in the sketch which depicts a crankshaft revolving clockwise.

Assuming the centre mark is correct, and not being able to check the piston lead by the usual method, it will be necessary to figure it out by using the diameter and circumference of the flywheel and stroke of the piston, in order to mark off the distance on the periphery of the former. Thus, if the diameter be 15 inches the circumference would be 47.124.

As half a revolution is made to a stroke, or 180 degrees, one-half of the above figure would be 23.562, which is in turn divided by the length of travel of the piston, 4.5 inches, giving approximately 5.23 inches to be measured off on the flywheel, as indicated in the drawing. This will about equal the .5-inch down-stroke, as previously explained.

It will be well to add another .5 inch or more, unless it be accurately figured. Longer or shorter piston travel and different sized wheels may be computed on the same basis, but while this method may be utilized when the timer becomes loose while on the road, it is not recommended. Should the timer be set too early a backfire will ensue and the operator might be injured in cranking.

Where the flywheel is not marked and the rod cannot be employed, it will be necessary to remove the lower half of the crankcase or an inspection plate to determine the centres. The piston of cylinder No. 1 should be brought tc the top of the compression stroke and the rim of the flywheel under the indicator nicked or marked. A half-turn will bring the piston of the second cylinder at dead centre when the wheel should be marked. This will give the centres desired.

Having obtained these it will be an easy matter to check off the point of contact on the timer and to note it on the flywheel. All four may be treated similarly. This will also aid in timing the valves, and if the motor is a new one and the flywheel not marked, it will not be difficult to place figures on it.

Sometimes in overhauling the motor the amateur neglects to note whether the gears utilized to drive the magneto are marked. Usually the proper mesh is indicated on the teeth as shown in the illustration at B, which depicts a conventional method of assembly. If the wheel be not marked it should be with a prick punch. One tooth should be nicked on the intermediate gear and another indentation make on the other gears as indicated. One on the tooth and another against the space is the best way.

In timing, it must be borne in mind that any wear of the connecting rod bearings will alter the relative position of the flywheel to the indicator, and while this may not affect the setting of a timer to any great extent, it would alter that of the valves. To insure accurate results the timing should be obtained from the maker and by utilizing the figures on the flywheel it can be checked and remarked if necessary.

LINING UP CHAINS.

Where the chain drive is utilized, especially the single member, it is essential to line up the driving and driven sprockets to obtain the best results. Devices are provided for adjustment, but if the sprockets be suspected of being out of alignment they may be tested easily by extending a piece of string from the outside of the teeth of the forward to those of the rear member. The twine should be dropped below the top of the teeth and drawn tightly. If the string bear evenly on both sprockets it may be assumed that they are in line. A space between the twine and the metal will denote faulty adjustment and this should be remedied.

COLD AFFECTS GAS TANK PRESSURE.

The Prest-O-Lite Company, maker of gas tanks of that name, announces that the pressure of these members is affected by temperature. The correct pressure should be 225 pounds or 15 atmospheres at 65 degrees Fahrenheit. When the tank is chilled, however, the pressure drops rapidly, and a decrease of 49 degrees will cause it to drop one-half. Nine to 10 atmospheres, or from 135 to 150 pounds, in cold weather is not unreasonable. To prove the effect of temperature upon the pressure, place a tank that has been exposed to the cold in a room of normal temperature and note the results.

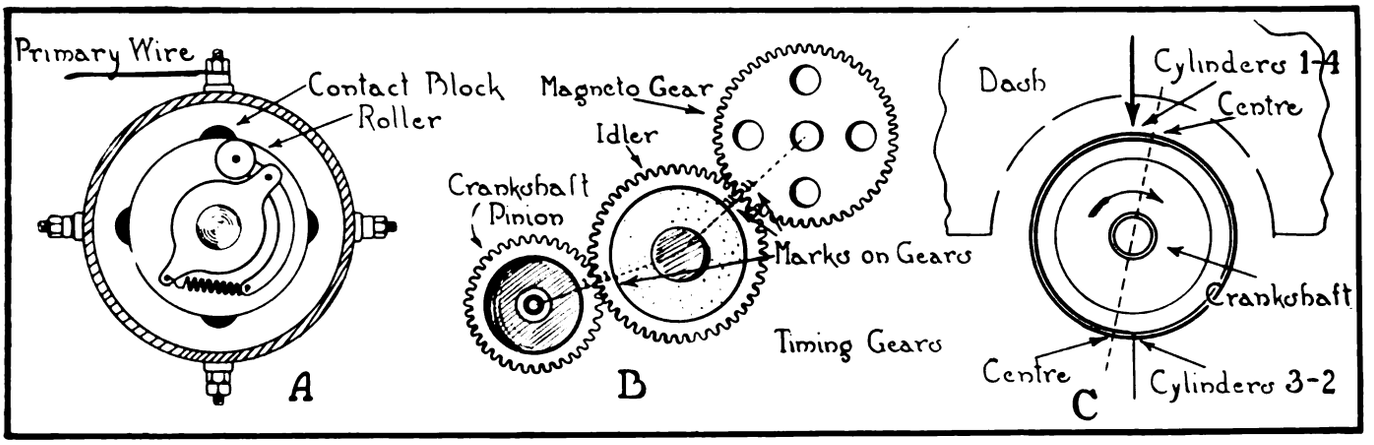

Fig. 2—Some Ignition Timing Suggestions: A, Position of Timer with Contact About to Break; B, Marking Gears Which Drive the Magneto; C, Dash Device and Diagram for Marking Time of Ignition.

KENNEDY HEADS ALCO COST BUREAU.

W. P. Kennedy has been appointed head of the transportation cost bureau of the truck department of the American Locomotive Company, New York City, and will devote his energies to transportation problems with which subject he is thoroughly conversant, having been connected with the commercial car industry for some time. He states that there is a tremendous waste of money through the failure of the users of the horse drawn equipment to systematize their hauling methods, and estimates that by proper use of the automobile a saving from 15 to 40 per cent, may be effected.

The object of the cost bureau is to analyze the various hauling systems in a scientific way and tabulate the results carefully, providing actual figures and working diagrams, and demonstrating the saving of motor cars over horses.

PUBLISHED THE FIRST OF EACH MONTH.

SUBSCRIPTIONS:
The United States and Mexico, the year, $1 in advance; Canada and Foreign Countries in Postal Union, the year, $2 in advance. Fifteen cents the copy.

ADVERTISING RATES:
Information given on request. All advertising copy must reach this office not later than the 25th of the month preceding.
Anonymous communications not considered. Correspondence on subjects relating to trucks, delivery wagons, taxicabs, tractors, all motor driven farm, fire, and municipal apparatus, the motor industry and the trade, will receive attention. Stamps must be enclosed to insure return of unsolicited contributions.
Entered as second class matter, February 25, 1911, at the Postoffice at Pawtucket, R. I., under the Act of March 3rd, 1879.

PROGRESS REVEALED BY SHOWS.

Those who have been watching the commercial vehicle side of the industry cannot help but be impressed with its importance as reflected by the present show season. A little more than a year ago, when it was decided to hold separate exhibitions for industrial transports in New York and Chicago there were many who questioned the wisdom of the innovation. They were certain that the business of producing and selling this type of motor conveyance had not progressed sufficiently to warrant the undertaking.

But the success of the truck shows, so-called, in the two big centres where the scheme was given a trial, indicated clearly that while the motor truck situation might be considered more or less in its infancy, the possibilities of interesting prospective purchasers were infinitely larger than had been anticipated. Compared with the business transacted at the pleasure car displays, the result was such as to leave no possible room for doubt that the innovation was timely and well worth continuation.

The increased representation at the two national exhibits this year is sufficient indication of the manner in which the opportunity for displaying motor trucks is regarded by the manufacturers. That they have not misplaced their confidence in the buying public is borne out by the attendance and business transacted. The industrial transport is an established institution, and the commercial vehicle show may be regarded as a permanent fixture. The production and sale of these cars no longer is an infant industry and the success of the present show season is but one of the indications of its wonderful progress.

SERVICE AN IMPORTANT FACTOR.

Last summer, during the protracted heated period, large numbers of horses were overcome in the cities, especially, and the increase in the sale of commercial motor vehicles was decidedly marked in consequence. The cold wave of the past month, accompanied as it was by snow and ice, presented still another argument in favor of motor trucks, and the buying public was not slow to appreciate its essential points. Coming in connection with the national show in New York City, it is probable that it will have a decided effect upon the business to be done in this field the coming season.

Whether or not the motor truck is able to effect a saving in dollars and cents, although this position can be proven in nearly every instance, there is the matter of service to be taken into consideration. Antequated methods of doing business must be relegated to the rear, so soon as it is demonstrated that something more modern is offered. There can be no doubt that the power wagon solves the question of service under any and all circumstances, and is not in the least affected by the weather.

When the streets are filled with snow and ice, as when the heat is so intense that horses cannot be relied upon to do their work, the motor truck covers its route as regularly as under the most ideal conditions. Those who have been accustomed to gauge their business capacity by the ability of their horse drawn equipment to meet these conditions, are compelled to realize that the firm which employs a thoroughly dependable system of delivery, for instance, secures the business which rightly belongs to them. The obvious solution is to meet the problem in the same manner as the competitor, and since the motor truck has reached a point where it can be depended upon, there is little reason for failing to grasp the opportunities presented.

MEETING THE BODY PROBLEM.

There seems little doubt that the question of bodies will be of decided moment throughout the coming season. This applies to all forms of transports, but in no case is it more true than with the smaller wagon, such as may be used by retail stores. In many instances these firms have built up a delivery system after much careful thought and experimentation, and it is hardly to be expected that they will consider the newer method of transportation without judging its effect upon this system.

It may be possible to evolve some standard types of bodies which will meet a large number of requirements, but it is a situation which calls for much careful consideration by manufacturers. It is by no means essential that the buyer shall rearrange his whole method of doing business in order to avail himself of the possibilities offered by the modern vehicle. It is necessary, therefore, for both sides to give thought to the question of bodies before determining the suitability of the particular wagon for the work to which it is to be put.

This means quite as much to the maker as to the purchaser. One delivery wagon carefully placed may mean the sale of a dozen others—perhaps many more—because there are few business men who are unable to influence their friends in this regard. On the other hand, a mistake in the equipment of one machine may be sufficient to affect as many sales in the opposite manner. The importance of the situation cannot be over-estimated.

RECENT MOTOR VEHICLE PATENTS

Valve Grinding Device.

In grinding valves of the poppet type an oscillating motion of the tool is desirable. A patent has been granted to De Will G. Vaughn, Richmond, Va., assignor of one-half to Dallas A. Shaffer of that city, for a device which embodies this feature. It comprises a shaft fitted with a worm which actuates a longitudinal sleeve and rotates the shaft. A tubular extension is provided with a bit and motion is imparted to the latter by means of a handle. Each portion of the two-part telescopic shaft rotates independently and one is fitted with a number of longitudinal slots at one end, the other member being equipped with a pin adapted to enter any one of the recesses. A spring is also attached for the purpose of separating the tubes and disengaging the connection. The oscillating movement is obtained by longitudinal pressure and release.

Electric Speed Limit Signal.

A patent for a speed limit signalling apparatus has been granted Fabius M. Butler, David City, Neb., which is operated by electricity and rings a bell when an indicated speed is reached by the vehicle. The dial of a speedometer is fitted with contact members as is another part, these being connected electrically. When the indicating hand of the speedometer touches the 10-mile contact, for example, the current flows to the bell. A lever is attached to the regulating device and may be set to sound an alarm at any desired speed. This arm is connected to a visible index, which shows but one number at a time, and is provided with an electric lamp.

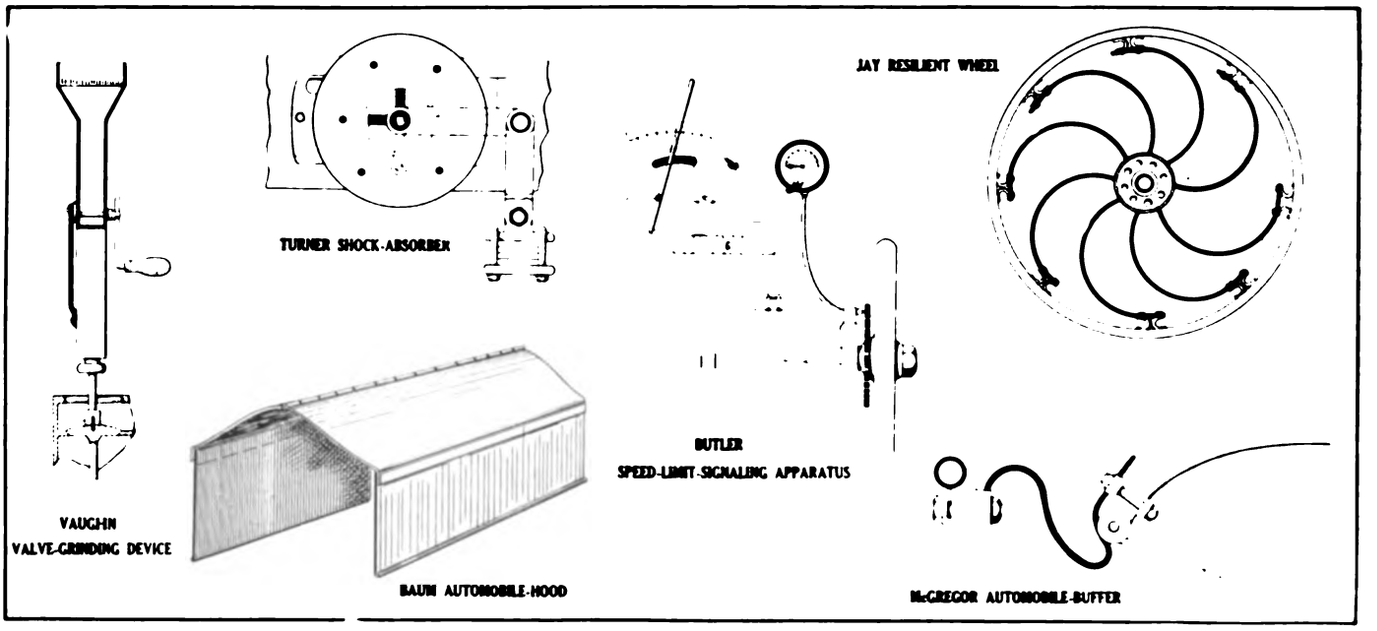
Automobile Hood.

An automobile hood so constructed that its hinges are joint tight and weather proof, has been designed and patented by Henry G. Baum, York, Penn., assignor of one-half to the Pullman Motor Car Company of that place. The close joints are obtained by every alternating lip of the members being rolled backward upon itself to engage a binding or pivot rod, and the remaining lips extending under the surface of the corresponding rolled members.

Resilient Wheel.

Isaac Jay, Pendleton, Ore., has been granted a patent for a resilient wheel, the rim of which is fitted with a number of U shaped pieces in pairs and to these are bolted one end of eight curved spokes. The other ends of these members are attached to the hub by plates and bolts.

Automobile Buffer.



A novel form of automobile buffer designed for motor vehicles operating in heavy traffic, has been patented by Allan L. McGregor, Chicago. The buffer bar is carried in clamps which are slotted and locked by a bolt and nut. To this member is attached one end of the two S shaped springs. The other ends are fitted to clamps bolted to the frame extension in proximity to the spring.

Turner Shock Absorber.

A shock absorber operating on the friction principle has been patented by Harry C. Turner of Los Angeles, Cal. It consists of a stationary case with a revoluble sleeve mounted therein, and an arm attached to rotate this. The extension is pivotally mounted and connected with a similar member fastened to the spring. The interior of the case carries a ratchet member which is fitted with a number of spring pressed dogs, which engage it and rotate another movable part. This is fitted with friction plates which operate in different directions. Contact between the stationary plate and friction members is maintained by an annular spring between a screw cap and stationary disc.

MONTREAL SPACE IS LIMITED.

The week of Feb. 3-10 has been selected as the date for the annual national Canadian automobile show in the Drill Shed at Montreal. The demand for space has exceeded all previous records, and Manager E. M. Wilcox is having trouble trying to locate many who desire opportunity to make display. A number of vehicles will be shown in Canada for the first time at this exhibit.

Some Recently Patented Ideas of Inventors of Interest to the Manufacturer of Commercial Vehicles and Allied Trades.

New Commercial Car Accessories

Patton Safety Starter Crank.

The Patton safety starter crank, being marketed by the Patton Crank Company of Chicago, is designed to eliminate any possible danger of cranking and is so constructed that the slightest kick will release its locking mechanism. The instrument is similar in appearance to the ordinary member, which is removed when the Patton is fitted, the operation involving but the drilling of a small hole and the driving of a pin. It is claimed that there is nothing to adjust, as springs, cogs, ratchets, pawls or friction clutches are not employed.

Quick Detachable Rim Remover.

A device for facilitating the removal of the locking rim used with Universal or Firestone quick detachable tires has been invented by William L. Tobey, East Boston, Mass., and the instrument is very compact and inexpensive. It consists of a flange which fits over the rim, carrying an adjustable bolt with a slotted head. The tool is inserted at the joint of the locking ring and by turning the threaded member the clincher ring is forced from position as denoted in the dotted lines of the drawing. This permits of easy removal of that member. In replacing a tire the inner tube may be inflated enough to prevent possible pinching, and the ring attached by the tool. The latter is case hardened and nickel plated, and weighs but 2.5 ounces.

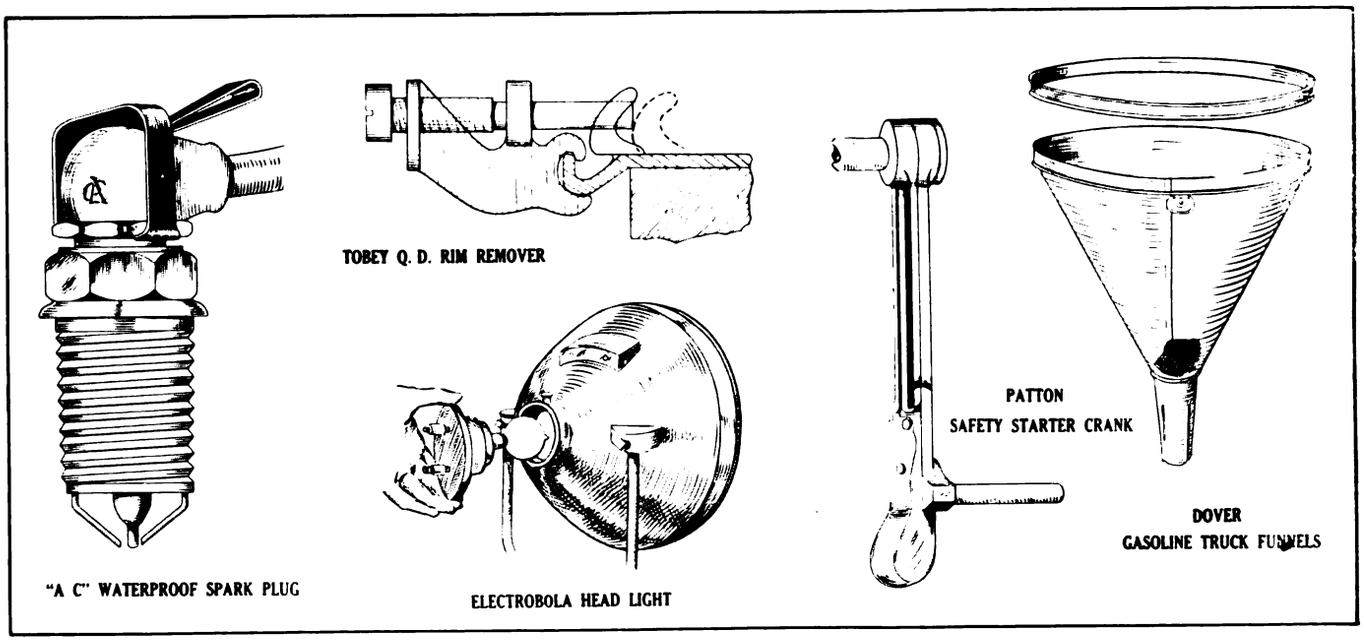
Dover Gasoline Funnel.

A new gasoline funnel has been brought out by the Dover Stamping & Manufacturing Company, Cambridge, Mass., and is especially adaptable for commercial vehicles. The device is made of extra heavy galvanized steel and designed to withstand hard service. The spout is larger than the standard funnels and is seamed to the body, not soldered, this arrangement eliminating the danger of breakage. The spout and lower part of the body are beaded so that they will not become airbound in any size opening. The funnel is fitted with hoops to hold the chamois and is also equipped with fine brass gauze for filtering purposes. The device is made in two sizes, four and eight quarts, respectively.

A. C. Waterproof Spark Plug.

Moisture and water seriously interfere with the proper operation of the spark plug and to prevent the high-tension current from taking paths other than intended the Champion Ignition Company, Flint, Mich., has brought out a unique type of waterproof plug. This feature is obtained by the design of the member itself, instead of by extra fittings. A coiled wire or spring leads from the centre electrode and forms a connection with the end of the high-tension cable which fits into an opening in the porcelain hood. The latter has a horizontal projection about .75 inch long, and there is no chance for the water to short circuit the plug. The hood, which is held by a clip, is fitted with a threaded tube into which the wire is screwed tightly. A feature of the plug is that after the hood is removed there is no exposed insulation to be broken by careless handling.

Electrobola Lamp.



Electric lighting on the commercial vehicle presents a saving in time, which is an important factor in motor truck operation. The Electrobola Lamp Company, Milwaukee, Wis., is manufacturing a practical lamp for such service, permitting as it does the replacement of a broken bulb without unlocking the door. The bulb is fitted to a socket which is equipped with outside connections for the wires, and is locked in position by a screw. The lamp is a one-piece aluminum casting with the interior highly polished, and is claimed to be dust and moisture proof and that it will not tarnish.

ST. LOUIS IN FEBRUARY.

Although the dealers in St. Louis, Mo., already have held one display of 1912 models, this having been held in the open air last fall, plans are under way for two more in February. The second week, Feb. 12-17, will be devoted exclusively to commercial vehicles.

BIG DISPLAY FOR ATLANTA.

Not since the national show of Nov. 6-13, 1909, has Atlanta, Ga., held an automobile display. This year, the Atlanta Automobile & Accessory Association has been organized for the purpose of holding an exhibition in the Auditorium armory, Feb. 10-17. Coming so soon after the close of the Chicago show, it is anticipated that a large number of the exhibits at that display will be sent direct to Atlanta. Special provision has been made for commercial vehicles, and the present interest in this type of transport throughout the South is sufficient indication that this section will be well patronized.

THE A B C OF MOTOR TRUCK OPERATION.

A Simple Exposition of the Principles Underlying Operation, Maintenance and Repair of All Motor Driven Commercial Cars, Outlining Details of Components. Part XV---Necessity of Speed Changing Devices and Their Forms.

By Morris A. Hall, M. E.

EVERY gasoline automobile must have a speed changing device of some form because of the principle upon which the motor operates. As previously pointed out under the heading of clutches, the internal combustion engine has a certain well defined limiting power output, which may not be exceeded or even approached without danger of stoppage. In the ordinary use of the car, running along the road where stops are necessary or in the exigencies of city traffic, this speedily is apparent. Whenever the machine is started, either from rest or from a pause or delay which has induced slower speed, it becomes necessary to lighten the load on the motor.

This may be done by slipping the clutch and speeding up the engine, then letting the former in very gently, or as is the case more often, by changing down to a lower gear so soon as the rate of crankshaft rotation must be checked. The latter method gives the engine an advantage in that the lower the speed of car through its gearing, the greater the amount of power delivered at the road wheels. Although the engine maximum output remains unchanged, these different methods of using it give the equivalent of a much greater amount of power.

To prove this by means of a practical and everyday example: Take an engine which develops 40 horsepower and is used in a car, the three forward speeds of which give respectively, 3.2, 5.3 and eight gear ratios; that is, on these various speeds, the motor will turn 3.2, 5.3 or eight times to one of the road wheels. The power exerted at the wheels varies in the exact ratio of these three figures, developing the least when the first named is in force, more with the second combination, and the most when the third or low speed mechanism is engaged. Obviously, when the load is light, the highest ratio will be utilized in order to bring forth the great speed which this also gives.

When the load is much greater as on a steep hill or through deep sand or mud, speed is undesirable but actual, certain progress is needed, hence the change is made to that relation of the gearing which produces more power at the wheels. Similarly, when the sand becomes too deep or the hill too steep for the first reduction, the third gearing is resorted to in order to bring about the maximum of which the vehicle and motor in combination are capable, although some cars are equipped with a four-speed transmission, which will give an even lower reduction.

It has been explained that starting a car throws onto the motor the biggest load of all, as by the laws of friction the greatest amount of power is required to start a body from a state of rest, having in mind that necessary for maintaining it in motion. For this reason, the truck is always expected to go away from a standstill at its slowest speed, passing to a higher rate only as it gains momentum, when less power is required to propel it and more of the available engine output can be converted into speed. This is true of all cars, regardless of size or type, but the greater the total load, the lower must be the starting speed, and the longer must the accelerating process be prolonged.

The reverse of this last statement is equally true; the lighter the whole weight carried, the more easily and quickly may the vehicle be brought up to a high rate of travel. In fact, on very light cars in the hands of expert drivers, it is not always necessary to change down to the lowest speed for starting, this being accomplished on the second or intermediate, as it is called.

However, the exigencies of starting and stopping do not constitute the sole function of the speed changing gear or transmission. There are for instance, those who do not wish to travel fast. With a car which is capable of say 50 miles an hour with the above mentioned gear ratio of 3.2 on the high, it might be that it is desired to go no faster than 30 miles an hour. In this instance it would be possible to choose between slowing the motor down until on the high gear this rate was produced, or of changing to a lower speed and letting the engine maintain its high rate of travel.

This argument might be said to refer specifically to pleasure cars, but with commercial vehicles the various speeds are even more necessary. Take a vehicle of one ton capacity designed to travel at a maximum speed of 25 miles an hour. If this were used in an emergency to carry 2800 pounds, no such speed would be expected of it. On the contrary, more power would be needed simply to keep the car in motion with the heavier load, necessitating, as previously pointed out, a lower gear reduction, or as it is commonly called, a lower gear.

In the transportation of goods, the reliability of delivery is of greater value than the actual time consumed. So, although the commercial car has a sustained speed two or three times that of the horse, certainty of arrival at its

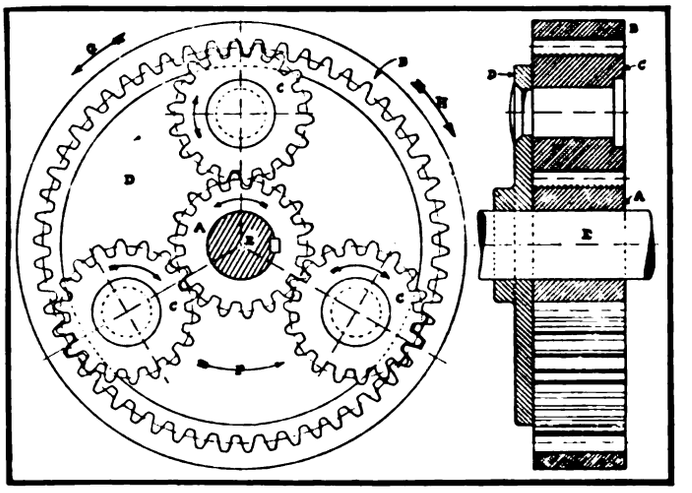

Fig. 61—Sketch to Illustrate Action of Planetary Transmission, Used on Many Low Priced Delivery Cars.

destination is of equal or greater import. Where there are hills, bad roads or pavements, ice or snow, or other possible obstructions, the vehicle must have sufficient power on the lowest gear to extricate itself. In short, this means that on a commercial car the slower speeds are of even greater value than the higher. It is for this reason that four and five-ton trucks often are found with a low speed of 3.5 and four miles an hour, when ordinary city usage would call for about twice that as a minimum; the maker cannot afford to take any chance and must gear his vehicle to a point where he and the buyer are absolutely safe.

These basic principles apply whatever the type of transmission; in fact, the latter does not enter into the discussion until later, although as will be pointed out then, the form which gives the greater number of possible speed changes would be fitted to commercial work best of all, other things being equal, for then the peculiar combination of the greatest pulling power with the highest speed can be evolved for each individual instance. However, this is a more or less ideal combination and one which is not realized in practise even by those devices designed for that specific purpose.

Digitized by Google

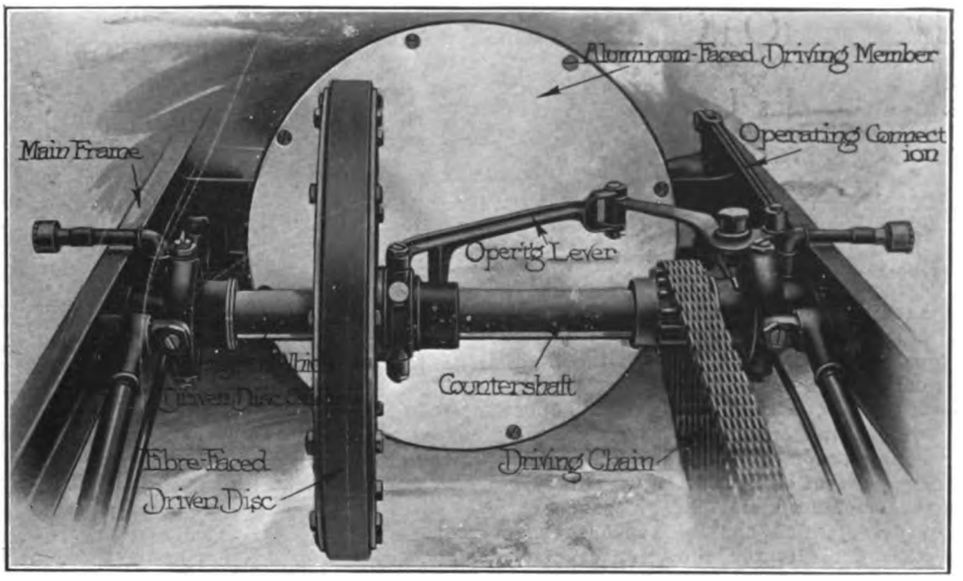

Fig. 62—Friction Form of Speed Changing Device for Commercial Cars, Showing Components and Materials Used.

Generally speaking, all forms of speed changing devices are available for commercial work, although there are inherent reasons in each one now in use which fit it best for some particular division rather than for all. There are four types of mechanism available and now used for this service: The planetary or epicyclic form of gearing; the friction transmission; the more usual sliding gearset, and the fluid devices which may be said to include as well electrical transmissions. There is a possible fifth class, in which might be placed the flat leather belt drive with a series of tight and loose pulleys and belt shifters, etc., but these may be dismissed as having gained no permanent place as yet.

The planetary transmission derives its name from the grouping of its gears in the form of a sun and planets surrounding it; in fact, the correct name for it a number of years ago was sun and planet gearing. Stated broadly, there is a central driving member, around which are grouped two, three, four or more sets of pinions, driving from it. If the two were of equal size and the planets fixed in position, there would be no difference in number of revolutions or power developed. On the other hand, when the pinions are larger than the driving gear, as is always the case, the former are rotated at a slower rate than the latter. This is when all are held in position, but when the planets are allowed to travel as a unit around the central member, a double motion is gained; one part from the drive by gear to gear, the other from the rotary movement. According to the direction and manner in which this occurs, it is either additive or subtractive. That is, when moving around in the same direction as the driving gear, a higher speed than when standing still is obtained, but if by a combination of gears and other parts, motion in the opposite direction or against the rotation of the driver be obtained this may be slower than when the planets stand still as a unit. By carrying the latter to an extreme, an entirely opposite or reverse motion may be obtained, which is the case in the usual automobile or motor truck transmission of the planetary form.

A sketch of a gear of this type is shown at Fig. 61, in which the pinion A is connected to the crankshaft of the engine or clutch shaft as the case may be, and drives the others. The three planetary gears C revolve freely on their spindles or shafts which are fixed in the plate D. The drive is taken from the latter by means of shaft, chain or otherwise. When the internally toothed ring B is held and the pinion A revolved, the planetary members are caused to run around the ring and carry the plate with them in the direction of the arrow marked F; that is, in the same direction as the driving gear. The speed, however, is altered. This is equal to the ratio of the number of teeth in the pinion to those in the ring plus one gained by the enforced left handed rotation around it. In this case, A has 18 teeth and B 54, hence the speed reduction when the latter is held is as 18 to 55 or 3.05.

If the internally toothed member B be forced to act as the driver of the set, it is apparent that the resulting direction of rotation of the gear A will be opposite to the final movement as just described or rather as indicated by the second arrow H. Moreover, so doing it will gain speed through the double motion imparted to it; one by the revolving of

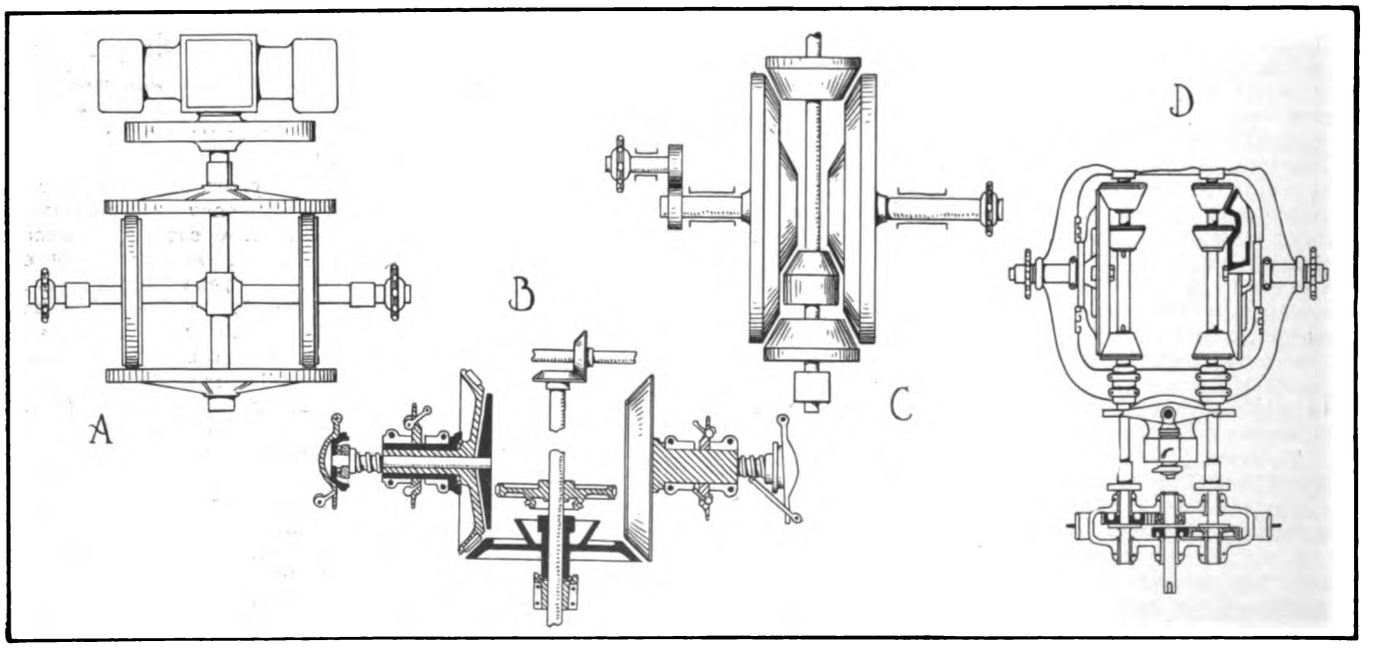

Fig. 63—Four Differing Types of Friction Transmissions, Bringing Out the Use of Spur and Bevel Discs and Combinations of These.

Digitized by Google

the gears C, and the other by the motion of the planet as a unit represented by the plate and gears. In this case, the increase of speed would be as 54 minus one to 18, or 2.94 ratio.

In those modern gears in which the internally toothed member is used, the planets are arranged so as to have upon each spindle a second gear larger or smaller than the first and meshing with an additional central gear of corresponding size, the whole in a plane parallel to that of the set shown and the planets carried in a plate like D with an external drum on which is a band for gripping it and thus producing one speed. The internally toothed member also has a wide external face fitted with a second band, while a form of clutch is used to clamp the whole, pinion, planets and internal gear, tightly together so that they rotate as a unit without any diminution of speed. This produces the high rate, the holding of the internal gear as first described, the slow, and the gripping of the plate D carrying the planets, the low speed.

A little study will show that holding the plate D, when the pinion A drives and there is a secondary gear to take the final drive but no internal gear, is equivalent to the second case, in which above, it was supposed that the internal member was the driver and the result an increased speed. Inverting this and holding the plate will give a lower reverse speed in the ratio mentioned, 2.94. In practise, the pinions are selected so as to make a greater difference between the low and reverse speeds than this example would show.

This is the usual American form, the internal gear having been abandoned a number of years ago for several reasons. Chief among these were its first cost, which was high, with a correspondingly high replacement charge when this was broken. A point which might be mentioned before leaving the subject is that the number of pinions can be equally spaced only when this number will divide the teeth in the pinion and those in the internally toothed member exactly. In the case shown, three can be used but four could not. With the other more widely used form, the design is not subject to these limitations.

Friction transmissions produce power through the surface contact of one revolving wheel and another which it is pressed against and thus, forces to turn. Usually, the combination is such that the large flat face of the driver contacts with the narrow edge of the driven member, the position of the latter out from the centre of the former determining the speed. This is apparent when it is considered that the revolving disc has varying rates of surface travel from the centre where it is zero out to the edge which turns at the maximum rate. Obviously by placing the driven disc at either point it will be given one of these two speeds, and in the positions between, all of the possible variations.

The discs are held in contact by means of strong springs or are forced together by a mechanical device such as a toggle lever combination. Usually, the driver is movable, the ordinary clutch pedal being used to actuate this. Another pedal or lever moves the driven member across, this combination effecting the speed changes. One of these is shown in Fig. 62, which depicts the Lambert device. This is viewed from the rear or driven end and looking directly onto the driver. As marked, the latter is an aluminum faced unit, while the driven disc has a fibre friction face. The other details will be found self-explanatory.

Although this is the more usual form, it should not be thought that it is the only one. In fact, there are many different combinations, some utilizing the so-called spur wheel, others the bevel forms, and a number, both. In

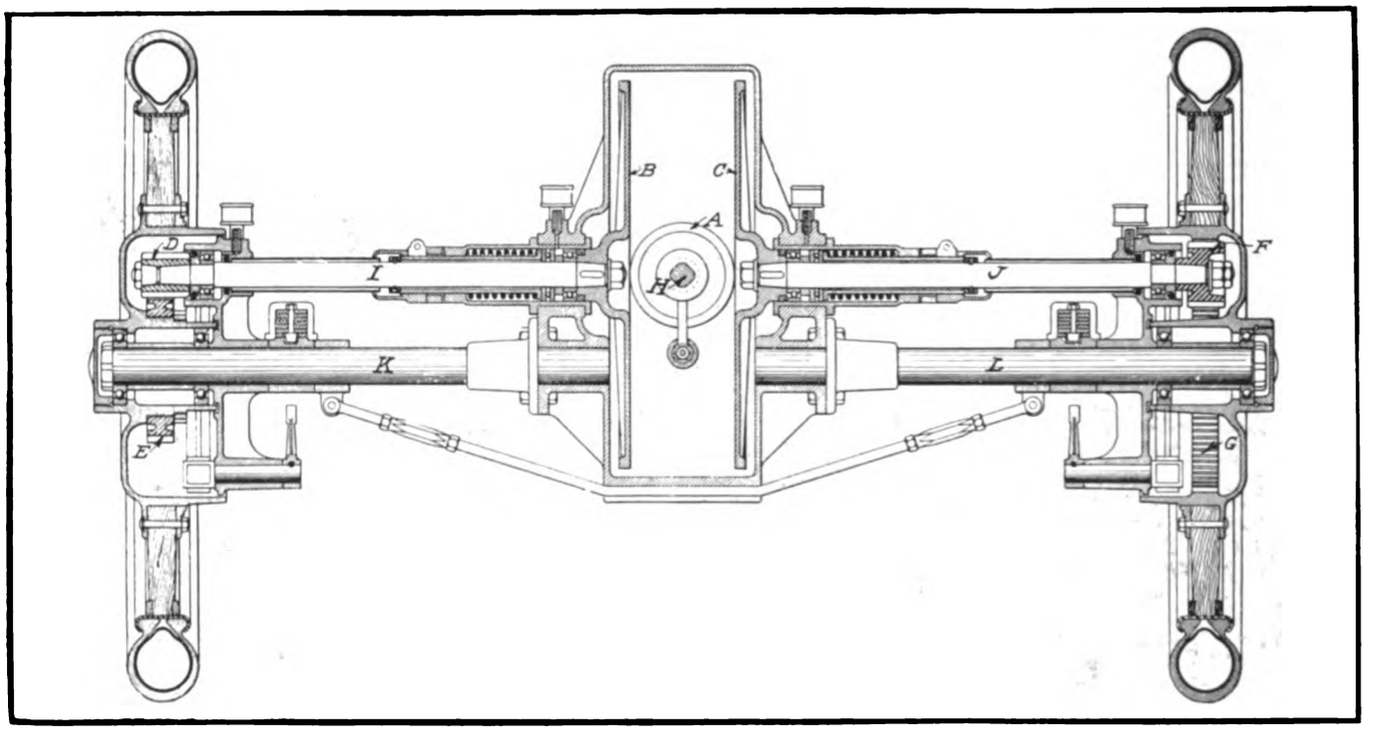

Fig. 64—Rear Axle and Friction Transmission of a Well Known Commercial Car, Showing Some of the More Important Structural Details.

Fig. 63 a group of these is shown, that at A being a four spur wheel combination. This is made in two different types, that shown being that in which each member parallel to the drive shaft contacts with but one at right angles to it, the two halves of the driven shaft being separate. The forward driver turns the right hand disc and the back member the left hand unit, both in the forward direction. In the other type, not shown, the forward disc turns both driven parts on speeds ahead and the one at the back drives them for reverse. This causes the two ends of the countershaft to turn in opposite ways, hence one of them must carry an additional spur gear arrangement to change the direction of motion so as to agree with the other.

At B is shown a combination of spur and bevel types, in which there is a direct drive on the high gear, no frictions being in contact then. The normal drive is from the engine to one bevel which propels the other two. This would give but one speed with the high making two, so the spur is introduced to produce a large number of additional variations.

The forms at C and D are of the all bevel type, a number of these being used to produce the required list of speeds in each direction. In both types, the gear reduction to

Digitized by Google

produce both speeds in the same direction at the final points will be noted. In C this occurs back of the transmission and in D ahead of it.

Fig. 64 depicts the entire rear axle and transmission construction of a car, in which the speed changing device is of the friction type and incorporated with the final drive on the rear axle. In this, H is the driving shaft, which carries the slidable member A, contacting with both B and C. The former is fixed to the shaft I, with the gear D at its outer end. This is of the spur type and meshes with another similar member E turning on the axle K. The other disc C drives the shaft J which has the spur gear F meshing with the internal gear G, through which motion is transmitted to the half axle L. By using the spurs on one side and the internally toothed member on the other, both wheels are driven in the same direction. The springs which allow of separating B and C so as to shift A back and forth readily for speed changing will be noted.

Ed. Note—The next installment will take up the various other forms of transmissions, including the sliding gear, in both progressive and selectively operated types, etc.

MARTIN TRACTOR HAULS COAL WAGON.

After subjecting the Martin tractor, the invention of Charles H. Martin, to a series of severe tests which occupied some months, the Knox Automobile Company of Springfield, Mass., displayed the device at the New York show, where it attracted considerable attention. The tractor is so designed that it may be attached to the front axle of any horse drawn vehicle, and in the accompanying illustration is depicted the device hauling a coal wagon. When thus fitted the five-wheel combination is said to take up less room than were the animals attached.

Mr. Martin devoted considerable time to the haulage problem, and the device is the result of much study and experimenting. He claims that it will effect a great saving over the conventional motor truck design on account of its first cost being about one-half of the motor car of the same capacity, while the upkeep will be proportional. In addition, the possibilities for its use in connection with a fleet of wagons gives it a corresponding economic value.

The tractor consists of a frame supporting the power plant, and transmission machinery, which is geared to the front wheels and axle of any horse drawn vehicle. It is provided in front with a single wheel for steering, this being necessary in order to swing the frame, which corresponds to the pole of the wagon, to the right or left just as horses would. The arrangement of the wheel is such that it can be turned at an 80-degree angle, and among the advantages emphasized is that it is possible to obtain a shorter turning radius by its use.

Among other claims advanced by the designer are the following: That it eliminates many of the complications of conventional motor truck construction, while it gains in efficiency as it saves maintenance charges due to excessive vibration on stiff springs, the engine and working parts being carried on springs as resilient as those fitted to the pleasure automobile, and that it saves the cost of rubber tires since it utilizes steel members.

Among the possibilities of a motor vehicle of this type is that of serving a fleet of the horse drawn type. Assumthat a large quantity of material was to be conveyed from the base of supplies to a point several miles away, and that five double-horse teams were formerly employed in the transportation. By utilizing one tractor it could be made to serve them all by disconnecting the king bolt of one of the horse drawn wagons and raising the body when the motor propelled vehicle would be free to be attached to another body which had been similarly treated, and loaded. In this manner the automobile would be kept in constant service and considerable time saved in hauling the material.

MANY DELIVERY CARS ON COAST.

H. O. Smith, president of the Premier Motor Manufacturing Company, Indianapolis, Ind., who returned recently from a visit to the Pacific Coast, states that he was very much impressed with the large volume of business transacted with the aid of motor delivery wagons. Cars capable of carrying a load of 500 pounds to 1.5 tons are favored, and these are more extensively used than in the East.

Martin Tractor, Produced by the Knox Automobile Company, by Means of Which Horse Drawn Vehicles May Be Utilized.

GENERAL MOTORS HAS NEAT BULLETIN.

The General Motors Company, Detroit, recently mailed to its agents and customers, an unusual bulletin. It was appropriate of Christmas, depicting as it did, Santa Claus driving a G. M. C. truck loaded with toys which were tagged with names. The bulletin was printed in colors and contained a modern adaptation of "The Night Before Christmas."

LUCE CONFERS WITH COMMISSION.

Morton H. Luce, chairman of the signboard committee of the Chicago Motor Club, was in Boston recently conferring with the Massachusetts highway commissioners relative to data to assist the State of Illinois in posting road signs. Mr. Luce is manager of the Chicago branch of the Velie Motor Vehicle Company, Moline, Ill.

FURTHER DISCUSSION OF ANTI-FRICTION BEARINGS.

Mr. Thomas Remains Unconvinced That Mr. Page Is Correct in His Position Regarding Worm Gear Mounting—Mr. Younger Gives Decisive Support to Mr. Thomas' Argument.

OPPORTUNITY was offered in the last issue of MOTOR TRUCK for H. Kerr Thomas of the Pierce-Arrow Motor Car Company, Buffalo, N. Y., and Victor W. Page of the New Departure Manufacturing Company, Bristol, Conn., to discuss their differences of opinion regarding the use of anti-friction ball bearings in connection with worm gearing. Mr. Thomas criticised certain statements made by Mr. Page in an article on this subject which appeared in the December number, and Mr. Page made extended reply thereto.

It would appear from the correspondence below, that Mr. Thomas is still far from being convinced that Mr. Page's position is correct. The controversy is made even more interesting by the appearance of a letter from John Younger, also of the Pierce-Arrow company. MOTOR TRUCK feels that its readers will be sufficiently interested in the matter to warrant presentation of both communications.

Editor, MOTOR TRUCK:

Sir:

Mr. Page's pungent criticisms of my observations on his original article compel me to ask you for further space in which to reply.

Mr. Page considers I place too much reliance on the experiments of Beauchamp Tower, showing friction decreasing with increase of power in the case of journals with oil bath lubrication, and in support of this he exhibits a table showing how that authority found the coefficient of friction rose with increased pressure in his experiments with very restricted drip feed. The two cases are entirely dissimilar since no one will attempt to run any worm gear without continuous and copious lubrication. Why then bring in the question of friction between dry surfaces? We are not discussing cone clutches, and as to uncertainty of lubrication, I will say at once that if there is any uncertainty about it such gearing will not work at all. It is usual in well designed axles to make them oil tight so that there need be no fear of any oil leakage but under no circumstances are both worm and wheel immersed in oil when stationary. Lanchester placed his original worm beneath the wheel, insuring the point of contact being covered with oil. The majority of designers have, however, the worm on the top and the teeth of the wheel form buckets which carry the oil to where it is wanted. If Mr. Page has the curiosity to open the cover of such a gear when it is running even slowly, he will see that the worm is running in a perfect oil bath and is itself almost invisible by reason of the stream of oil flowing over it.

Mr. Page makes one statement, however, which with every respect, is firstly incorrect and secondly, misleading. He says: "Lubricant cannot be introduced between bearing surfaces if the oil film pressure is greater than that of the head of the feed." Surely this is not what he means. If so, how would an ordinary line shaft bearing receive any oil from a syphon, when the bearing pressure is, say 200 pounds a square inch, and the oil is fed in under the pressure due to perhaps 1.5-inch head?

The correct answer is given in Mr. Page's own drawing (Fig. 1) where the rotary shaft is shown sweeping the oil round from the inlet to the load side, where the globules of grease spread out in a layer which causes actual separation of the two surfaces. This is even more noticeable in worm gearing where the contact is made between two convex surfaces sweeping over each other and carrying the lubricant between them.

I must plead innocent of having formulated any theory regarding friction—in the first place, I embraced Unwin's theory, and acknowledged it fully in my former letter; it is, however, a fact that a great deal of research has shown me (as indeed might have been anticipated) that it is correct. Nevertheless, some acquaintance with the elementary principles of machine construction has hitherto prevented me from attempting such an absurdity as increasing bearing pressure to eliminate friction, which is the reductio ad absurdum of Mr Page's argument in following out which he has confused the effects of friction with its coefficient in a specific case.

Mr. Page's quotations from Mr. Alford have no direct bearing on the subject as they refer to collar bearings, which I had never mentioned, as they are outside the scope of any remarks on automobile worm gearing. I have never advocated their use.

Next with regard to methods of mounting: I have nothing to add to my former remarks. I unhesitatingly say that while a worm spindle may work well with a thrust bearing at each end, it is more likely to do so if both thrusts are placed at the rear with provision to expand at the opposite end. Mr. Page's calculation shows that with 200-degree temperature rise, the worm may expand .01 inch, and as it should be mounted without any end clearance, this, if it took place, would make it dangerously tight; at the same time, I have never heard of such an extreme temperature rise taking place, and the relative expansion between worm and case is much less than the calculated figure; I agree with Mr. Page that the arrangement shown in Fig. 9 ought to be entirely satisfactory.

Next with regard to end thrust: I really must maintain that Mr. Page has seriously underestimated this and has, moreover, misunderstood my remarks. Let me endeavor to make the matter clearer.

The maximum pressure which can occur on the periphery of the worm wheel is that which will nearly cause the road wheels to skid when the car is fully loaded. This skidding may be caused by: (a) sudden application of engine power; (b) locking of brakes if fitted on the transmission shaft.

Take the case of a five-ton truck, the loaded rear axle weight will be say 16,000 pounds and the coefficient of friction between tires and road is say .625, making the resistance between road and wheel 10,000 pounds. The radius of the road wheel being say 20 inches, and that of the worm wheel say seven inches, the pressure between worm and wheel teeth will be

$$\frac{10{,}000 \times 20}{7} = 28{,}500 \text{ pounds}$$

not very far removed from what Mr. Page calls my "guess" in my last letter. Nearly all of this load has to be carried on the thrust bearing of the worm, but fortunately this force does not exist when running at a very slow speed; in fact, as stated above, just before the wheels begin to slide over the road either from the application of too much power to a stationary, or too much brake effort to a moving vehicle; consequently we do not have to provide a ball bearing 18 inches in diameter, as Mr Page naively suggests, to carry such a load at 250 revolutions a minute.

Coming to Mr. Page's last three paragraphs, I have re-read my former letter. There is nothing I said which could by any stretch of imagination be supposed to indicate a preference on my part for plain collar thrust bearings and I must directly contradict Mr. Page when he says I stated such bearings have longer life the more load one puts upon them. With the absurdity of such a statement, I cordially agree, but the statement is Mr. Page's—not mine—and having built worm driven axles for the last five years, which have been not unattended with a measure of success, I can assure Mr. Page that such experience as I have gained in that time is not the result of the "so little reflection" he supposes nor is the successful designing of worm gear to be achieved by "the little use of pencil and paper," intelligent or otherwise, or even by the reference to the few formulae and tables which appear to have led Mr. Page into paths which have not hitherto been followed by those designers of worm gearing who have been responsible for bringing it to its present state of perfection.

Yours truly,

H. KERR THOMAS, A. M. I. Mech. E., M. S. A. E.

Buffalo, N. Y., Jan. 19.

Editor, MOTOR TRUCK:

Sir:

The use of worm gearing on all kinds of horseless vehicles being an obsession with me I hasten to jump into the fray of discussion engendered between Messrs. Page and Thomas. My excuse for troubling you in the matter is that since 1905 I have been engaged with the premier firm in England designing and manufacturing worm driven trucks and pleasure cars, and feel entitled to say that I know what I am writing about.

I would have forgiven Mr. Page for his first article insomuch as he was carried away by his enthusiasm for the particular bearing in which his interests are bound up. But his onslaught on Mr. Thomas' entirely justifiable criticism places matters in another light, and I hasten to add my quota in support of Mr. Thomas.

Instead of taking some pencil and paper I would advise Mr. Page to spend a few dollars in some correspondence course and make acquaintance with some of the more elementary rules of mechanics. Newton's fundamental law states that action and reaction are equal and opposite. That is, if there is a thrust at the road contact of an automobile rear wheel, there is a corresponding but opposing thrust in the mechanism. In the case of a driving rear axle the thrust at the road contact is balanced by the thrust of the worm spindle, which in its turn is prevented from rotating the axle casing by means of a suitable torque rod.

Taking Mr. Page's figures as given in your issue of December we have

40 H. P. delivered at worm spindle at 1000 rpm of motor = Ratio of reduction.

Digitized by Google

Reverse 32—1 giving 328 ft. per minute travelled.
Low 24—1 giving 440 ft. per minute travelled.
Second 16—1 giving 655 ft. per minute travelled.
(Assuming a wheel diameter of 40 inches.)

The next step is to state that the efficiency of the worm gearing neglecting the bearings is about 95 per cent., not 85 per cent., which is the efficiency of the whole rear axle with bearings. (I am neglecting the bearings because I am only considering the action between the forward end of the worm spindle and the rear end where the thrust is taken, and it is unnecessary to take losses into your calculation when you know they have to be eliminated afterwards.)

Therefore we have effective horsepower 38, and the sum of the two pushes at the rear wheels assuming, as will be the case, that the motor will be working to capacity, are:

$$\text{On Reverse } \frac{38 \times 33000}{328} = 3800 \text{ pounds.}$$

$$\text{Low } \frac{38 \times 33000}{440} = 2850 \text{ pounds.}$$

$$\text{Second } \frac{38 \times 33000}{655} = 1920 \text{ pounds.}$$

Now this is at 20 inches radius, and on the principle of leverage this is increased in proportion to decrease of lever; i. e., in proportion 20 to 6 (radius of worm wheels) so that these thrusts resolve themselves thus:

Reverse 3.33 × 3800 equals 12600 pounds.
Low 3.33 × 2850 equals 9500 pounds.
Second 3.33 × 1920 equals 6400 pounds.

These pressures are approximately 10 times Mr. Page's, and these are not guesses, but the result of definite, cold-blooded logic, which my years of experience has proved to be right.

The type of bearing recommended by Mr. Page is obviously unsuited for such thrusts as I have determined above unless made in sizes like 12 or 15 inches diameter. Mr. Page has to my mind attempted to use second hand experience of worm gearing on pleasure cars or possibly light trucks to design a suitable gearing for heavy trucks. There is, however, one most important and vital difference which is only run across by experience and it alters the whole complexion of the case.

Mr. Thomas' calculation of 30,000 pounds is evidently based on braking pressure under maximum conditions, and is so exceedingly close to what can be reached under certain conditions that it is no guess but a fact.

Mr. Page assumes much indignation that anyone should dare criticise him, but he has been caught napping in something more simple than mathematical abtruseness. On page 471, December issue, he states that even with the worm installed above the worm wheel it is almost impossible to obtain the desirable 12 inches ground clearance. On page 64, January, he forgets all this and states that where large traction wheels are fitted as on the motor truck, the worm can be housed very easily under the axle as the requisite ground clearance can be obtained very readily. Which statement are we to believe, as really 40-inch driving wheels are quite large sized wheels and obtaining conditions do not warrant us placing on larger?

In all my experience of worm gearing, confined almost entirely to the overhead type I have only seen two failures due to want of lubrication—one was where the oil plug at the bottom of the case was opened in some manner and the oil ran out unnoticed, the other was due to oil having been forgotten after reassembling. It is an actual fact that even in the overhead type of worm gearing, lubricant is always present between the tooth faces no matter how long the truck has been standing, provided, of course, that the case is originally filled as the makers direct and kept up to the mark afterwards.

Again, engineers are not divided evenly, as Mr Page thinks, on the position of the worm above or below. For heavy truck service they are unanimous in favor of the overhead system, as introduced by John Dennis in 1901. In light pleasure cars the overhead system decidedly preponderates, and in the other cases, I question if lubrication has had as much influence on the location as had low centre of gravity all around.

The use of worm gearing on trucks brings up some curious problems and only practical experience can determine their solution. Mr. Page should gain some of this experience under actual road conditions, and then make full use of his intelligence to deduce his theoretical basis on which to build his design.

Yours truly,
JOHN YOUNGER, B. S.
Mechanical Engineer, Commercial Vehicle Department of Pierce-Arrow Motor Car Company.
Buffalo, N. Y., Jan. 22.

IN THE MARKET FOR ONE OR TWO TRUCKS.

Editor MOTOR TRUCK:
Sir:

We would like to have it known among the manufacturers of commercial vehicles that we are figuring on the purchase of one or two motor trucks for delivering Portland cement and other materials. Nothing less than a three-ton truck would be of any service to us and we would probably prefer a five-ton truck, if it can be shown that maintenance costs are not excessive.

We wish information as to price, estimated cost of upkeep, and actual cost of upkeep, as shown by the experience of various users. The experience of building supply dealers is much more valuable to us than any other kind.

Yours very truly,
KOSMOS PORTLAND CEMENT CO., Inc.
Charles Horner, Vice President.

PROMPT SERVICE WITH MOTOR CARS.

Efficient service and promptness in the delivery of merchandise are features of the automobile appreciated by both the business man and the purchaser. There is, perhaps, no industry where promptness is more desirable at times than in the coal industry. Many times the fuel is delayed in reaching its destination when hauled by the horse drawn equipment, especially when the weather conditions are unfavorable for the animal.

The motor truck eliminates tardy deliveries, is not affected by heat or cold, and is cheaper a ton-mile than any other form of transportation. The practicability of the motor car was demonstrated in New York City recently when one of the large hotels sent in a hurry order to H. L. Herbert & Co., which concern maintains a fleet of Commer cars. Three machines were placed in service, hauling the fuel to the hotel on Sunday morning and at night 240 tons had been delivered. The three cars made 33 trips and one delivered 94.5 tons. These same vehicles, during the first 19 days of December, hauled 2700 tons, including short and long hauls and during a period of heavy snowfall when the concerns utilizing animals were unable to make deliveries on time.

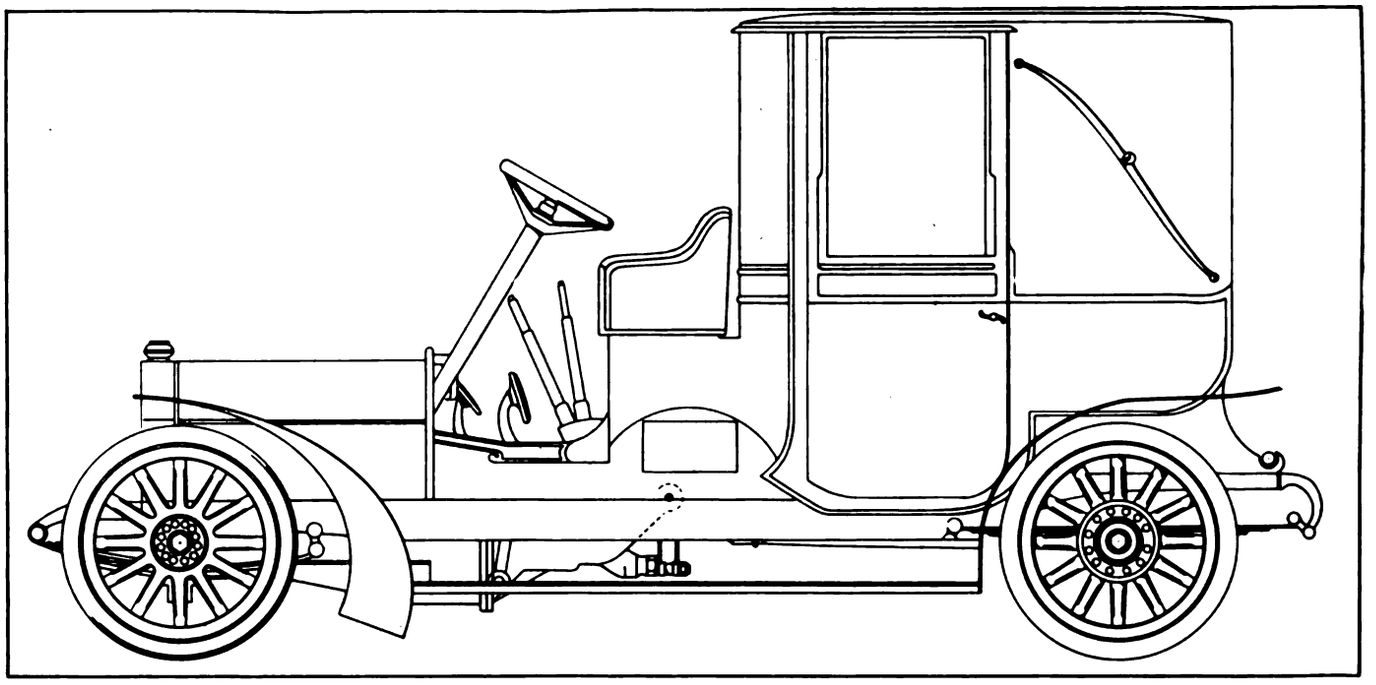
FOX PUBLIC SERVICE MOTOR CAB DESIGN.

Vehicle Having All Desirable Passenger Requirements, Adequate Power and Speed, Designed with Proven Mechanical Construction to Secure Extreme Economy of Operation, Maintenance and Upkeep—Simplicity and Accessibility the Features.



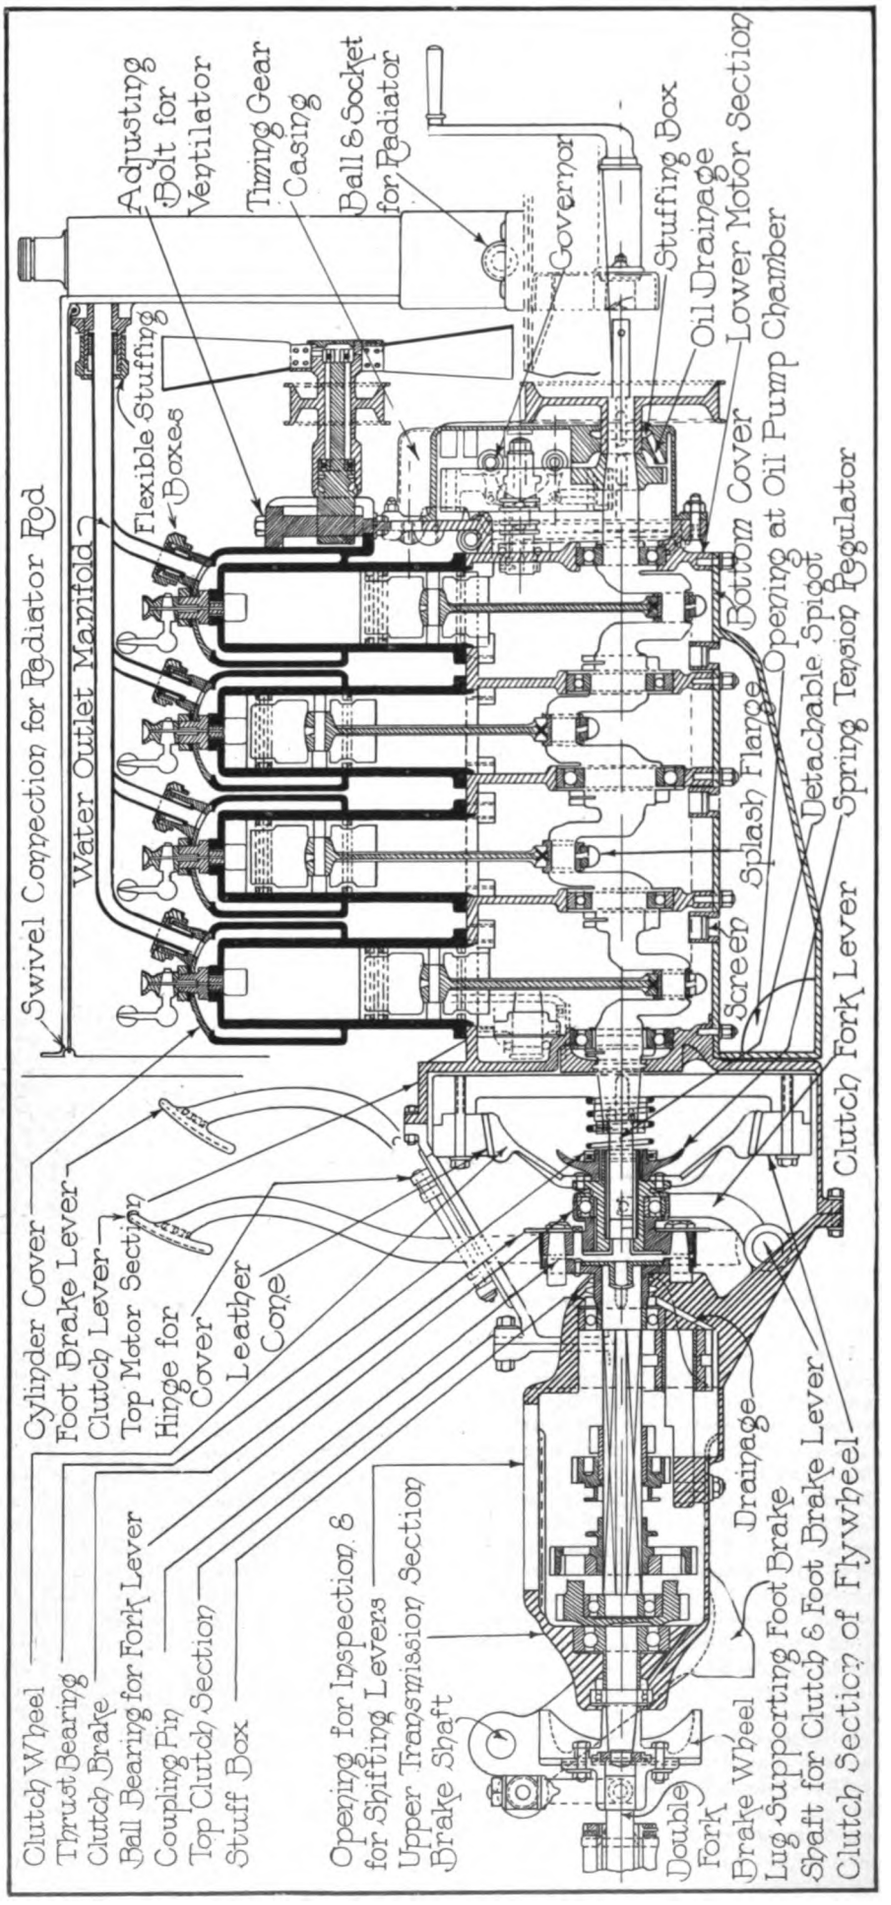
By Joseph P. Fox.

PUBLIC vehicle service the world over has been with reference to the demands of the people, whose needs may be more or less dependent upon conditions. The utilization of the motor conveyance has in many communities, especially in the larger cities, extended to such service, and companies operating in some instances hundreds of cabs are not unusual organizations. Such companies are organized for pecuniary profit and it is essential that they be profitable, as should be every business enterprise.

It is natural in engaging in any work that experience will develop needs and policies. In the transition from the animal to the motor vehicle it has been found in every instance that factors of large importance have been overlooked or underestimated. The essentials of business custom or methods have been seldom lost sight of, but ignorance of the use of motor cabs and the changed conditions resultant from extended radius of movement have wrought developments that must be accepted and must be dealt with.

It is impossible to deny facts and it is equally certain that the motor cab is the only vehicle that will meet the requirements of the people. The public must have a cab. This demand is imperative and is universal. The people cannot have a satisfactory public service provided by private corporations unless this can be conducted to a profit, and a profit that will equal what might be gained in other businesses. Neither can patronage be impelled unless the fare charges are reasonable.

This focuses attention to the cab itself. Undeniably the vehicles that have been in service have been more or less experimental in the sense that each design and construction had not the service to justify a conclusion that it met fully the demands of every interest. In fact, only after several years of use has it been possible to judge with fairness whether or not some machines have been desirable for such service. Again with the development of motor cars the people have demanded that such improvements be incorporated in public cabs, this entailing more or less costly changes for the operating companies. It has been experienced that the machine that might be satisfactory for use in one locality was wholly unsuited to another. Another fact emphasized by continued service was that it was necessary for the cabs to be operated as nearly continuously as possible, and that a heavier and more enduring construction than had been the vogue with pleasure machines was a vital need. In connection with this, simplified mechanical design, or minimizing the number of parts, especially those moving, was found absolutely necessary. Mechanism that would endure under excess work, that would not easily become deranged, that could be restored when necessary with the least loss of time and a minimum of expense and labor, that could be operated with economy in consumption of fuel, lubricant and tires, that would have sufficient power and speed, has been the goal sought by engineers.



The Fox Public Service Cab, Designed for Five Passengers, with Left Side Control on Long Wheelbase Chassis to Secure Riding Comfort and Lessen Mechanical Wear.

In considering public service it has been invariably the experience of the companies that have been profitable that the best equipment that could be purchased was the most economical in that it endured the longest, had appearance that attracted patronage, and met the requirements of the people. This means, of course, that urban conditions are to be dealt with. So far as the people are concerned there has been no change in the quality of service demanded with the transition to the power cab. In fact, the cabs that make the best impression in finish, that have the power and speed, that are the least noisy, are patronized to the rejection of those which have not all or the most of these qualities.

After extended study of the subject during a long engineering experience abroad, where power cabs have been in use for fully a decade, and careful observation of the conditions generally obtaining in this country for a continued period, the writer has become convinced that the

Digitized by Google

requirements of public service differ but slightly, while the needs so far as the vehicle itself is concerned are practically the same. Neither is there a material difference so far as the cost of the machine enters into the proposition. While it is true there may be variance in differing items of operating expense it is also a fact that when these are collectively regarded, or even separately compared, it will be found results are surprisingly similar.

I am firmly convinced that the public automobile cab must be at parity with the horse equipment of the large and successful service companies. It must have every quality to impel patronage and to be profitable as an investment. Such a vehicle cannot be low in price or mediocre in design. It must be uniform in every essential detail and it must be harmonious with conventionalities as viewed by the motorist, by the individual who regards appearance and by the person who has merely practical requirements. It must be economical of operation from every aspect, for only by its aggregate economies will it be profitable. This means economy of time through certain and continued speed, through continued service, through immunity against derangement or failure, through accessibility of mechanism when repair or restoration is needed, through ease of adjustment for wear, through interchangeability of components, through the use of the highest quality of material; economy of operation through low fuel consumption, through minimized need of lubricants, through small tire wear per mile driven, through low cost of parts necessary for replacement in restoration, through elimination of the customary causes for wear, through positive lubrication, through minimized labor in ordinary care and attention, through utilization of a large part of the power developed, through certainty of control during every condition of service and through the great endurance of the entire construction.

In the matter of appearance it goes without saying that the vehicle will be desirably maintained so long as it is profitable and is utilized by the people. As a business proposition it must be kept to a standard, and when it has ceased to be desirable for passenger requirements it may be diverted to another form of service, for which it may have practical qualifications. It is not practical to make estimate of the cost of such a cab as I have outlined for so much depends upon the conditions for designing and experimentation, upon the expense for factory equipment, upon the character of workmen, upon the character and quality of the material, upon the quantities of material purchased, upon the assembling and inspection, and upon the cost of selling. It may be assumed that there will be wide difference in these items according to circumstances of production and where manufactured.

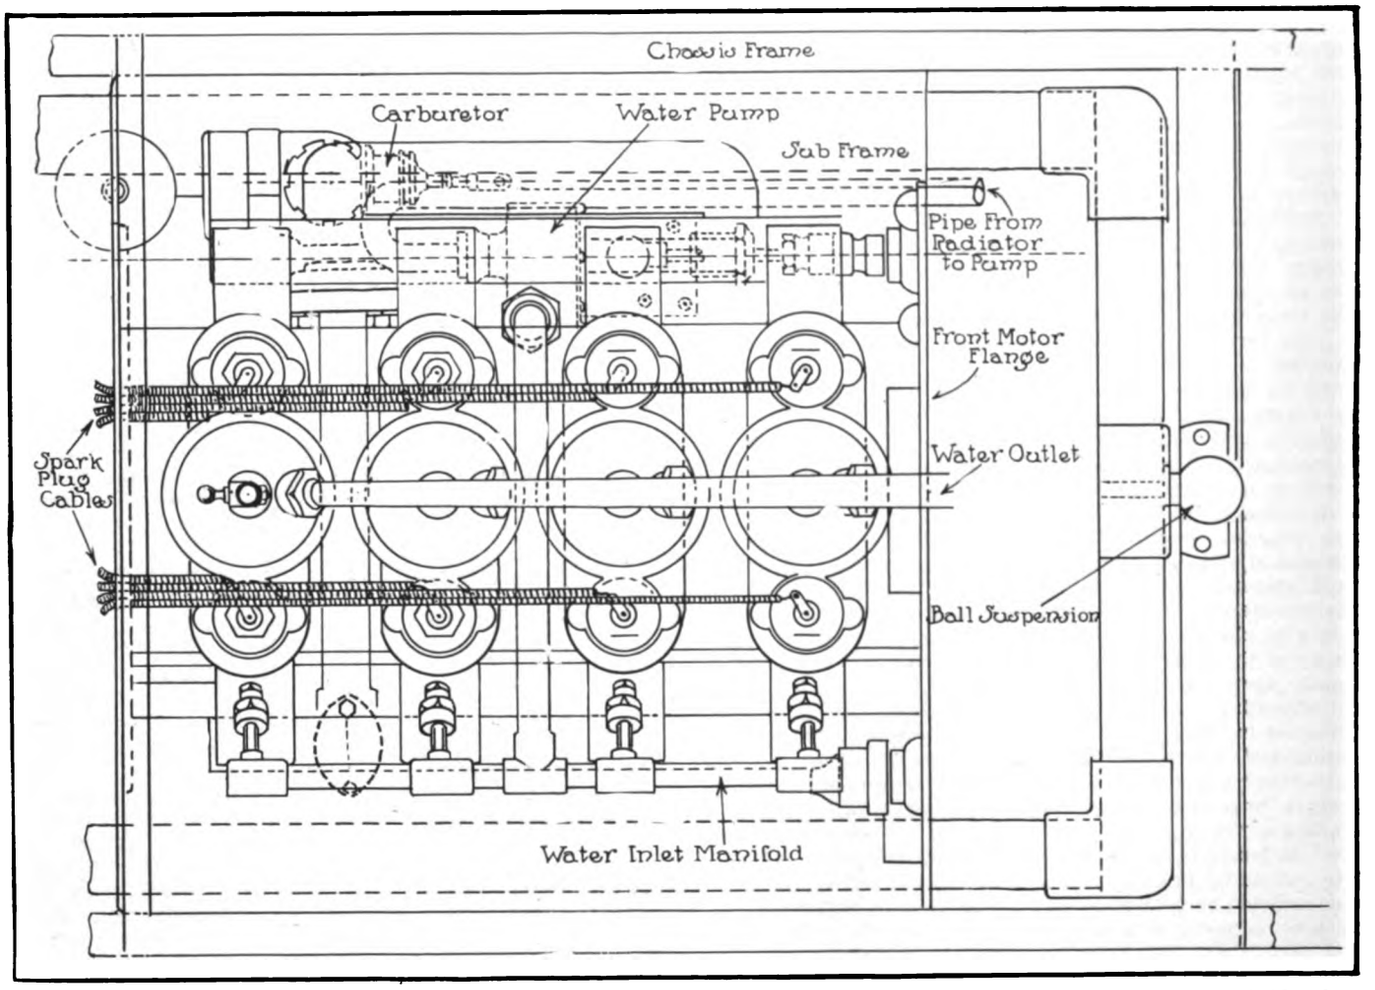
Having considered fully all these aspects and requirements I have designed a motor cab which will probably combine every practical quality that is necessary or desirable. It is not experimental in the application of any principle. Nothing is theoretical. Every construction has been demonstrated to be thoroughly mechanical and every detail has been adopted with a view of creating what will endure hard service and make for economy of operation. There is a wide margin for safety in every element. Despite this there is no excess weight that will entail increased tire wear. The purpose has been to have adequate power with a minimum of fuel consumption, to eliminate friction so far as possible, to use this power to the fullest advantage, to have a sufficient speed to afford a satisfactory service, and have the capacity for the extremely varied work required of a cab.

In this design the chassis and body equipment has been considered, but the chassis will be reviewed specifically and the body installation only insofar as it has been regarded in its relation to the proportioning of the chassis. But it is evident that the capacity of the cab and the work it has to do must influence every mechanical detail of the chassis to a certain extent. This cab has been designed to meet the requirements of the police regulations of Berlin, Germany, which compel that two passengers be seated comfortably on the rear seat of the enclosed body, that there be reserve or folding seats for two additional occupants of the body, and that there be ample room for the driver and a seat for a fifth passenger beside the driver, making in all six persons that the vehicle will carry without crowding. Another essential is that such cabs be turned in a 10 meter street (approximately 33 feet) without cramping or backing. This ease in turning is a quality much to be desired in narrow streets and in ordinary country roads. Aside from this it minimizes the element of danger from backing. The wheelbase is 2965 millimeters, or 116.759 inches, this being as long as this turning requirement will permit for the purpose of obtaining the additional ease in riding so essential for comfort and minimizing the stress of operation upon the mechanism of the vehicle.

The foreign service for motor cabs is exacting in that in many of the large cities it is not infrequent that they are hired for comparatively long journeys by tourists who do not have their own machines abroad with them. They are driven over good roads in many instances, but there are indifferent and poor highways in Europe, as there are in this country, and often these ways have gradients that are several miles in length on which the motor is required to do its hardest work. On such grades as these it is necessary that the brakes operate positively for the protection of the cab and its passengers and for those who are also using the highways.

In cities the proportion of good streets is generally larger than in this country, but in some sections the paving is ancient and driving upon it causes severe stresses when speed is attained. This condition parallels what may be found in the principal cities of America and it is a fact that adjacent to these communities the roads are by no means poor. Very often they are excellent and it is unusual to find the extreme grades to be met with in many European nations. In England, for instance, where the highways are regarded as being very good they are also narrow outside of the towns and cities, and they are quite as steep as they are in continental countries. The roads of France are not without the long grades despite the admirable character of the surfacing of the "routes nationales," and in some sections of Paris paving may be encountered that would almost cause an uprising did they exist in this country.

It will be seen that the use of the public cabs in Europe is quite often very similar to that for which touring cars are employed in America. Because of this it has been deemed desirable to make the wheelbase length equal to what may be considered satisfactory dimensions in the United States for pleasure vehicles. There is no question that this produces a better all-around machine even though there may be an advantage with a shorter wheelbase for use in extremely congested traffic. As a matter of fact it is entirely reasonable to believe that the requirements of the cab service in America will more and more parallel those of Europe, and this being so the longer wheelbase cab will be preferred because of the qualities referred to. It is the comment of those who have contrasted the types of long and short wheelbase cabs that there is decidedly more comfort with the former, to say nothing of the lessened wear of the mechanism. The same condition applies with other forms of motor vehicles similarly differing.



With any form of motor vehicle the power plant and driving mechanism is the most costly and deteriorates with use proportionate to the care given. The term used covers the motor, clutch, transmission or gearset, driving shaft and rear axle. These must be designed with reference to the service, and the one must bear a harmonious relation to the other. It is not practical to expect a combination that will be in every way satisfactory unless every element is created to meet a positive need or condition, because no weakness ought to exist or develop when it is possible to insure against it. It is almost needless to point out that it is only through analysis of every detail and the most careful consideration of every possibility that the best results can be obtained. This does not mean the use of an inferior or less enduring material because of the first saving in cost. Neither does it mean the elimination of a part or a fitting that will serve an essential purpose because of construction economy, nor inferior workmanship when exacting work

Digitized by Google

means slightly increased expense. It has been stated by those who comment from experience that initial expenditure for a cab is not the main consideration with the purchaser, for the maintenance cost of the low price vehicle is certain to be relatively much in excess of the more expensive machine. This is not a reason for extravagance in any respect, but is the best argument why no desirable quality should be sacrificed or neglected in designing or constructing.

It has been stated that the elements of the car should be consistent, and this brings us to the most vital group, the engine, which should be no larger than is necessary to yield the service and yet adequate for all requirements. For obvious reasons the motor should be somewhat more productive than is really necessary under the best of conditions because of the fact that it should have sufficient reserve power for the worst. It must at all times do the required work well enough to satisfy the owners and users. It must be economical of fuel, especially in Europe, where gasoline costs approximately double what it does in America, and the operating expense is correspondingly increased. One of the most cogent reasons for the use of comparatively small cars in Europe is the excessive price for fuel as contrasted with its cost in this country.

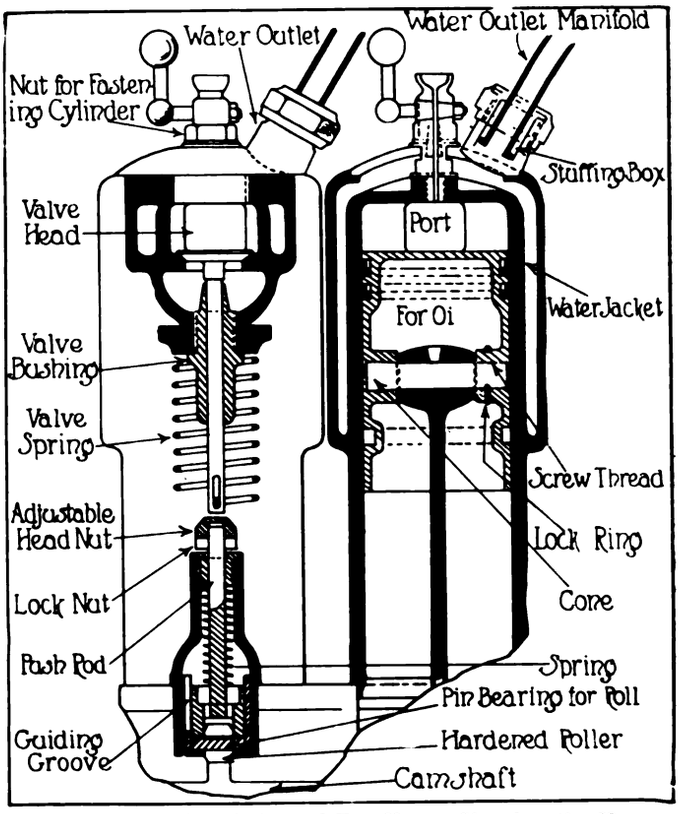
The motor from the aspect of fuel consumption must be as small and as powerful as is possible. When it is realized that the service of the cab may be from 12 to 20 hours daily and the mileage may be as high as 75, though the average may be from 60 in New York to 50 in Berlin and to 100 in London the full significance of the saving in gasoline is apparent. This brings us to the matter of cylinder dimensions, which proportions, when combined with engine speed, determine capacity. Considering every requirement of the cab I believe that a bore of 80 millimeters (3.149 inches) and stroke of 120 millimeters, (4.724 inches) affords the most practical machine for cab work in that it is sufficient for all normal requirements and, with a four-speed transmission, it will do every work that ought to be expected, not only of a cab but a touring car. This motor rates under the R. A. C. formula, which is known as the A. L. A. M. rating in America, 20.17 horsepower. Under the French and German horsepower ratings the horsepower is established at 24, which is approximately what it will develop at 1200 revolutions. At 1000 revolutions a minute this engine ought to drive the cab on a level at from 35 to 40 miles an hour. With a touring car equipment the chassis should attain a speed of about 50 miles on the same gear, which is the direct coupling. With the fourth or top gear ratio this speed ought to be considerably increased. These figures are stated to establish the capacity of this engine, which is of dimensions that have been amply proven in continued European practise. While the motor may appear small by horsepower rating this is not a sufficient basis for determination. Judgment should be upon what the engine will accomplish, and with the four-speed transmission it is possible to utilize the power to decided advantage and yet economize in fuel and lubricant.

Plan View of Fox Taxicab Motor Assembly, Showing the Water Inlet and Outlet Manifolds, the Arrangement of the Cables for the Double-Spark Ignition and the Ball Suspension for the Sub-Frame.

In other words, the engine has been designed with a view of having ample power for the service and yet it is to be economical from every point of view. The highest speed is within the 1000 feet of piston travel a minute that is regarded as the maximum for continued use, and the normal operation of the motor ought to be from 800 to 1200 revolutions. Within this range with the four speed changes every requirement should be met without overtaxing the engine. A near approach to ideal operation would be a comparatively slow speed motor giving any desired car speed on slight grades and over roads by the spark and gas, but still having a full reserve for starting and for heavy grades by a sufficient range of gears for the desired speed without racing the engine. Such conditions only make for economical and satisfactory service. With the use to be made of

Digitized by Google

the cab it is necessary that every factor that will make for endurance be utilized to the fullest extent and so far as possible the vehicle should be driven well within its capacity and never to its limitations. This fact has been regarded throughout the design and provision has been made to prevent what might be termed abuse or over-taxing the machine.



The choice of the motor dimensions and the character of the transmission are two decidedly important factors in cab design. To my mind on them depends very largely the success of the entire proposition. But no less important is the construction. For instance, the bushings should be as numerous as is consistent that the stresses upon the shafts be minimized and leverage pressure be eliminated or reduced to the lowest degree, so that both bearings and shafts will wear for a long period of continued use without noticeable deterioration. Every bearing must be of a standard type that they may be replaced at any time without special fitting. The ball bearings made by a well established firm would meet with all requirements, for such are usually standardized and a new bushing case will fit exactly in the seat of that replaced. In this design aside from the connecting rods there are no plain bearings used. All others are of the ball type and these may be removed and replaced by others without fitting. The wristpin and crankpin bushing are of a white bearing metal and are of liberal length as they take the blow of the explosions in the cylinders. It is to be noted that the use of such bearings minimizes the friction and allows the fullest delivery of useful power at the traction wheels.

In connection with the use of ball bearings it should be stated there are five main bearings for the crankshaft, each of them of large size and firmly seated in the webs of the engine case. With these there is no stress upon the crankshaft that is not well within its capacity for resistance. The camshafts are mounted in three large ball bearings. The shaft extensions that carry the timing gears are similarly mounted, and in the clutch, transmission, the driving shaft, rear axle, front wheels and in every part where such bearings can be installed they are used. This form of construction may be regarded as expensive, but this is one reason why the motor will do the work that has been stated, why the motor is economical of fuel, and why it will endure and is inexpensive of maintenance. The economy more than offsets the initial cost.

One of the most essential features of design is that the working mechanism of the car be encased for protection against dust, abrasive substances and destructive accumulations, a single housing containing practically all the moving parts of the engine, the flywheel, clutch and the transmission. This assembly is in every sense a unit. It is so constructed that it is in every way accessible and it is possible to remove it from the chassis by removing four bolts and hoisting it out. It can be taken from the chassis and another unit replaced and connected by two men in an hour and a half, perhaps in less time. It is entirely practicable for a spare power plant unit to be kept for emergencies and should it be necessary at any time to do so it may replace that in a chassis and the cab continued in use while work is progressing on the one removed.

The casing is one of the most important features of the design. It is sectional, of aluminum castings, and any one of these sections may be removed to examine or work on any part. To illustrate, the engine case or base proper consists of an upper section to which the cylinders are bolted, a bottom section and a base or bottom plate, the upper section carrying the front of the case proper. The bottom section forms the bottom of the housing for the flywheel and clutch. Back of these is the bottom section of the transmission case. Above the rear extension of the lower section is the top section of the flywheel and clutch housing and in this is an inspection plate or handhole. Back of this is the top half of the transmission case, in which is also an inspection plate. Bolted to the front of the engine case is a case or cover for the timing gears. The different compartments are entirely separate and apart from each other. The case, though in sections, is exceedingly strong and it is comparatively light and is stiffened by the transverse webs and flanges. All of the joints are lapped so there are no weaknesses in the design. The case is designed so that by the removal of a few bolts any moving part may be inspected, examined or worked on without dismantling the motor, which is an exceedingly important feature, and no adjustment need be disturbed.

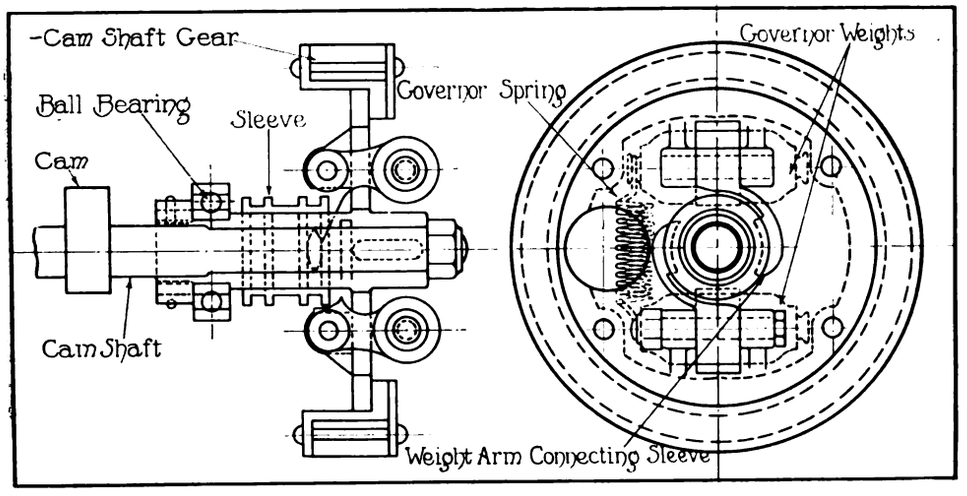
To illustrate possibilities, the timing gear casing may be taken off and the engine operated, showing the time gears in operation, the condition of all the forward bearings, and state of the engine governor. By removal of the bottom plate every main bearing can be examined, the condition of the camshaft bearings and the big end bearings of the connecting rods seen, and the pistons and connecting rods may be removed entirely and work performed upon them. In this manner, too, the cylinders may be cleaned of carbon from below in a manner quite as thorough as if they were removed from the case. By removing the caps from the big ends of the connecting rods, the rods and pistons may be dropped out and cleaned, the rings examined and the condition of the wristpins seen. The bases of the cylinders are machined to fit into the openings in the case and the fit is accurate, this affording a better anchorage, and the cylinder bore expands at an angle at the bottom for

Sectional View of Cylinders of Fox Motor, Showing the Manner of Holding the Water Jacket Caps, the Water Outlet Manifold Stuffing Boxes, the Low Wristpin, the Rings and Oil Chamber of the Piston, the Valve and the Valve Operating Mechanism.

a half inch, this permitting a piston and its rings to be pushed up into a cylinder without difficulty, the rings contracting to the cylinder diameter under comparatively slight pressure.

There is another even more convenient manner of performing such work which will be described in connection with the mounting of the motor.

The engine case is given a maximum strength with a minimum weight of metal by the bridge design within the assembly. It is protected against stresses by its suspension in the sub-frame. It cannot be twisted or distorted or the shafts sprung or misaligned through any legitimate use, and nothing short of complete wrecking of the vehicle would materially affect the mechanism.



The cylinders selected for the motor are cast singly, this form of construction being chosen for a number of reasons, all of which are valid. These might be summarized thus: The single-cylinder unit is first of all the cheapest from a manufacturing point of view, this meaning the least cost, but it is also possible to secure uniformity of wall thick-

Digitized by Google

ness (an essential for efficient operation), to have the water jackets completely encircle the cylinders, to thoroughly clear the water spaces of core, to later on clean them of scale and deposits that might reduce radiation, to economize in machining and finishing, and to minimize expense if it is necessary to replace a cylinder. The cylinders are cast with a wide opening at the centre of the head which is covered with a plate secured by a nut through which the shank of the compression relief cock passes to anchorage in the inner cylinder head wall. This opening makes possible removal of core and deposits and examination of and repair of the cylinders under certain conditions that would mean replacement with any other design. Where a damaged cylinder is by no means a remote possibility the dual cylinder unit or the en bloc design would mean a decidedly larger expense for replacement. With the water jacket completely about the cylinder the cooling is made more effective, a very potent element in continued service of a car.

The head is of the T form with the intake at the left side and the exhaust at the right. The design is the most practical for any cab in that it permits the use of a double set of spark plugs for ignition, each plug being located in the head of the valve pocket directly above the valve. The two plugs are fired simultaneously in each cylinder, this insuring a much more rapid combustion of the gas and naturally a greater expansive force from the explosion of the charge. This form of ignition does not require so great advance of the spark and consequently there is lessened resistance against the compression stroke, and with the firing when the piston is nearest top centre greater power is developed. With this design it is possible to use a thinner and more rapid burning mixture, to economize in fuel and lubricant, and to produce results that have been established as practical in every way. It will not be disputed that each charge of gas of stated proportions has a definite heat or power value and the utilization of this power depends upon the design of the motor. It can be stated that much of the heat value of the mixture is lost through incomplete combustion and where combustion can be improved it is obvious there is a saving. Theoretically the time to fully energize the power stroke is when the piston is exactly at top centre and ready for the downward movement. Any power exerted upon the piston before exact top centre must be overcome by the power stored in the flywheel momentum and is manifestly lost, while if not exerted at top centre the expansive force is reduced in proportion to increase of combustion space by the downward piston movement over the combustion head area. The maximum of power development is nearest realized by the use of the double ignition system.

As an illustration of the strength of this claim and as an example of how important is the ignition system of motors for power vehicles it is significant that in practical tests the double spark system has been proven to develop 16 per cent. more horsepower from the same motor than was realized by the single spark system. The tests to which reference has been made were in January of last year before the Society of Automobile Engineers on the dynamometer of the Automobile Club of America. The engine with the single spark ignition reached 24 horsepower at 1750 revolutions, which was the maximum obtained, there being a reduction in power delivery above that of speed. With double ignition and no more change than simply adding the second set of spark plugs to the engine it was found that it delivered 24 horsepower at 1500 revolutions, under exactly the same conditions. The power was increased to 28 horsepower at 1950 revolutions. The extreme gain absolutely established was approximately 16 per cent. It will be seen that this means practically a gain of one horsepower for every six, or taking the motor under its A. L. A. M. rating (20.17) with this form of ignition on the basis of the tests it ought to develop 23.39, a very material increase of power. This additional power is a substantial reason why this form of ignition has been adopted for this cab motor, especially as there is no increased consumption of fuel. As the ignition means simply one more set of wires from the magneto and one more set of spark plugs it will be seen that there are no complications. Besides all this there is the added protection from failure of a spark plug, the breaking of a secondary wire, or any other probable defect that might seriously impair the efficiency of the engine. The ignition current is supplied by a Bosch magneto designed for the double spark system, this being a true high-tension instrument.

Governor of the Fox Cab Motor, Which Is Contained Within the Camshaft Gear and Operates a Sleeve Sliding on the Shaft, Controlling the Supply of Fuel to the Motor.

The form of the cylinder with its relation to water jacketing and radiation has been briefly mentioned. The water jackets are large and the water is circulated through a flanged tube radiator by a positive pump. This type of cooler is advised as it is not susceptible to serious damage should it be frozen and it may be easily repaired should it be so damaged. The water passages are large and the water is circulated freely. There is less possibility of organic deposits accumulating in the bottom of the radiator from the heating of the water. The water is forced from the radiator by the pump to a manifold extending along the cylinder heads and connecting with the water jackets directly above the exhaust valves. The water is injected across the jacket of the exhaust valves at an angle that directs the flow to the bottom of the water jacket at the opposite side of the cylinder where it is turned to either side and after circulating about the base of the jacket it flows upward to the upper portion of the chamber and is forced out to the radiator through a manifold with connections with easy curves to insure a free movement of the water.

The plates covering the openings in the cylinder heads carry the connections for the water outlet manifold and the connection is made by the manifold tubing set into stuffing boxes, this giving a water tight but flexible joint. The radiator end of this manifold is similarly connected with the radiator and there is similar flexibility of this joint. This eliminates all rubber tubing with the sources of trouble from deterioration, the circulation of the water is positive and certain, while the water piping can be disconnected with the greatest ease. Any possible movement of the motor assembly is provided for and the water circulation will not be impaired. There is none of the customary annoyances of the other forms of connection.

The motor is lubricated by a combination of the force feed by a gear driven pump and splash. The bottom of the crankcase is divided by the webs into four compartments and below the base of the rear compartment, formed in the housing is the reservoir for the oil. There are drainage holes in the webs and in the division so the oil always fills the reservoir and is maintained at a predetermined

Digitized by Google

level in the compartments when the engine is at rest. Driven by the inlet camshaft at the rear of the motor is the pump which is installed in the reservoir and can be reached from the outside of the engine case. This pump draws the oil from the reservoir and forces it through large tubing to points above the main bearings whence it flows over the bearings and into the compartments into which the crankpins and big ends of the connecting rods sweep. The oil is also forced through the forward main bearing into the timing gearcase and thence is distributed by splash over the timing gears. Stuffing boxes prevent the oil working out of the timing gearcase around the main shaft end and at the rear of the engine case, these being provided with drainage into the forward and rear compartments so that any excess lubricant is siphoned from the stuffing boxes. The caps and bearings of the connecting rod big ends are drilled for a free circulation of oil about the crankpins. As will be obvious the oil accumulates in the channels of the ball bearings and there is always a sufficient volume of oil in these bearings.

The lower ends of the pistons when at the lowest point in the cylinders are below the base of the cylinders. The wristpins are set a little above the exact centre of the pistons to remove the wristpin bearing as far from the head as is possible, where the heat is not as intense and the wristpin lubrication will be the most effective. This minimizes the side thrust of the piston on the cylinder walls as well. The pistons carry six rings, four above and two below the wristpin bearings, and between the ring groups the piston is machined slightly smaller, this space filling and carrying a volume of oil when the engine is in motion that constantly lubricates the walls of both cylinders and pistons. The six rings insure a higher compression in the expansion chamber and steady the piston in its movement, there being no possibility of violent contact of the piston against the cylinder wall under any condition of operation.

The valve action is unconventional in that there is a spring fitting that constantly maintains the pushrods in contact with the cams, minimizing noise and insuring against undue wear. The cams are retained on the camshafts by collars. The pushrod guides are screwed into the engine case and are retained firmly by keys. In these guides are the pushrods which are hollow sleeves in the lower ends of which are hardened steel rollers or wheels. The roller shafts mesh into slots in the lower section of the guides, which prevent turning. On top of the guides are caps through which the pushrods rise and fall and at the head of the pushrods are adjusting nuts by which the clearance is established. The valves are of nickel steel and the stems of the same material. The pushrods carry collars and between these collars and the cap of the guides, surrounding the rods, are spiral springs which force the rods downward with the release of the cams. The action of the pushrods is positive and there is always abundant lubrication.

Back of the engine case is the case containing the flywheel and clutch assembly. There is a recess in the rear web of the case into which the rear main bearing is seated, and against this is a large recessed collar that contains the rear stuffing box. The clutch is of the cone type with the spring retained between the web of the flywheel and the clutch member, the flywheel face being divided for the insertion of the clutching member. This member is screwed on to the end of the coupling shaft and locked firmly. The clutch is so designed that by unscrewing the coupling shaft and two retaining bolts of the flywheel the clutching member may be removed from the case after the removal of the upper half of the clutch casing. The removal can be performed in an extremely short time without in any way disturbing any other of the mechanism. This clutch assembly has a ball thrust bearing to sustain the clutch spring pressure and another ball bearing to minimize friction between the axle and the fork lever by which the clutch is actuated. The crankshaft extension is removable by means of a special wrench which fixes the clutching member so that the flywheel may be turned. It will be noted that the connecting movement of the clutch when engaging is backward from the motor against the angle of the inside of the flywheel. One of the advantages of this design is that of modifying the oscillatory movement of the motor shaft and causing a softer motion of the transmission during the period of clutching. This is accomplished through the action of the lever and the expansion of the clutch spring. This oscillatory movement of a shaft is noticeable with a dynamo or electric motor and as a gasoline engine is driven by a comparatively irregular force this vibration of the shaft is pronounced. This clutch is so effective that a properly designed and assembled car may be started by it on any of the different speed gears and on any grade as softly and flexibly as can be a steam or electric vehicle. It is apparent that this manner of clutching materially reduces the wear upon any of the transmission members as well as making for the increased comfort of the passengers. The clutch and flywheel are contained in a housing that is oil and dust proof and there should be none of the causes of trouble that may be met with in other forms of construction. There can be no question as to the accessibility of the design.

The four-speed transmission has the highly important feature that it is possible to change from one speed gear to the other without passing through the gears between the two ratios. There is also the simplicity of movement of the shifting lever. There is an automatic brake attached to the clutch to prevent spinning in gear changing, which minimizes the wear upon the gears when changing speeds. By an automatic lock the gears are prevented changing while the clutch is engaged. On the extension of the transmission shaft is the service brake, which is operated by a foot pedal.

The control levers are in the centre of the chassis at the right of the driver, and these are mounted on the transmission assembly, there being no connection with the chassis frame side member, as is the customary form of design. This makes it possible to secure the true form of three point suspension that has been given this assembly. The engine case is cast with a wide flange at either side that serves to carry it and the clutch and transmission perfectly anchored on the sub-frame, this flange forming a complete deck about the motor and protecting it against dust, water, mud or dirt that might be thrown from the surface of the road. No drip pan is necessary.

The sub-frame is of heavy tube and it follows the sides of the assembly from the front to the rear. The forward end of this frame is mounted on a ball joint carried on the forward member of the chassis frame and at the rear end of the frame is a sleeve through which is passed a tubular member, the ends of which are mounted in slides in the chassis frame.

(To Be Continued.)

GAINS CONTROL OF UNIVERSAL.

Announcement is made from Detroit that Howard Walton of New York City has acquired full control of the Universal Motor Truck Company of the former city, and that a new concern will be organized with plans for a general enlargement of the business. The Universal company was formed about a year ago with capital of $350,000. It is understood that Vincent Link, designer of the Universal truck, will remain with the new owner as chief engineer and designer.

SPECIAL SHOW FOR PITTSBURG.

Following out the plan adopted by the Pittsburg Automobile Dealers' Association last year, a special week will be devoted to commercial vehicles in its show at the Duquesne Garden, Feb. 5-10. Numerous new lines are being represented in this city this season, and it is anticipated that the showing will be larger than in 1911. It will be remembered that Pittsburg was the first city, outside of New York and Chicago, to hold a separate truck show.

"THE MOTOR VEHICLE FOR CITY AND STATE."

Discussion of Economies of Power Wagons for Urban and Interurban Transportation by Hayden Eames, General Manager of the Studebaker Corporation, Before the Boston Electric Vehicle Club.

THE subject of urban and interurban transportation by power wagon, with an attention to the utility of the electric type, was discussed at length by Hayden Eames, general manager of the Studebaker Corporation, at a banquet given by the Electric Vehicle Club of Boston to federal, state and municipal representatives located in Boston. The banquet, given at the City Club, was presided over by William H. Blood, Jr., president of the Electrical Vehicle Association of America as chairman, and LaRue Vredenburg as toastmaster. Mr. Eames' address was given as "The Motor Vehicle for City and State." He said in part:

It seems perfectly ridiculous at this late day to come here and undertake to tell this gathering much about the electric vehicle or any other form of motor vehicle. You will have noticed that I am supposed to speak here tonight of the motor vehicle in its application to the city and the state. Now it is just in such classification as this in which most of the mstakes on the subject of the motor vehicle have been made. Inefficient brevity versus undue qualification have obscured the main issue. There is the urban and the interurban service. You often hear the man on the street making an application of something to motor wagons when that belongs only to its application to city service or to interurban service. It is going to be difficult in this matter to make a compromise between ineffective brevity and undue qualification. Hardly any statement you can make regarding the motor vehicle is unqualifiedly or strictly true, and so I shall have to ask you to take it on faith.

Dinner by Electric Vehicle Club to Federal, State and Municipal Representatives Stationed in Boston, at the City Club's Banquet Hall.

One of the reasons Europe has helped us so much less in power wagons than in the matter of pleasure vehicles lies in the fact that recent interest in Europe has centred upon interurban transportation. The character of their roads and their high freight rate contribute a great deal to that. As long ago as 1903 the records in their urban transportation in Europe had a high degree of specialization and thoroughness. Acording to a report in the Liverpool Post they were transporting in that city freight at the rate of one and a half pence a ton a mile, which was extremely good at that time. One example is the Manchester ship canal. You all know that American speculators pronounced it to be impracticable. The railway freights were so high on account of short haul and frequent handling. But today it is not an objectionable thing.

As a result of this method of transportation Europe is away ahead of us not only in transportation, but also in highway upkeep. They found that the automobile and the horse together had about the same effect on the highway as a pickaxe and an air blast. The horse did the pickaxing and the automobile did the air blasting. It was found that the roads gave way much more rapidly than before. I understand under the special management of Harold Parker that problem has been solved, but as to how far they have gone in Europe I do not know. The whole thing turns on meeting that particular condition. It does not apply much to city use. There does not seem to be much doubt—and it is growing now in a more or less tentative manner in the West —that transportation from rail heads and way stations by automobiles is going to open up new territory. Possibilities in that direction are being recognized in Europe, and were recognized a good while ago. In 1898 the underwriters of the Belgium railway system found that by the migration of operatives from the Namur district to the Baltic provinces of Russia, the underwriting had become unprofitable. They ransacked the world to find out how they could put automobiles into that territory.

One of the things which the British have had to encounter, and which this government has had to encounter in its interurban transportaion was the strength of bridges. In England they dodged that issue by adding the seven-ton lorry and the three-ton truck. In that way they got rid of individual units below that for which the bridge was constructed. The span style of bridges was found to be the best, and for military purposes this style of bridge is very good. For military use the weight of the gun limber is about 7000 pounds, and that is the limit as given by the engineer corps. Strange to say, this country is rather ahead of Europe in military experiments in the direction of automobiles for military purposes. In Europe the French and

Digitized by Google

German authorities have come out directly, saying that they have no hope of using automobile company wagons or any wagons with the troops. They limit the utility of power wagons to transportation and rail head camps. One trouble of the power wagon is that as a rule it is not designed for the special work of burden it has to carry. In this country, beginning next month, and for the first time in the history of this country will be made the first experiments in automobile company wagons. That is quite a departure, and is being watched with a good deal of attention. It is the first time that any military company wagons designed for the purpose will be used, but they have not gone so far as to experiment with electricity. These wagons will be run from Indianapolis to the South.

Now in such a comprehensive subject as this I have to speak carefully. I want to differentiate the urban from the interurban conditions, and to deal with the economic conditions as well as with the effect of freight rates. You can easily see without much discussion what that would be. It is a question of having a haul short enough so that the railway does not get the advantage of infrequent handling—longer than the horse could possibly be considered for. But it is all secondary. One of the differences between the European truck and ours is that of the design of the wagon. I do not hesitate to say that there is not any power wagon today that is designed with distinct reference to economic use, for instance. The ordinary design, such as the electric company makes, comes nearest, but the gas wagons do not come near the urban requirements.

You will get the idea when I call your attention to the difficulty of the detachment of units and the matter of mechanism. A five-ton truck costs about $4000 to the purchaser. He has to have spare trucks. The average number of spares in London was 30 out of every 100, and those 30 were under repair all of the time. They looked like lumps of sugar with flies on them. The floor of the machine shop looked like a gigantic watchmaker's bench. The secret is to have the units detachable, as is done in the electric vehicles, and that makes one of the cogent reasons for its superiority. Those things are not developed in Europe, partly because of the interurban service and partly on account of the maintenance charges. That difference in wages is also a fact.

But it is the urban delivery that really interests us. There are very few parts of the world where the roads are good enough to make interurban service of sufficient interest. What is very true about interurban service is frequently untrue about urban service. There is a great deal more information about the economies of urban transportation than most people believe. A man will say, "Yes, I know how that takes place," but in many cases you have to say, "No, it doesn't take place." And that seems to settle itself. The actual cost of an installation today can be reckoned without trouble, for there are ample data, and where these estimates have been made synthetically and tried out afterwards they have absolutely justified themselves, and that so-called question is a foolish question.

The day has gone by when the old-time idea of a "practical man" was a matter of admiration. That is, I mean of a practical man who has no other knowledge than that which has gone into his own life. You have to apply other people's knowledge as well as your own, and if you adopt that principle I unhesitatingly say that certain estimates I am going to read to you are as absolutely certain as if they had been actually done. There is not a single item among them that has had to be cast out in the slightest degree. The majority of articles received from time to time in the magazines and technical papers are written by people who have just waked up. They do not know more than the first notion about this thing, what information there is about it, and how other people have studied it.

Business men have not awakened to the possibilities of the electric vehicle. They have not watched its progress, nor do they realize how economical it is. The best proof of this was contained in a remark which was addressed to me today by a business friend who stopped me on the street and asked me what I was going to do in the evening. I said I was going out to dinner. "Can't you shake it?" he asked. "No," I said, "I have an address to deliver." "What is it about?" he asked. "It is on motor vehicles and the methods of transportation." "Well," said my friend as he grew enthusiastic over the electric commercial vehicle, "the power wagon is going to come." Now these people who say that it is going to come overlook the fact that it has been coming for 15 years past, that it is now here and has been here. Yet my friend had only just begun to realize it. The horse has been at a distinct disadvantage for 10 years past.

In 1901 and 1902 electric trucks were being produced and were transporting freight more economically—considerably more economically—than horses. The first automobiles developed as steam vehicles were followed in this country by the electric. Then the electric versus gasoline question began to occupy everyone's mind. There is not much of that now. It boils itself down to a question of mechanism and of drivers' wages. There isn't a doubt that the maintenance of the electric is much less than that of the gas driven car, and the electric has a tremendous advantage in the larger stations. The storage battery is improved greatly, but it was better than the horse then.

I remember that one great express company put in a lot of batteries and they were continually fooling themselves. The president of one big express company was stampeded by the taunts into putting in some electric vehicles in undue haste. They were shipped to a northern city. The batteries went out with no hold down and the freight was shipped to this station the same time as the vehicles. The drivers took the vehicles off the freight cars and then run them through the streets until the batteries ran out and then the drivers walked in. Those batteries gave out soon, and then came a man to replace the batteries. They had 12 wagons.

After this account had been cleared I walked into the man's office, and the mere sight of me almost drove him into a fit. He seemed to think I was to blame. At the end of the year I stopped there again and asked him how the installation was getting on. He said, "I hate to say so, but it has cost us less than we had set aside for the horses." He was deceived by that one experience, but they had to put in an installation, and that installation, when I inspected it was one of the best I know. There is the differentiation between the obvious and the real.

The electric vehicle has a tremendous advantage in large cities, as it moves quietly and is able to get to a designated point in a certain time—much less time in fact than a horse could cover the same distance. Picture to yourselves a London omnibus outfit and what gasoline vehicles require. With a gasoline station, no matter how serviceable or how good your equipment is, you have got to have a repair shop, and there must be a lot of mechanics in it. Now in an electric installation with 12 vehicles in it there never was a time when I saw more than three men there, and at no time out of the 20 occasions on which I visited it, did I see more than one wagon out of commission.

There is not the least doubt that the maintenance of electric vehicles is very much less than that of the gasoline vehicle. You can get more speed out of the gasoline, but for truck purposes this is not an advantage in the most congested parts of our city and under other conditions. I doubt if the streets will ever be clear enough to permit it. There has been a great improvement in the traffic of streets. The limits imposed by the present construction of streets might seem to be limits from intersections, and I don't see how that interference is going to be such as to deprive the electric vehicle of its advantage in the matter of maintenance.

Comparisons are misleading on account of misrating. Nearly all electric vehicles have been rated on the basis, roughly speaking, of the life of the wagon. The life of the wagon will be computed at twice the weight of the load. That will develop the result for horse wagons. They are getting closer and closer together, but many comparisons made on that basis are erroneous.

There is one point very frequently overlooked in power wagons. Not only will speed save travel, but increase in size will save travel. Time conditions are limited by overexisting conditions. But that problem is in a fair way of solution. It would not surprise me within the next 18

Digitized by Google

months to see electric trucks as high as 10 tons travelling eight or 10 miles an hour. In view of this, street conditions will have to be considered to meet this. These trucks will be bought irrespective of any notions people may now have about them. A great many people will be getting themselves on this subject in the very opposite direction from what they are today. They will be buying blindfolded as it were, and the people concerned in municipal affairs and in the condition of the street would better look those conditions in the face.

One of the difficulties in the introduction of trucks has been that very fact of the relation between the speeds of trucks and their weight and size. I remember an argument we once had with a western man. We succeeded after a laborious discussion, and by the application of a little ordinary commonsense in convincing him. It took us nearly two months to convince this western man that he wanted a wagon twice as large.

Of course most of this is very general. Some of the facts I am going to give you have been taken from reports which you doubtless have read. Up to Sept. 1, 1911, $10,000,000 worth of electrical trucks were purchased in this country. There are said to be 1000 gasoline trucks, registration trucks, in New York. Two and a half million dollars' worth were bought last year up to Sept. 1. We figure that it will take about 76,500 kilowatts to deliver the retail freight annually taken off the railways of this city, let alone other freight. About 3,000,000 power wagons will be required for this country. About 16 times as much freight is handled on wagons in this country as on railways, and that includes rehandling.

There is a great deal of hallucination abroad on the subject of the low efficiency of the electric vehicle. The low deficiency runs from 39 to 73, and the electric vehicles run about 80 per cent. There is nothing in all this talk about the heaviness of the electric vehicle. The electric vehicle is no heavier for the service it is called upon to perform than is the gasoline vehicle.

I have here some particulars of installations that have been worked out synthetically. Some of these are actually in use, and some are not. One large horse and wagon installation by a large packing company cost about $194,000, and the cost of the electric machines was $166,000. The horse expense amounted to $136,600 and the machine expense was only $113,000, including depreciation and interest on investment, and it showed an annual saving of $23,600. Another similar packing house more favorably situated showed a saving of $15,000 a year. Such results as these are all built up synthetically, and the allowances for battery maintenance are all excessive. This has been confirmed not only by actual application in some of these cases, but by actual application elsewhere.

One of the most profitable installations I know of is that of A. I. Piercy in New York. The manufacturer who sold him vehicles made a contract with him by which a certain fixed charge was to be made provided the manufacturer had power to select the station superintendent. Mr. Piercy could not appoint the superintendent without the consent of the manufacturer. Mr. Piercy was to pay the manufacturer back one-half of that figure manufactured in excess over that figure. Ten months ago they had been going 2.5 years, and at no time had any vehicle exceeded one-half the estimate upon which the installation was based.

Anybody hearing that kind of a story would immediately ask why electric vehicles were not introduced a long time ago. What was the trouble? The trouble was the same as in the case of every invention ever introduced anywhere in the world. Mr. Blood, at the meeting in New York on Oct. 10 said it was inertia, and that is about as good a word for it as any other. It is perfectly astonishing to see how the human mind works on this question. It has a sort of positive kind of inertia.

I remember the first electric vehicle with which I was concerned. A local carriage maker put up the body of it. When it came to the work it had a whip socket on the dasher. "What is the whip socket doing here?" I asked. "Why, we have always put them on," was the reply. How perfectly foolish it sounds.

Suppose a man came into your office with an invention, saying: "I have the most wonderful motor you ever saw. It has no handles, no steering gear. All you have to do is to speak to it and it goes or stops." You would say that was wonderful. The man adds: "To be sure, it goes sidewise when you don't expect, and it turns around sharp, stops without notice and changes its speed." You would say: "Good bye. I don't want anything to do with that invention." That is what the horse does.

Here is another hallucination. There is a good deal of mathematics about this: One of the commonest things you get from the habitual horse user is the statement that one-third or one-half of your time is standing still, and you have to save all your time on the other half. The whole situation is speeded up to some extent, and the ideal time comes into the power wagon more than it does into the horse wagon. You make allowance for the poor beast to get there, but you have to allow for his average condition. You speed the whole thing up to meet that condition. As soon as you introduce the power wagon you put that all out. In the case of a New York express company, when it ran horse vehicles they stood idle 35 per cent. of the time; when they used power wagons they stood idle only 22 per cent. of the time. You have got to use the new tool. It has been the whip socket and the sharp shoeing business that has prevented people from taking advantage of that splendid economy.

I remember the case of a man in St. Louis who delivered packages from a dry goods store. He never sorted the packages until after they had been put into the wagon, and he took advantage of the idleness of the horse to take the packages out and then sort them on the curb. When that dry goods store put power wagons in it was another thing. Then he awoke to the new facilities. All of you must be familiar with that attitude.

I might mention here the municipal ordinances that make the taxicab in this country impossible. People amusedly try to explain why they don't pay. The real explanation lies in the fact of the non-paying mileage which in London is 12.5 per cent. of the total mileage. The non-paying mileage in Philadelphia and New York is 55 per cent., and the reason is that the particular form of ordinance in relation to the arrangement of cab stands is such as to enforce that dead mileage. That is simply another example of the whip socket. You remember that a year or so ago there was a great deal of agitation regarding what the automobile was doing and how it was ruining the finances of this country. We all know what nonsense that was.

THE MOTOR CAR INDUSTRY.

The December issue of "The Gramm," a monthly publication devoted to the interests of the Gramm Motor Truck Company, Lima, O., contains an interesting article by B. A. Gramm entitled "The Motor Car Industry." It presents pertinent facts relative to the commercial vehicle and gives some idea of the numerous machines in service as well as the large number of horse drawn vehicles replaced. The company also issued a special number devoted to its Canadian interests.

LUMBER MEN TO BUILD TRUCKS.

Eddy Bros., a millionaire lumber concern in Bay City, Mich., is said to have become interested in the purchase of the Owosso Motor Company, Owosso, Mich., and it is understood that if the plan materializes the business will be removed to Bay City, where ample capital will be forthcoming to produce light delivery wagons in large numbers during the coming season.

KANSAS CITY'S SHOW PLANS.

Kansas City is in the centre of a section in which it claims there are more cars sold annually than in any other locality in the United States. Inasmuch as the two dealers' associations have been amalgamated this year, it is anticipated that the display of Feb. 12-19 will be of large importance in the industry. Special provision has been made for the showing of commercial vehicles.

BRIEF NEWS OF MANUFACTURER AND THE TRADE

The B. F. Board Motor Truck Corporation, Alexandria, Va., has created a preferred stock of $25,000.

The White Company, Cleveland, O., announces that James A. Harris, Jr., of the sales department, has been appointed advertising manager.

The J. I. Case Threshing Machine Company of Racine, Wis., has opened a New York City branch at 1860 Broadway. O. A. Lewellen is in charge.

The American Elastic Wheel Company, New York City, has been incorporated for $50,000. The incorporators include C. Feroci, F. Corsi and F. P. Ward.

The Moran Auto Sales Company, Grand Rapids, Mich., has been appointed agent for the Velie commercial vehicles by the Chicago branch of the Velie Motor Vehicle Company, Moline, Ill.

The Hartford Suspension Company, Jersey City, N. J., has opened a factory branch at 1524 Grand avenue, Kansas City. Henry Roemer is manager.

The Leighton & Hancock Motor Truck Company, 16 E. Walnut street, Columbus, O., has been appointed agent for the Sternberg commercial vehicles.

The Columbia Taxicab Company, Evansville, Ind., has been incorporated for $10,000. H. E. Hulseman, W. Wheeler and A. C. Mathias are named as directors.

The Nuse Wagon & Automobile Company has been incorporated at Newark, N. J., for $50,000. The incorporators were Fred Nuse, Louis Nuse and Fred Nuse, Jr.

The Automobile Horn & Pump Company of Boston was incorporated recently for $25,000. Anthony J. Son is president and Joseph Payne of Malden, Mass., treasurer.

The General Motors Truck Company, Detroit, has formed a service department in connection with the selling organization and this branch will be in charge of T. P. Myers.

The Penoa Motor Oil Company, Los Angeles, Cal., has been incorporated for $25,000. J. P. Smith, Joseph A. G. Brown and M. B. Armstrong are named as the incorporators.

The Automobile Omnibus Company of Lynn, Mass., was incorporated recently for $10,000. The incorporators include Eben R. Phillips, Patrice D. Theriault and James J. Liffin.

The Erwin M. Jennings Company, Bridgeport, Conn., has been appointed agent for the Alco trucks, made by the American Locomotive Company of New York City and Providence, R. I.

The Hydraulic Motor Vehicle Company, Milwaukee, Wis., was incorporated recently for $15,000. The incorporators include Calvin Stewart, August Baltzer, W. M. Stewart and W. E. Brown.

R. S. de Mitkiewics has resigned from the Motor Engineering & Sales Company of New York to accept a position in the truck department of the Peerless Motor Car Company of New York.

New Factory of the Federal Motor Truck Company at Detroit, Which Was Formerly Occupied by the Van Dyke Motor Car Company.

The Randolph Motor Truck Company of Delaware was incorporated recently for $200,000. The incorporators include H. O. Coughlan, Brooklyn, N. Y., and Welcome W. Bender, New York City.

The O. A. R. Motor Company of Plainfield, N. J., has been incorporated for $60,000 by A. A. Reed, E. J. Kuhne, H. G. Uhler, G. Reinberg and H. G. Uhler, Jr. The concern will manufacture motors.

The Powell Engine Corporation, 49 Lincoln place, Brooklyn, N. Y., will place a 1.5-ton truck upon the market shortly. It will be propelled by a four-cylinder unit power plant located under the driver's seat.

The Centaur Manufacturing Company, Buffalo, N. Y., was incorporated recently for $35,000 to manufacture motor car appliances. The incorporators include A. Schmidt, J. E. Barry and Bertha F. Schmidt

The Velie Boston Branch has reappointed Arthur G. Beharrell as agent for Lowell, Mass. The latter will maintain a service station, a feature of the policy of the Velie Motor Vehicle Company, Moline, Ill.

The Mercury Manufacturing Company, Chicago, received an order for 12 trucks recently from a laundry in that city which experimented with commercial vehicles of different types before placing the contract.

Digitized by Google

Welch & Suthergren, Worcester Mass., has opened a show and salesroom at 673 Main street and in addition to the pleasure car is handling the Peerless truck, made by the Peerless Motor Car Company of Cleveland, O.

The Rowe Motor Manufacturing Company has been incorporated for $500,000 at Camden, N. J. The incorporators consist of Charles D. Besore, Marion Lambert, Florence M. Caskill, all of 104 Market street, Camden.

The Firestone Tire & Rubber Company, Akron, O., has opened a factory branch at Dallas, Tex., at 1521 Commerce street. It is in charge of P. B. Talbot, who for many years represented the company as a travelling salesman.

The Findeisen & Kropf Manufacturing Company, Chicago, has made the following additions to its list of agencies: Ballou & Wright, 86 Sixth street, Portland, Ore.; Browne & Leacy, Real Estate Bank building, Savannah, Ga.; Joseph Woodwell Company, 201 Wood street, Pittsburg, Penn.

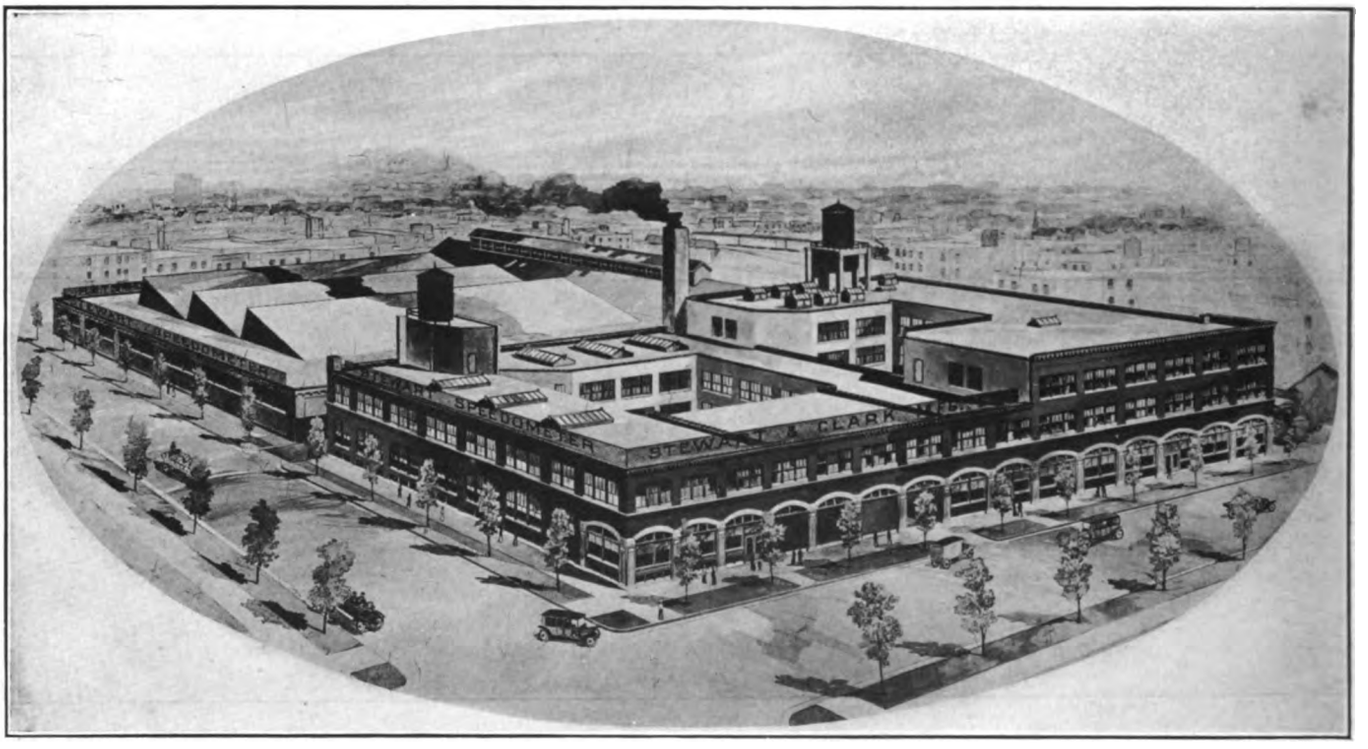
The Morse-Readio Auto Company, Springfield, Mass., which was incorporated recently, will erect a five-story brick and steel garage on Dwight and Chestnut streets and will maintain a service station for a line of G. M. C. trucks for which the company is agent.

The Lauth-Juergens Motor Car Company, Fremont, O., has completed plans for a new building 250 by 60 feet which is to be utilized for assembling and body building. Another large structure will be erected in the spring to take care of the increasing business.

The Kerosene Gas Producer Company, New York City, announces the opening of a sales office at 1926 Broadway of that city, where all communications in reference to the business of the Universal Oil Converter Company or the Kerosene Gas Producer Company should be sent.

The Swanson Motor Company, 5719 Wentworth avenue, Chicago, announces that in addition to several lines of commercial vehicles it is specializing in heavy trucks, having received a large number of orders for this type of power wagon.

James F. Evans has been appointed advertising manager of the Lozier Motor Company of Detroit to succeed C. A. Emise, who has been promoted to the position of sales manager. Mr. Evans is well and favorably known to the automobile industry, and was educated in Oberlin College and the University of Chicago.



The American Locomotive Company, New York City and Providence, R. I., announces that J. F. Gfrorer has been placed in charge of its service department. He has been associated with the motor car industry since 1903, during which time he has filled many important positions with several well known companies.

The International Motor Truck Company, New York City, has removed its offices and salesrooms from 30 Church street to Broadway and 57th street, where four floors of the Demarest building will be utilized. Robert Fulton and H. D. Watson of the sales organization of the company will establish quarters at the new location.

The Remy Electric Company, Anderson, Ind., well known maker of lighting and ignition specialties, announces the addition of a new service station and supply house at Dallas, Tex. It will be in charge of M. A. Price, formerly of the New York City branch, and who has been connected with the Remy company for several years.

The Stewart & Clark Manufacturing Company, Chicago, recently completed an addition to its large plant at a cost of $100,000. The new structure is being equipped with modern machinery and will be utilized for the manufacture of drop forgings employed in the construction of the Stewart speedometers. In the accompanying illustration is depicted the factory of the company including the new building.

D. K. Moore, vice president and one of the organizers of the American Distributing Company, Jackson, Mich., has accepted the position of general sales manager of the Western-Mott Company of Flint, Mich. Mr. Moore has been prominently identified with the automobile industry for the past 10 years, having specialized in the production and sale of axles, wheels, transmissions and steering gears. He will retain his interests in the American Distributing Company.

Plant of the Stewart & Clark Manufacturing Company, Chicago, Maker of Speedometers, Showing New Addition Constructed Recently.

The Federal Motor Truck Company, Detroit, maker of one-ton trucks, has purchased the land, buildings, machinery, etc., of the Van Dyke Motor Car Company, and the former concern will move its machinery into the new plant which it is estimated will increase its production to about 1000 cars a year. In the accompanying illustration is depicted the factory which is 60 by 512 feet. In addition to the buildings shown there are warehouses, test sheds and a power plant. The location favors shipping, being accessible to the Michigan Central, Wabash, Lake Shore and Grand Trunk railways, sidings existing from two of these roads.

The Lauth-Juergens Motor Car Company, Fremont, O., announces the sale of four one-ton and one two-ton trucks to Brink's Express, Los Angeles, Cal., which concern does a general express and transfer business. The following have been appointed agents: The Mutual Auto Company, Duluth, Minn.; A. S. Lascelles & Co., New York City for Australia; P. A. Brink, Los Angeles, Cal.

The States Auto Supply Company has been incorporated at Oskaloosa, Ia., with a capital of $50,000, the officers being as follows: President, D. P. McClure; vice president, C. W. Payne; secretary, A. O. Watland; treasurer, E. P. McClure. This concern will do a wholesale business in motor car accessories, covering the States of Iowa, Minnesota and Missouri, as well as those adjacent to them.

GAS ANALYSIS INSTRUMENT.

Proper carburetion is one of the most important factors in the operation of an internal combustion engine, and unless the vaporizer be set properly there is a decrease in the efficiency of the power plant as well as trouble developed in the nature of carbon deposits. The common practise of setting a carburetor is to change the amount of fuel and air until the motor appears to run satisfactorily on the mixture and this is done regardless of the proper proportions. It may be that too much gasoline is being employed and that the excess is not being converted into energy. There are certain stated proportions of air and gasoline and these percentages have been determined after years of study and experimentation.

A device for analyzing the gas has been designed by Joseph W. Hays, combustion engineer, is manufactured and marketed by the Combustion Appliances Company, Rogers Park, Chicago, and is known as the Coapco special gas analysis instrument. It is mounted in a steel carrying case, having outside dimensions of 13 inches high, seven wide and less than three thick. It weighs less than 13 pounds and may be carried in any position without spilling the fluids utilized in its construction.

The operation is simple and the gases may be tested in less than a minute. The method of checking these is as follows: A short piece of gas pipe or brass tubing is inserted in the muffler or exhaust member and the instrument suspended. The motor is started and by pressing a bulb connected with the device a sample of gas is drawn in and conveyed to the registering tube, where the amount of carbon dioxide, carbon monoxide, etc., is noted easily. If the mixture be not correct the carburetor is adjusted either for gas or air as the device indicates is necessary. Too much or little of either is noted readily and it is obvious that all guesswork in setting the vaporizer is eliminated.

If it be desired to make a combustion test upon the road, all that is necessary is to tap a cock into the muffler or exhaust pipe and connect the instrument by means of a rubber hose. The former may then be taken into the tonneau and samples taken while the car is in operation and at any speed and over all road conditions and grades. In addition to ensuring a correct mixture the device makes for economy as rich mixtures are instantly detected and considerable time saved in the garage in adjusting new or old carburetors.

ISSUES ANNIVERSARY NUMBER.

The Team Owners' Review, a publication devoted to the teaming, transferring and express trade, and which is published in Pittsburg, Penn., has issued an anniversary number which is neatly printed and handsomely illustrated. It contains information pertinent to the transportation industry.

DEMOUNTABLE RIMS FAVORED.

That there is a growing tendency to fit demountable rims as a part of the regular equipment was noted at the recent shows in New York City. At the Grand Palace exhibit nearly 25 per cent. of the commercial vehicles shown were fitted with this type of rim and many of these were Firestones, made by the Firestone Tire & Rubber Company, Akron, O.

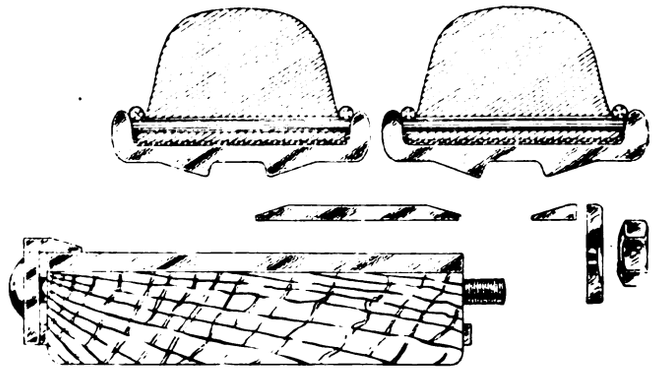
Undisputed Leadership in



"Firestone"

Leads Again at the Truck Shows

Has More Equipment Than Any Others at the New York Shows, by a wide margin.

A complete line of truck tires for every type of car, size of load and condition of service on Removable and Non-Removable rims. Firestone Truck tires have led the industry from the very beginning in Accuracy of Design, Volume of Output and Quality of Tire. Undisputed leadership has particularly qualified the Firestone company to offer the only complete and fully proven line.

Single and dual Heavy Duty tire for resiliency. Economical in car up-keep. Old and S. A. E. standards. *Note:* Both dual tires can be taken off without removing the wheel.

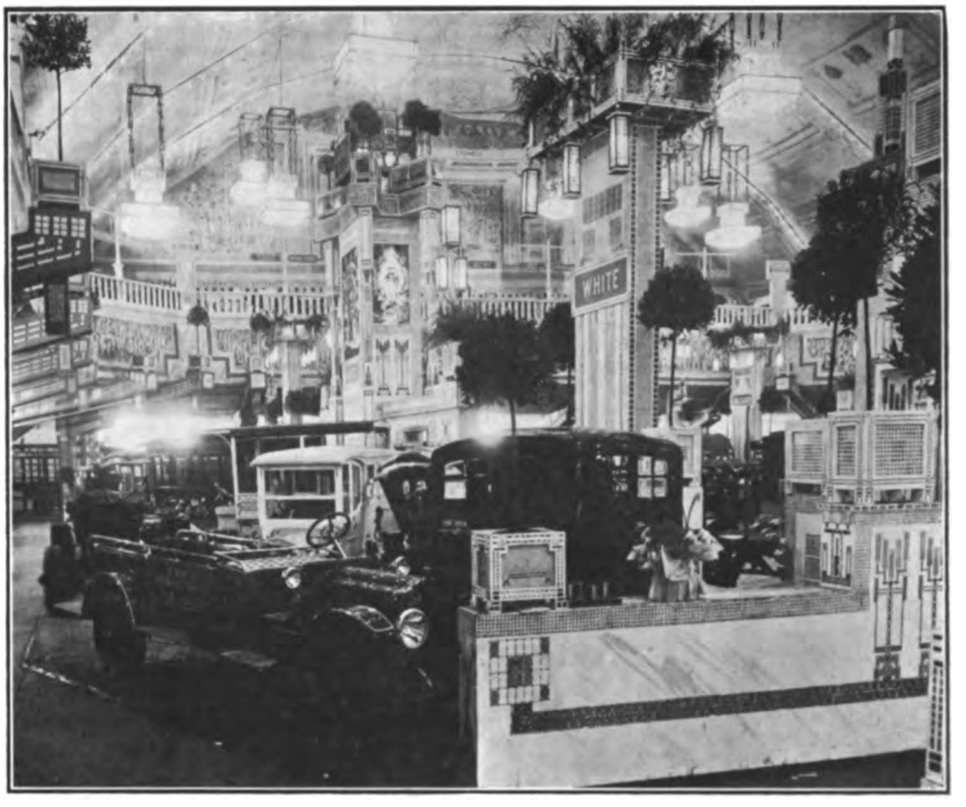
The MOTOR TRUCK
Devoted to Motor Driven Business Vehicles of All Classes.



VOL. III. PAWTUCKET, R. I., MARCH, 1912 No. 3

THIRTY-FOUR NEW MODELS AT CHICAGO.

Many Western Manufacturers Make Initial Showing at This Display---Standard Construction Prevails, Though Novel Designs Are Presented---Attendance Exceeds Last Year.

ASIDE from being the largest exhibition of commercial motor vehicles yet held by the industry the second annual separate showing of industrial transports in the Coliseum and First Regiment Armory at Chicago, Feb. 5-10, was of decided importance. There were 81 different makes on view, of which 74 were gasoline driven machines and seven electric. Thirty-four manufacturers were not represented at the shows in New York during the preceding month, and of these 32 plants are located in the Middle West.

The National Association of Automobile Manufacturers, under whose auspices the event was held, left no stone unturned to make this the most representative showing of motor trucks in the country, and the success of the enterprise was assured by the generous response of the makers. The management, under the direction of S. A. Miles, was not content with providing the opportunity for making display, but carried on a campaign which had its beginning long before the 1911 show, which resulted in greatly augmenting the attendance upon this event.

Scene in the Coliseum During Progress of Chicago's Commercial Car Show, Indicating Beauty of Decorative Scheme.

The plan was in the nature of an educational campaign, in which a systematic correspondence was arranged between the committee in charge and the people of that section of which Chicago is the metropolitan commercial centre. Men in all walks of life were reached by carefully worded letters bringing out the particular benefits to be derived from the use of industrial transports in the line of business with which they were connected. These contained arguments and facts based upon what has been accomplished in different sections of the country, under varied conditions, and the result was in effect a personal invitation to attend the show and study the subject at first hand by comparing the machines on display. That this plan was a success is indicated by the announcement that the total attendance during the week exceeded that during the week in 1911 by 40 per cent. The volume of business transacted was proportionately large. In the matter of decorations, the Chicago show has become recognized as the most elaborately staged of any American automobile exhibition. Of course, this applies to the pleasure car display, since that is held first but the same attractive setting is used for both. This year, the Coliseum proper was so completely transformed that even the show management was at a loss to give the scheme a distinctive name. Accompanying photographs give a slight indication of its remarkable beauty.

A mosaic palace is the term which comes nearest to describing it. The roof was a massive painted arch, from which were suspended three rows of lanterns of square design and great size. Underneath, a wide main aisle divided the show spaces in half, those in turn being sub-divided by superstructures, suggesting immense clock towers surmount-

Digitized by Google

ed by small squared spaces with four projecting platforms carrying potted palms. On either side of these clock towers was a lower structure terminating in small turrets, also carrying potted plants.

The treatment of the balcony, where accessories were shown, and the Coliseum Annex, was similar in design but not so elaborate in its execution. The First Regiment Armory utilized some of the decorative features which did duty in the Coliseum last year. All told, the general effect was most bewildering at first.

It has been stated that there were 34 makes of machines on display which were not seen in New York. But one of these was electric. It follows that the electric car situation is not greatly changed as a result of the Chicago show. Reference is had particularly to those vehicles which have been arranged for public inspection in comparison with other makes.

With respect to the gasoline driven machines, it will prove of interest to add those shown at Chicago with those seen in New York and attempt to arrive at some idea of the trend of design. Of course, it will be admitted that this

General View of the Main Floor in Chicago Coliseum, with Motor Trucks Disposed for Inspection.

term is somewhat abused. In the main, motor trucks follow standard construction, much the same as do pleasure vehicles. The day of experimentation is not past, and it will be noted in a continuation of this discussion elsewhere that some new things were brought to light at Chicago.

It will be remembered that there were three worm driven trucks on display in New York. These were the Pierce-Arrow, which adopted this method of final drive a year ago, at the Madison Square Garden exhibit, and the Newark and Rowe at the Grand Central Palace. Chicago added three more—Blair, Great Dain and Smith.

Among the friction driven machines at New York were noted: Cartercar at the Garden, and Best, Commerce and Poss at the Palace. The Great Dain, Service and Utility were added at Chicago.

Accessibility of the power plant has been worked out in a number of ways, as was explained with reference to the eastern displays. At least two more novelties were uncovered at the Coliseum. Two more trucks appeared with the foreign placing of the radiator and the Renault type of hood. Still other features will be noted herein.

Perhaps one of the most notable results of the three shows is the adoption of the foreign policy with respect to the location of the motor elsewhere than under the hood. This may mean that the power plant is under the floor, under the seat, in the cab, or with a hood so short as to prove almost negligible.

Not counting the two three-wheeled vehicles, there were 25 makes of gasoline cars at Madison Square Garden, 32 at Grand Central Palace and 33 at Chicago which were not seen at either of the other two shows. Of the 25 at the Garden 10 were with motors under the hood, 11 under the floor, seat or amidships, and four in the cab. At the Palace, 18 were under the hood, and 14 elsewhere. Of the 33 new trucks at Chicago, 18 were under the hood, 12 under the floor, etc., and three practically within the cab. In one or two cases the hood was so short as almost to bring these makes within the other classifications. This brings the total to 90 different manufacturers, who have decided this question as follows: Under the hood, 46; under the floor, etc., 37; in the cab, seven. It should not be considered, however, that this is an exact representation, since some makers still retain the hood with certain models, having adopted other locations with their newer productions only.

Closely allied with the subject of motor location is that of placing the driver. While the New York show seemed to indicate a tendency toward the left hand drive, so-called, the results at the conclusion of the Chicago display do not seem to warrant this assumption. However, the percentage of trucks thus arranged is sufficiently large to merit attention. Eighteen of the 25 makes shown at the Madison Square Garden were with right hand location of the driver, while seven showed the opposite to be true. At the Grand Central Palace, 18 were at the right and 14 at the left. Of the new makes at Chicago, 24 were the total of 90 again, 60 were with right and nine were left. Taking right hand drive and 30 with left. The same rule applies as with the motor location, since some makers fit vehicles with either right or left hand drive, as desired, although in each such case, the maker has been listed as offering left hand drive in the above compilation. Thus, while the list shows one-third with left hand drive, this is not exactly warranted when the total production is taken into account.

Coming next to the matter of control levers, it will be seen that there exists considerable difference of opinion here as well. Of course, with the left hand placing of the driver, the levers must be taken away from the right side of the truck, although it does not follow necessarily that the levers will be operated with the left hand. When this is not the case, they must be located in the centre, and it is to be noted that some makers have adopted this plan, even though the driver is still retained at the right. The reason, therefore, lies in the opportunity to permit easier ingress and egress to the driver's seat.

Eighteen of the 25 makes seen at Madison Square Garden had the levers at the right, and this number exactly

Digitized by Google

Impression Conveyed by Mosaic Palace Effect with Reference to Individual Exhibits.

corresponds with those which had right hand drive. Six had levers at the left, while one had these in the centre. Eighteen of the 32 at the Grand Central Palace also had right hand location of levers, again corresponding with the number of right hand driven machines. Four had levers at the left and 10 in the centre. Of the 33 new makes at Chicago, 22 had levers at the right, one at the left and nine in the centre. In the total of 90, 68 were with right hand control, 11 with left hand, and 20 with central. It will be noted that this accounts for all but one, and that had the control levers mounted on the steering column.

The 82 makers who displayed at Chicago had on view 226 completed vehicles and chassis. Of these 11 cars and six chassis were electric; 209 were gasoline driven, and of these five had one-cylinder engines; 41 two-cylinder; six three-cylinder; 156 four-cylinder, and one six-cylinder. Detailed description of the new models not seen at New York will be found in the succeeding pages.

SAMPSON CARS EFFECT LARGE SAVING.

An instance of economy effected by the use of commercial vehicles in municipal service is noted in Kansas City, where the authorities advertised contracts for six motor trucks about a year ago. After considerable keen competition the award was made to the United States Motor Company, which markets the Sampson cars, made by the Alden Sampson Manufacturing Company, Detroit. Soon afterward three two and three three-ton trucks were placed in service in the street cleaning department.

It was noted by Commissioner W. C. Weaver that each of the machines displaced from seven to nine horse drawn vehicles and that at the end of three months the average cost of maintenance for the six automobiles was $125.25 a month, compared with $960 for the horse drawn equipment, which each of the Sampson vehicles replaced. Figuring at this ratio it was estimated that the motor equipment effected a saving of $5005.50, this amount representing the cost of the cars.

These figures, however, do not comprise depreciation or tire renewals, but even considering these, there would remain a substantial sum in favor of the motor vehicle. The two-ton cars are utilized to gather up cans of street cleanings and to carry and dump the contents at the municipal grounds. In special emergencies, such as at large fires, they are employed to assist the fire department. Frequently the sewer department is aided. Two of the larger vehicles are employed in hauling asphalt, crushed rock, sand and paving materials. They are fitted with a self-dumping body by means of which the driver may dump a three-ton load unassisted in three minutes. The other machine is employed in general street repairs, carrying laborers, tools, material, etc.

VELIE TRUCK ON COUNTRY RUN.

To inaugurate the 1912 commercial car season the Chicago branch of the Velie Motor Vehicle Company, Moline, Ill., sent a three-ton truck loaded with a 1912 Velie speedster to Milwaukee, Wis., a distance of 124 miles. The car left Chicago Sunday, stopping over night at Racine, arriving at its destination the next morning at 10. The trip was made for the purpose of demonstrating the efficiency of the Velie on country roads during the winter. The car averaged 10.2 miles an hour and 4.1 miles to a gallon of fuel. It experienced extreme cold weather and bad roads as well as numerous steep grades. Throughout the test the automobile performed consistently.

WHITE PATROL CAR FOR NEW HAVEN.

After considering carefully the practicability of the motor car for municipal service the police commissioners of New Haven, Conn., have placed an order with the White Company, Cleveland, O., for a patrol wagon. It will be a standard 1500-pound chassis, equipped with a four-cylinder motor of 30 horsepower, and the body will be constructed on the same lines as other White vehicles of this type in service in other cities.

An Alcove Setting in Which the Oriental Design Is Still Further Accentuated.

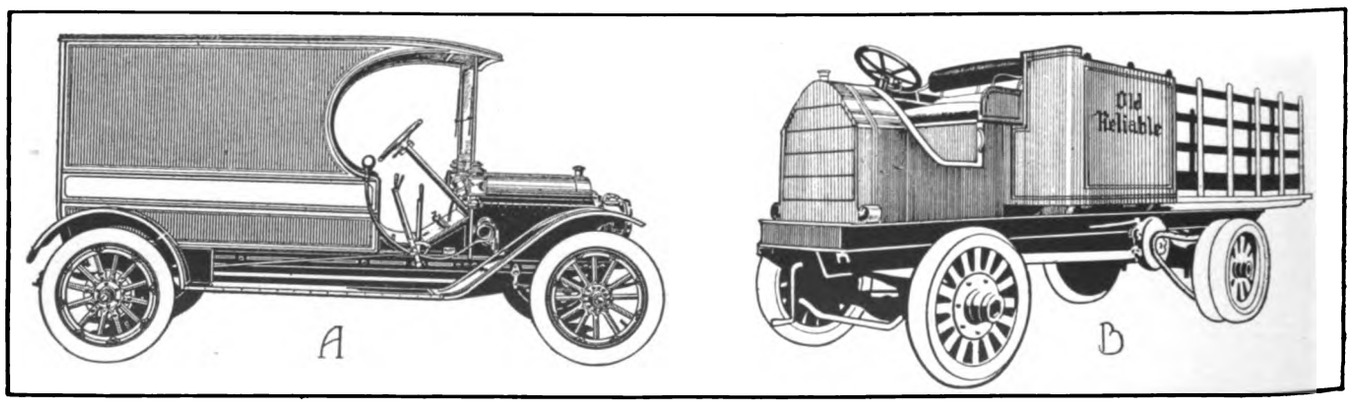
Digitized by Google

New Models Shown at Chicago

OF THE 34 makes of trucks displayed at Chicago, which were not seen at the shows in the East, 33 were gasoline and one electric. Some of these were entirely new, never having been exhibited at any show previously. The following descriptions are intended to present the particular features claimed for each, indicating as well the departures from lines which have been noted heretofore in the older products. The machines exhibited at the New York displays were treated in a similar manner in the issue of MOTOR TRUCK for February.

Adams.

The Adams Bros. Company, Findlay, O., displayed four four-cylinder one-ton Adams trucks. Motor is in front under a Renault type hood, with radiator at the back, following foreign practise. Cylinders are cast en bloc with bore of 3.875 inches and stroke of five. Valves are all on the right side. Cooling is by water, with centrifugal pump and flat vertical tube radiator. Ignition is by Eisemann magneto and storage battery. Lubrication is by splash and force feed. Clutch is a Wells dry disc. Transmission is selective, three speeds forward and reverse. Drive is by double side chain. Service brake on the jackshaft operated by pedal; two emergency brakes on rear wheels, operated by hand lever. Springs are semi-elliptic, front and rear. Wheelbase is 121 inches; tread, 56; tires, 36 by three inches front, and 36 by 3.5 in rear. Chassis weight is 3200 pounds. Driver is at the left with levers in the centre.



A particular feature of the construction is the mounting of the engine on a sub-frame and the use of a long propeller shaft connecting the change speed mechanism, which is supported in front by a single cross member from one point, and at two points on another cross member at the rear. The jackshaft bearings are bolted to the underside of the frame members. Full accessibility is afforded by lifting the hood from the front. This with the foreign radiator mounting gives the truck a decidedly distinctive appearance. However, it will be seen that for the most part the construction follows standard lines.

Avery.

The Avery Company, Peoria, Ill., exhibited three four-cylinder vehicles of two, three and five tons capacity. With the two and three-ton models, the motor is located under a hood, while the driver and levers are placed at the right and beside the rear portion of the hood. Cylinders are cast separately, with bore of 4.75 inches and stroke of five. Cooling is by water, with centrifugal pump and either honeycomb or vertical tube radiator. Ignition is by storage battery, Eisemann coil and Eisemann dual automatic magneto. Lubrication is by force feed gear pump and splash. Clutch is a multiple disc, 11 large steel discs housed in the flywheel, dust proof and running in oil. Transmission is selective, three speeds forward and reverse. Drive is by double side chains. Service brakes are internal expanding on countershaft, operated by pedal; emergency, internal expanding on rear wheels, operated by hand lever. Springs are semi-elliptic all around. Wheelbase is 140 inches; tread, 62 in front and 68 in rear; tires, solid rubber, 36 by four-inch front and 36 by 3.5, dual, rear, on the two-ton, and 38 by five, front, and 38 by four, dual, rear, on the three-ton. Chassis weight, 5500 pounds for two-ton and 5700 for the three.

In the main the five-ton model does not differ materially from the smaller machines. The motor is of the same size, but is mounted on a sub-frame with three point suspension, the location being under the floor. The transission is made a unit with the jackshaft housing. The driving chains are enclosed in a steel case. The construction throughout necessarily is heavier. While the wheelbase is the same the tread is 62 inches in front and 72 in the rear. Tires are solid, 38 by six inches in front, and 38 by five, dual, rear. Chassis weight is 7250 pounds.

The above specifications may be regarded as standard, although the three-ton vehicle on display was equipped with cast steel rim wheels and wood plug tires, which also are furnished as regular equipment upon order. The net weight of the chassis in this case is 5875 pounds.

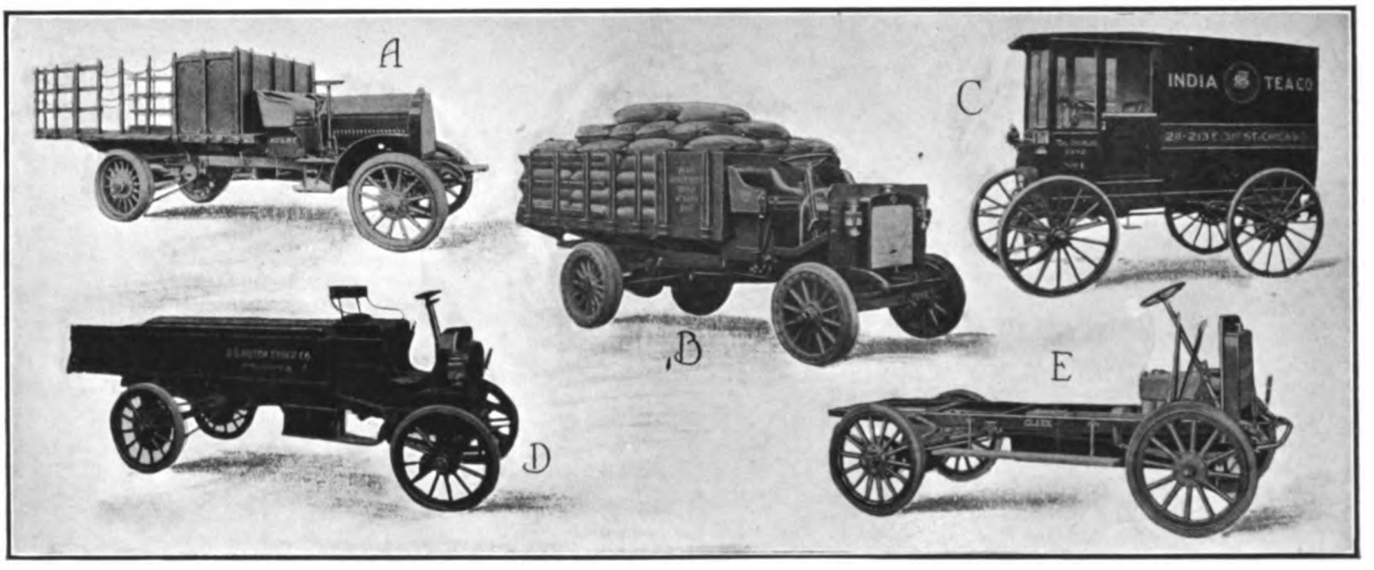
Two of the New Models Displayed at Chicago: A, 1500-Pound Dorris Wagon; B, 3.5-Ton Reliable Truck.

Digitized by Google

Bessemer.

The Bessemer Motor Truck Company, Grove City, Penn., presented one four-cylinder Bessemer truck, rated at one ton. The motor is in front under a hood, with driver at the left, and central control levers. Cylinders are cast en bloc with bore of 3.75 inches and stroke of 5.25. Cooling is by water. Ignition is by Bosch dual system high-tension magneto. Lubrication is by force feed. Clutch is a cone with cork insert. Transmission is selective, three speeds forward and reverse. Drive is by double side chain. Two sets of brakes are fitted, expanding and contracting on rear wheels. Springs are semi-elliptic in front and platform in rear. Wheelbase is 107 inches, tires, 34 by three inches in front and 34 by 3.5 in the rear.

Power is transmitted through the three speed transmission to a jackshaft bolted to the frame and thence through side chains to the rear wheels. The spring hanger and end of jackshaft housing are integral, permitting the removal of the jackshaft by loosening two bolts and a cap. Particular attention has been paid to the matter of accessibility throughout. An American self-starter is fitted.



Blair.

The Blair Manufacturing Company, Newark, O., showed three four-cylinder delivery wagons and a chassis, all of one-ton capacity. The motor is under the floor with driver and levers at the right. Cylinders are cast en bloc with bore of 3.75 inches and stroke of five. Cooling is by water, thermo-syphon system with honeycomb radiator. Ignition is Eisemann high-tension magneto. Lubrication is by gear pump. Clutch is a multiple disc, running in oil. Transmission is selective, three speeds forward and reverse. Drive is by shaft. Brakes are double expanding on rear wheels. Springs are semi-elliptic in front and full elliptic with auxiliary coil springs in the rear. Wheelbase is 100 inches; tread, 56; tires, 36 by three inches front and 36 by 3.5 rear. Chassis weight is 3000 pounds.

As special features, it is claimed that the motor is one of the few block designs having three main bearings, which is held to make for rigidity and long life. The motor and transmission are mounted on a sub-frame, and it is only necessary to remove the foot plates to work on any part of the mechanism. A drawbar is provided upon order, by means of which it is possible to utilize the truck as a tractor for hauling other light vehicles.

Diamond T.

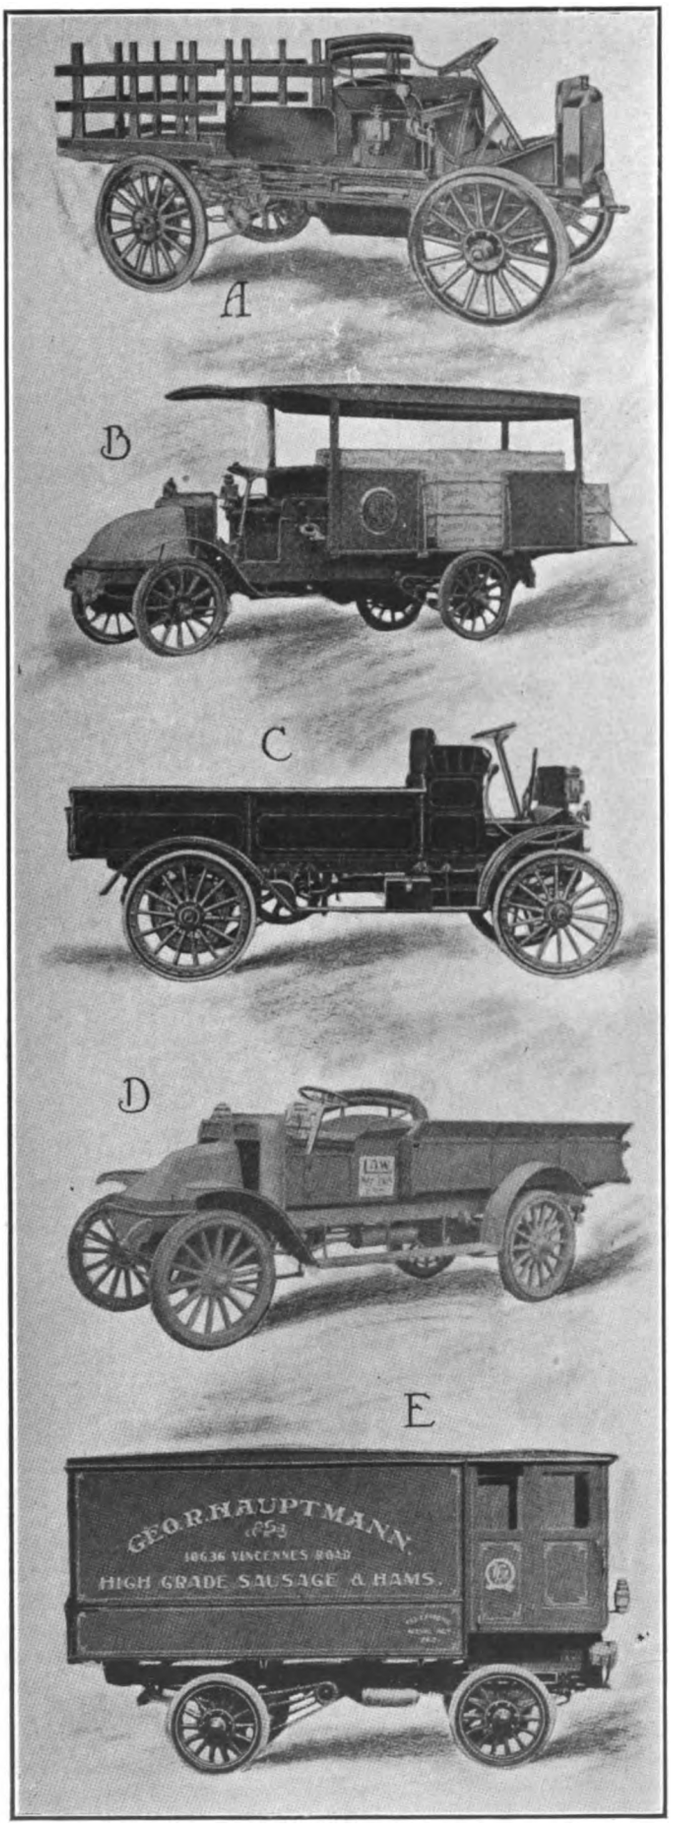
The Diamond T Motor Car Company, Chicago, presented one complete four-cylinder wagon and a chassis, both of five

A Group of Chicago Exhibits: A, Two-Ton Avery; B, 1.5-Ton Blair; C, 1000-Pound Mercury; D, One-Ton United States; E, One-Ton Clark.

its one-ton four-cylinder chassis. The motor is under a hood beside the driver, who is located at the right with right hand levers. Cylinders are cast en bloc with bore of 4.125 inches and stroke of 5.25. Cooling is by water with centrifugal pump and square tube honeycomb radiator. Ignition is by Bosch magneto and dry cells. Lubrication is by positive plunger pump and with constant lever. Clutch is a cone with cork inserts. Transmission is selective, three speeds forward and reverse. Drive is by worm gear and no universals. Two sets of brakes are fitted, contracting on rear wheel hubs and propeller shaft drum. Springs are semi-elliptic in front and platform in rear. Wheelbase is 114 inches; tread, 60; tires, 34 by four inches front, 34 by three inches, dual, rear. Chassis weight is 4000 pounds.

As will be noted, this is one of the makes which presents a worm drive this year. The worm has four threads and is of the Hindley type. A 28-degree angle is employed, and there are four separate and distinct bearings. Of these, two on either side are thrust, while the others are annular. The worm is made demountable from the rear by the removal of two holding and two housing bolts.

Clark.



The Clark Delivery Car Company, Chicago, had on view tons capacity, although a three-ton model is produced by the same concern. The motor is in front with driver and levers at the right. In the vehicle shown the cylinders are cast in pairs, with bore of five inches and stroke of 5.5. Cooling is by water. Ignition is by Bosch dual system. Clutch is a multiple disc, steel plates running in an oil tight case. Transmission is selective, three speeds forward and reverse. Drive is by double side chain. Wheelbase is 144 inches; tires, 36 by six, demountable, single in front and dual rear.

The construction is substantial throughout and of simple design, the frame being heavy and well braced at all vital points. The motor is suspended on a sub-frame and heavy plates are set between this and the main frame, acting as brace and pan at the same time. It may be added that the three-ton model carries the same specifications as above, with the exception that the springs are lighter and the tires are 36 by five inches.

Dorris.

The Dorris Motor Car Company, St. Louis, heretofore known as a pleasure car maker, displayed one four-cylinder Dorris 1.5-ton truck and a 1500-pound chassis. The motor is in front under a hood and the driver and levers at the

Digitized by Google

Shown at Chicago: A, 1500-Pound Little Giant; B, One-Ton Adams; C, One-Ton Utility; D, 1.5-Ton L. A. W.; E, Two-Ton Harder.

right. Cylinders are cast in pairs with bore of 4.375 inches and stoke of five. Cooling is by water. Ignition is by Bosch magneto and dry cells. Lubrication is by the constant level splash system with gear pump and oil reservoir in the bottom of the crankcase. Clutch is a special Dorris dry plate, multiple disc, housed in the fan flywheel. Transmission is selective, three speeds forward and reverse. Drive is by propeller shaft with double universal joint and straight line drive under load. Brakes are internal expanding and external contracting on rear wheels. Springs are semi-elliptic in front and three point platform in rear. Wheelbase is 132 inches; tread, 56; tires, 35.5 by 4.5 inches, all around.

Several features are noted, among which may be mentioned the fitting of a centrifugal governor, acting on the butterfly valve in the intake pipe, set to limit the speed of the truck to 12 miles an hour. A water jacket placed around the inlet pipe from the carburetor to the branch is connected with the water circulating system and by being kept warm supplies a warm mixture to the motor at all times. Another refinement is the use of a Prest-O-Starter. Mention also may be made of an auxiliary cross spring in the rear, carried under a cross member.

Great Dain.

Joseph Dain, Ottumwa, Ia., brought out a new chassis in the four-cylinder Great Dain of one-ton capacity. The driver is located at the left with centre control. The cylinders are cast en bloc with bore of 3.75 inches and stroke of five. Cooling is by water, with pump and honeycomb radiator. Ignition is by K-W high-tension magneto. Lubrication is by force feed. Clutch is a cone. Transmission is dual friction. Drive is by shaft and full floating worm. Two sets of brakes are fitted, contracting and expanding. Springs are semi-elliptic in front and three-quarter platform in the rear. Wheelbase is 100 inches; tread, 56.5 inches; tires, 36 by 3.5 in front, and 36 by four in rear. Chassis weight is 3000 pounds.

The transmission scheme is of decided interest, inasmuch as the friction discs are employed only for low speed and reverse, the direct drive being through the cone clutch. This whole assembly is made a part of the motor, providing a unit power and transmission plant. In addition, it is claimed for this construction that it provides a perfect three point suspension, power being transmitted at all times directly from the engine to the rear axle in a straight line, no universal joints being used.

The transmission proper consists of two discs set at an angle to each other, which on low speed and reverse are rotated by the rim of the flywheel being brought into frictional contact with their edges. A friction wheel slideably connected with the propeller shaft and mounted between the discs, receives the power from the faces of the discs. When shifting the friction wheel across the faces of the discs, or to disengage the power when using the transmission, the driver may by a simple movement of the foot, lift the friction wheel out of engagement with the discs and thereby release the contact between it and the faces of the discs. The discs being mounted with their faces at an angle to each other, or in other words, the friction wheel being in wedging contact with the faces of the discs, makes it possible to relieve the frictional contact by lifting the friction wheel instead of moving the discs.

To shift from low to high speed, or from transmission to direct drive, the friction wheel, which carries one member of a cone clutch, is moved out of contact with the faces of the discs and into engagement with the other member of the cone clutch formed in the flywheel. Doing this moves the flywheel out of contact with the edges of the discs and leaves them dormant. The power is disengaged when on the direct drive by releasing the clutch with the foot lever.

Digitized by Google

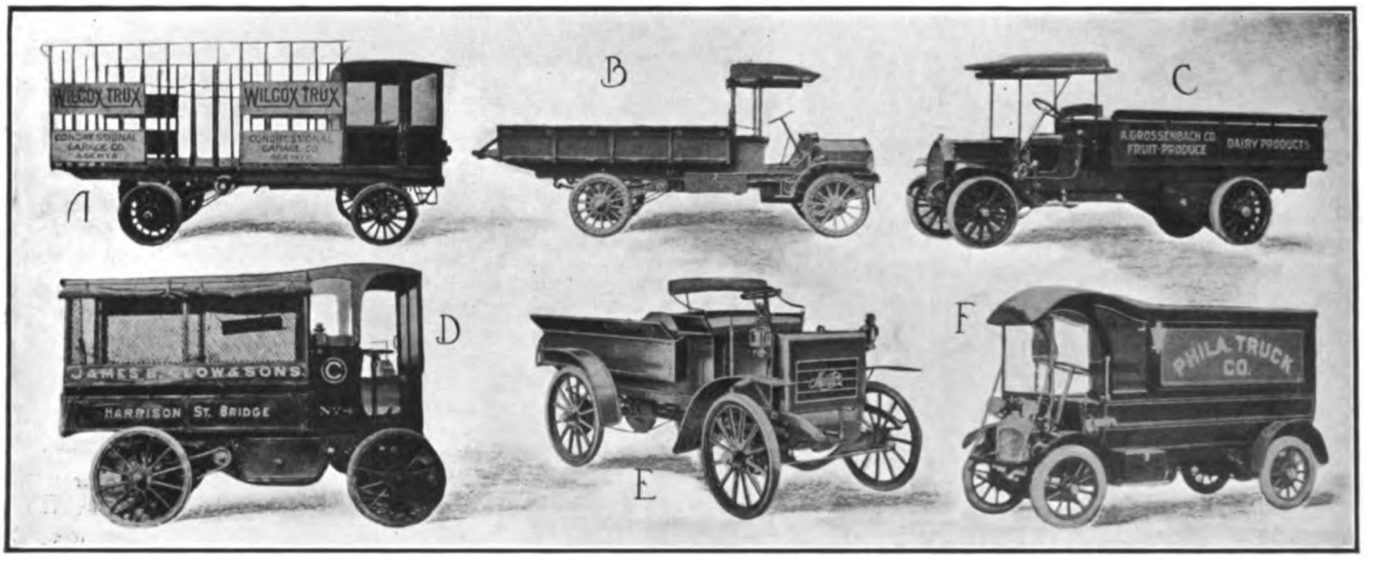
With reference to the three point suspension, it may be said that the drive shaft is encased in a tube which has a slip joint near the rear end. The torque is cared for by this tube, and there are means of taking this away from the drive shaft, these being in the nature of buffers located immediately in front of the back axle. The slip joint is designed to prevent any tendency to transmit radial strains through the transmission or motor.

Final drive is by a Hindley full floating worm drive axle, in direct line with the drive shaft and motor. The axle itself is of the semi-floating type, and an auxiliary cross spring is carried on the back cross member, this being braced on either side to the frame member by pressed steel straps, concaved to add strength and rigidity.

Harder.

The Harder Auto Truck Company, Chicago, presented a two-ton stake, three-ton furniture van and a combination chemical fire wagon. In these the motor is located under the floor with driver and levers at the right. The four cylinders are cast in pairs and are of four different sizes—four by four inches, 4.25 by 4.75, 4.75 by five, and five by six. Cooling is by water with vertical tube radiator. Ignition is by Mea magneto. Lubrication is by force feed and splash. Clutch is of special design, comprising 15 cone shaped plates. Transmission is selective, three speeds forward and reverse. Two sets of brakes are provided, internal and external. Wheelbase is 110 inches; tread, 58; tires, 32 by four in front and 34 by five in rear.

Several special features are noted. The radiator is hinged on the left side, and uncoupling two hose connections makes it possible to swing this member as in opening a door. The power plant is then fully accessible for adjustment or removal. The spring system also is unusual. The front members are of the semi-elliptic type but of special construction. The rear suspension is of the platform type, also special, and instead of a cross spring at the rear there is what is termed an equalizing traction bar. This is swivelled in the centre of the frame with the ends hung on spring shackles, so that the tendency is for the floor of the truck to remain horizontal even when one wheel drops into a hole.



Indiana.

The Harwood-Barley Manufacturing Company, Marion, Ind., displayed one one-ton four-cylinder Indiana truck. The motor is in front under a hood, with driver at the right and centre control. The cylinders are cast singly, with bore and stroke of four inches. Cooling is by water, with gear pump and flat tube radiator. Ignition is by Bosch magneto. Lubrication is by the splash and pump system. Clutch is a multiple disc. Transmission is selective, three speeds forward and reverse. Drive is by side chains. Service brake is on the jackshaft, and emergency on the rear wheels. Springs are semi-elliptic all around. Wheelbase is 120 inches; tread, 58; tires, 34 by three in front, and 34 by four in rear. Chassis weight is 2850 pounds.

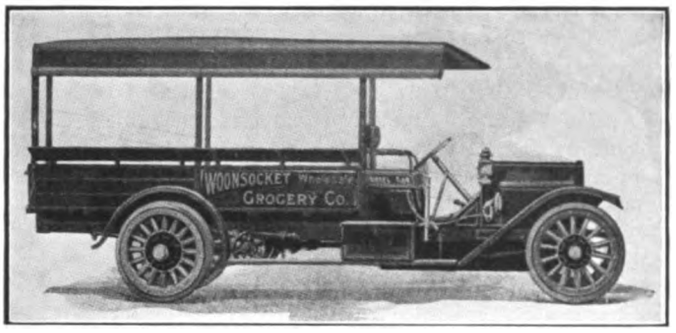
Although a new design, it will be noted that this product does not depart greatly from accepted standard construction. The maker is prepared to furnish all types of special bodies upon order, although the regular equipment is an express wagon with carrying space four feet two inches in width and five feet 9.5 inches in platform length.

International.

The International Harvester Company of America, Chicago, exhibited three of its two-cylinder International auto wagons. The motor is located amidships with driver and levers at the right. The cylinders are opposed, with bore and stroke of five inches. Cooling is by air, with fans at the sides of the cylinders driven by belts from the flywheel. Ignition is by Heinze magneto and battery. Lubrication is by a 10-feed mechanical oiler. Clutch is of the expanding band type. Transmission is planetary, with two speeds and reverse. Drive is by chains. Service brake is on the differential and emergency on the rear wheels. Springs are full elliptic all around. Wheels are of the buggy type.

Six Additional New Models: A, Three-Ton Wilcox; B, 1.5-Ton Indiana; C, Two-Ton Stegeman; D, One-Ton Schmidt; E, 1500-Pound Monitor; F, 1500-Pound Philadelphia.

Jeffery.



Although the Thomas B. Jeffery Company, Kenosha, Wis., is well known as the maker of Rambler pleasure cars, its trucks have been named Jeffery. One four-cylinder 1.5-ton vehicle was shown. The motor is under the seat, with driver at the left and central control levers. Cylinders are vertical and the horsepower rating is 38. Cooling is by water. Ignition is by Bosch high-tension magneto. Lubrication is by combination force feed and splash. Transmission provides three speeds forward and reverse. Drive is by side chains. Service brake is on the jackshaft and emergency on the rear wheels. Springs are semi-elliptic all around. Wheelbase is 120 inches; tires, 34 by four in front, and 34 by three, dual, rear.

KisselKar.

One of the most complete lines displayed was the KisselKar, made by the Kissel Motor Car Company, Hartford, Wis. This included the 1500-pound, one, two, three and five-ton

Digitized by Google

models. In these the four-cylinder motor is located in front under a hood, with driver and levers at the right. In the smaller vehicles the bore is 4.5 inches and stroke, 4.75, while in the three and five-ton models the bore is 4.875 and

Two-Ton KisselKar Truck at Chicago Display.

the stroke five. Cooling is by water, with centrifugal pump, square tube radiator and belt driven fan. Ignition is either by Mea or Bosch magneto. Lubrication is by splash. Clutch is a leather faced cone, with adjustable spring inserts underneath the leather, permitting gradual engagement. Transmission is selective, four speeds forward and reverse. Drive is by chains. Service brakes are contracting on countershaft; emergency, internal expanding on rear wheels. Four semi-elliptic springs are employed.

In the two-ton vehicles the wheelbase is 140 inches; tread, 60; tires, 34 by four, front, and 36 by 3.5, dual, rear. Chassis is 18 feet over all and weighs 4450 pounds. In the three-ton, wheelbase is 144 inches; tread, 68; tires, 36 by four, front, and the same size, dual, rear. Chassis is 19 feet four inches, and weighs 5300 pounds. In the five-ton, the wheelbase is 156 inches; tread, 69; tires, 36 by five, front, and 40 by six, dual, rear. Chassis is 20 feet six inches, and weighs 6000 pounds.

The maker of this line claims there is a KisselKar truck or delivery wagon designed to give the lowest cost service, whether it be wanted for hauling heavy freightage, fast delivery of lighter merchandise, or for long or short hauls. Reserve capacity, reserve power and reserve structural strength are held to give the widest latitude of service. In addition it is stated that the excess ability is not gained at the sacrifice of low fuel cost, for in competition the KisselKar has demonstrated its ability to master all road conditions under excess loads at from 15 to 20 per cent. less fuel consumption than others.

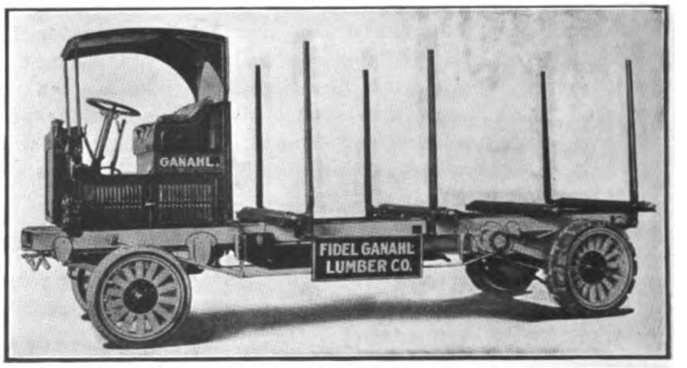
L. A. W.

The L. A. W. Motor Truck Company, Findlay, O., showed one four-cylinder 1.5-ton truck. The motor is in front under a Renault type hood, and driver either at the right or left with central control levers. The cylinders are cast en bloc with bore of 3.75 inches and stroke of five. Cooling is by water, thermo-syphon system, with radiator behind the motor in front of the dash. Ignition is by Eisemann magneto. Lubrication is by force feed through a hollow crankshaft. Clutch is a multiple disc, dry. Transmission is selective, three forward speeds and reverse. Brakes are external and internal. Springs are semi-elliptic all around. Wheelbase is 130 inches; tread, 58; tires, 38 by 3.5 front, and 40 by four in rear. Chassis weight is 4000 pounds.

A special feature is the final drive scheme, wherein the drive is through spur gears first, thence through the conventional bevel gear mechanism to the rear wheels. This is done to obtain the gear reduction without enlarging the differential housing. The Renault type hood and foreign radiator placing puts the L. A. W. in the distinctive class.

Little Giant.

The Chicago Pneumatic Tool Company, displayed three two-cylinder vehicles and a chassis, rated at one ton each. The motor is located under the seat with driver and levers at the right. The cylinders are opposed with five-inch bore and four-inch stroke. Cooling is by water, thermo-syphon system, with flat vertical tube radiator. Ignition is by Splitdorf magneto. Lubrication is by plunger system. Clutch is a multiple disc. Transmission is planetary, two speeds forward and reverse. Drive is by side chains. Brakes are internal expanding and external contracting on rear wheel hubs. Springs are three-quarter elliptic in front and full elliptic in rear. Wheelbase is 91 inches; tread, 56; tires, 36 by two in front, and 36 by 2.5 in rear. Chassis weight is 2035 pounds.



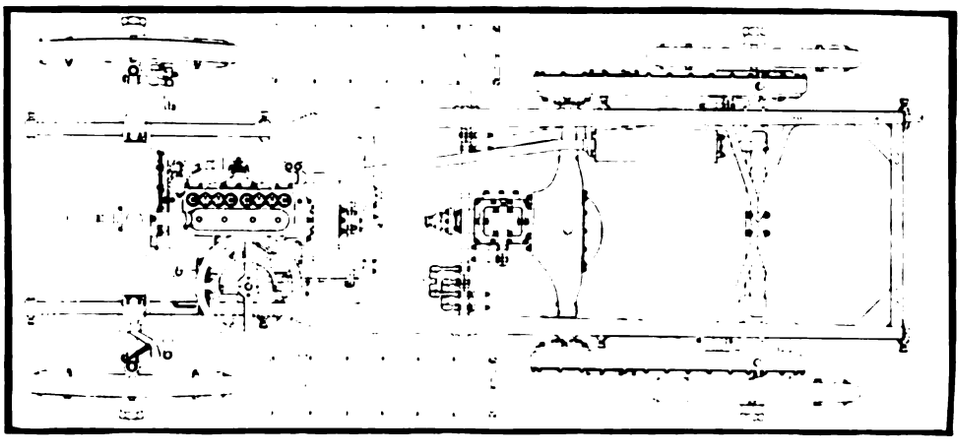
Mercury.

The Mercury Manufacturing Company, Chicago, presented three two-cylinder Mercury vehicles of 1000 pounds capacity. The motor is under the seat with driver and single control lever at the right. The cylinders are horizontal opposed, with bore of 4.25 inches and stroke of four. Cooling is by air. Ignition is by jump spark, dry cells and storage battery. Lubrication is by force feed and splash. Clutch is a single disc. Transmission is planetary, two speeds forward and reverse. Brakes are internal expanding. Springs are full elliptic, front and rear. Wheelbase is 85 inches; tread, 56; tires, 38 by 1.75 inches in front and 40 by 1.75 inches in rear. Wheels are of the buggy type. Chassis weight is 1500 pounds.

Mogul.

The Mogul Motor Truck Company, Chicago, showed two four-cylinder Mogul vehicles. One was a six-ton lumber truck and the other a two-ton stake wagon. Motor is under the floor and driver and levers at the right. Describing the larger vehicle first: The cylinders are cast in pairs with 5.25-inch bore and 5.75-inch stroke. Cooling is by water, centrifugal pump, adjustable radiator fan and honeycomb radiator. Ignition is by high-tension magneto. Lubrication is by splash. Clutch is a multiple disc, alternate discs made of bronze and steel, running in an oil tight housing. Transmission is progressive, three speeds forward and reverse. Two sets of equalizing brakes are located on the rear hubs, both internal expanding. Springs are semi-elliptic, front and rear. Wheelbase is 155 inches; tread, 60.5; tires, 36 by seven inches in front and 40 by six, dual, in rear.

The two-ton model has cylinders cast en bloc, with bore of 4.125 inches and stroke of 5.25. Transmission is selective, three speeds forward and reverse. Service brakes are mounted on the jackshaft; emergency on the rear



Six-Ton Mogul with Special Lumber Body.

wheels. Wheelbase is 118 inches; tires, 44 by three inches in front, and 52 by three in rear. In other respects it is similar to the larger machine.

The lumber truck is designed to fulfill the particular

Digitized by Google

requirements of this industry. It is equipped with a patented roller bed device by means of which an entire load may be taken on or unloaded in a few minutes, without disturbing the piling. A hand operated winch moves the rollers so that the work may be accomplished easily by one man.

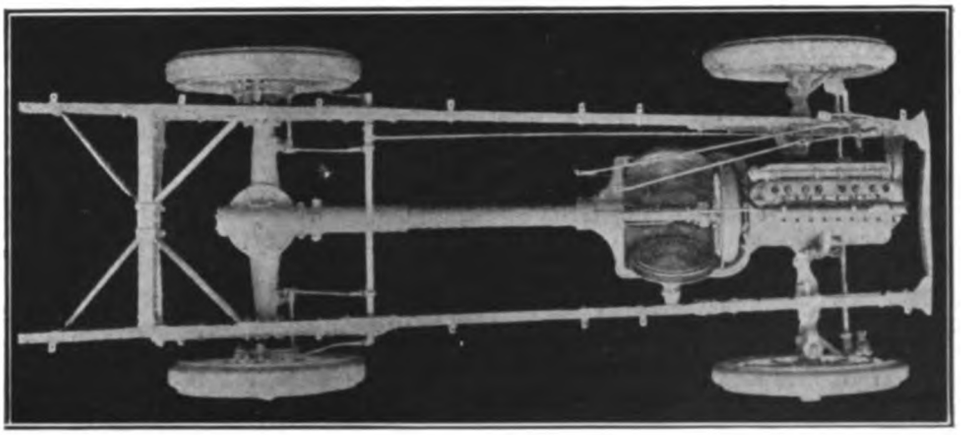
Chassis of the One-Ton Natco Wagon, Presenting the Relation of the Parts.

Monitor.

The Monitor Automobile Works, Janesville, Wis., displayed two two-cylinder Monitor vehicles and two chassis, all of 1500 pounds capacity. The motor is located under the floor with driver and single control lever at the right. The cylinders are opposed with bore of five inches and stroke of four. Cooling is by water, thermo-syphon system, with cellular radiator. Ignition is by Remy magneto and dry cells. Lubrication is by mechanical oiler. Clutch is a cone. Transmission is planetary, two speeds forward and reverse. Drive is by shaft. Brakes are internal and external on rear wheels. Springs are semi-elliptic in front and full elliptic in rear. Wheelbase is 100 inches; tread, 56 inches; tires, 33 by 2.5 inches in front and 34 by three in rear. Chassis weight is 2200 pounds.

Natco.

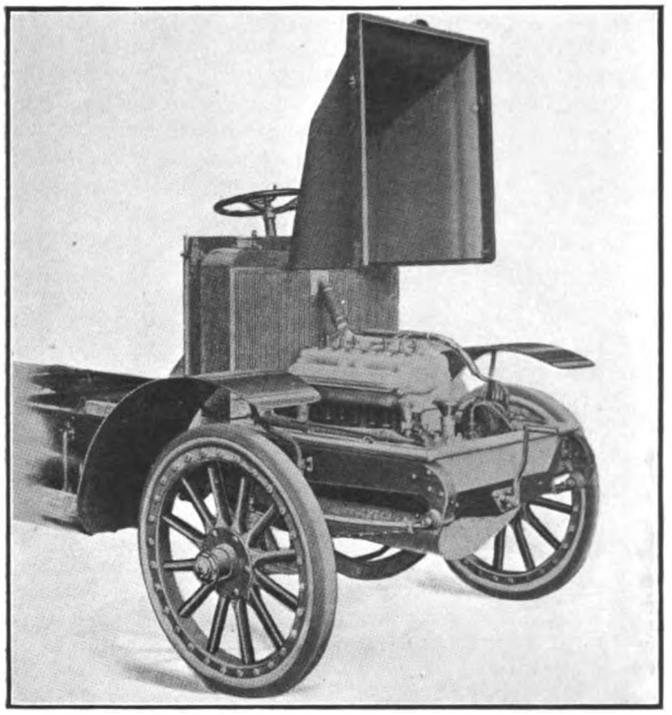
The National Motor Truck Company, Bay City, Mich., now calls its product the Natco, and was represented by one four-cylinder truck and a chassis, both of one-ton capacity. The motor is under a hood and driver at the left with central control levers. Cylinders are cast en bloc with bore of 3.5 inches and stroke of five. Cooling is by water, thermo-syphon system, with vertical tube radiator. Ignition is by high-tension magneto. Lubrication is by force feed. Clutch is a leather faced cone, supported by compression springs. Brakes are double, internal set in rear hubs. Springs are semi-elliptic, front and rear. Wheelbase is 104 inches; tread, 56; tires, 36 by 3.5, front and rear. Chassis weight is 2400 pounds.



The motor is supported on a sub-frame and is so located that the driver's seat is brought up to the rear of the hood, which is very short, giving the appearance of a motor-under-the-floor location. When the bonnet is raised, the entire mechanism is exposed. The jackshaft is of the full floating type, the housing being attached to the underside of the frame. Final drive is by double side chains, which are encased and run in an oil bath. An auxiliary spring is carried under a double cross member in the rear, this converging at the centre and supplying an additional brace.

A particular feature is the method of lubrication, in which the oil is filtered through water. The main reservoir of six quarts capacity is attached to the bottom of the engine case, and the pumps, which are gear driven by camshaft, are located in a compartment at the forward end of the motor. The oil is forced from the pumps to the end bearings, through the crankshaft to the connecting rod pins. The excess returns to the main supply tank through the standpipe, which extends to within .375 inch of the bottom of the water compartment, and owing to the difference in specific gravity between water and oil, the latter rises to the top of the water and overflows into the main reservoir. During the passage of the lubricant through the water, carbon which is collected by the oil while performing its lubricating function, is precipitated to the bottom of the water compartment, which can be cleansed thoroughly at certain intervals. In addition to the clarifying of the oil, it also is cooled. Lubricant in the forward pipe line flows through the sight feed on the dash.

Old Reliable.



The Henry Lee Power Company, Chicago, showed one four-cylinder Old Reliable 3.5-ton truck and chassis of the same capacity. The motor is located under the floor, with driver and levers at the right. Cylinders have a bore of 4.75 inches and stroke of 5.5. Cooling is by water. Ignition is by a double system. Lubrication is by a self-contained system. Clutch is a multiple disc. Transmission is selective.

Although rated at 3.5 tons, it is said that five tons have been handled on this vehicle with satisfactory results. The motor is carried on a sub-frame, and so arranged that it may be accessible readily by the removal of the radiator, which is supported on trunnions, and the bolted bumper cross member. In addition to the support given the transmission through the jackshaft housing, the forward end of the transmission case is bolted to a heavy cross member that is securely braced with gussets. Back of the jackshaft and immediately over the rear axle is another cross member. The special features claimed for the truck are its complete accessibility and its sturdy construction throughout for both the chassis and the bodies.

Great Dane One-Ton Chassis, Employing Novel Friction Transmission and So-Called Perfect Three Point Suspension.

Digitized by Google

Indicating Accessibility of Adams Power Plant, and Foreign Radiator Mounting.

Philadelphia.

The Philadelphia Truck Company, Philadelphia, showed one four-cylinder 1500-pound wagon. The motor is located under the floor with driver at the left and central control levers. Cylinders are cast in pairs with bore of 3.625 inches and stroke of 4.25. Cooling is by water, with centrifugal pump and honeycomb radiator. Ignition is by storage battery. Lubrication is by force feed. Clutch is a dry disc, Raybestos faced. Transmission is selective, three speeds forward and reverse. Drive is by shaft. Two sets of brakes are fitted, both internal expanding. Springs are semi-elliptic in front and three-quarter elliptic in rear. Wheelbase is 112 inches; tread, 56; tires, 34 by four, all around. Chassis weight is 2100 pounds.

The motor is a new model of the Peru line, seen for the first time at the pleasure car show in Chicago. It is supported at three points on the main frame, and is of unit construction, including an E. E. electric self-starter as an integral part. This means that the combined motor-generator of the starting system takes the usual place of the flywheel, the functions of the latter being performed by the field of the generator.

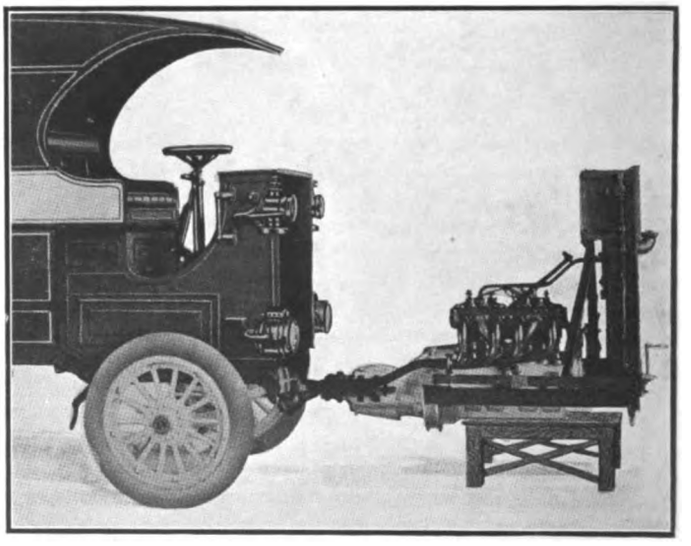
Premier.

The Premier Motor Manufacturing Company, Indianapolis, Ind., well known as maker of the Premier pleasure line, displayed its new Premier truck of 1.5 tons capacity. The motor is the same as that employed on the "4-40" cars, but the construction of the chassis frame has been materially strengthened throughout. This is particularly true of the rear axle, although it is of the same design as that of the pleasure cars. Dual pneumatic tires were shown, but solids are offered as an option. Semi-elliptic springs, front and rear, replace the three-quarter elliptic members of the pleasure line.

Sandusky.

The Sandusky Auto Parts & Motor Truck Company, Sandusky, O., presented two four-cylinder 1.5-ton vehicles. The motor is located under the floor with driver and levers at the left. Cylinders are cast en bloc with bore of 3.75 inches and stroke of five. Cooling is by water, with centrifugal pump and vertical tube radiator. Ignition is by Mea magneto. Lubrication is by the constant level splash system. Clutch is a cone. Transmission is selective, three speeds forward and reverse. Brakes are double expanding, both in rear hubs. Springs are semi-elliptic in front and three-quarter platform in rear. Wheelbase is 106 inches; tread, 56; tires, 40 by 3.5 inches solid or 36 by five pneumatic, front and rear.

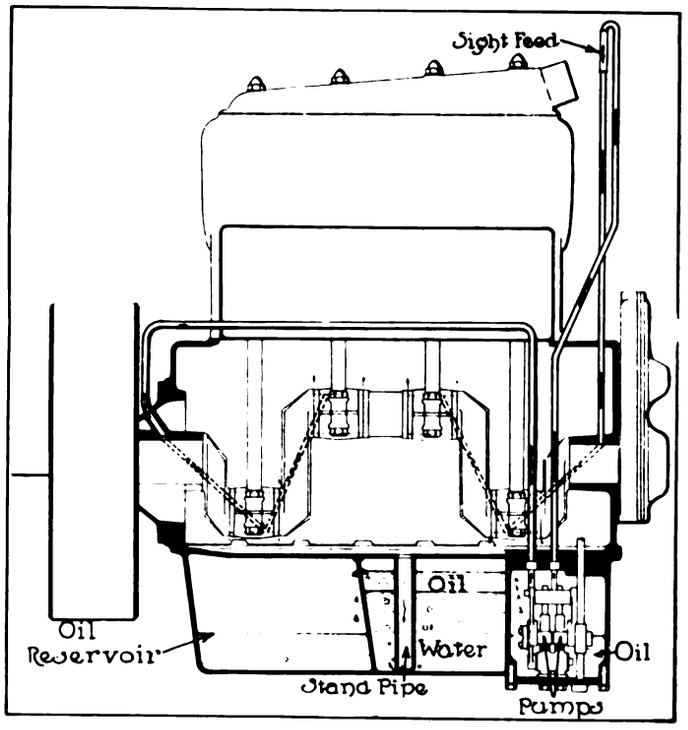
Accessibility of the power plant is afforded by mounting on a sub-frame, which can be withdrawn bodily from the chassis. The removal is accomplished by simply withdrawing six spring controlled plungers, raising the steering column and operating two levers that release the sub-frame and drop it down onto rollers. The assembly then may be withdrawn much the same as pulling out a drawer. The radiator and fuel tank are connected to the power plant in such manner that the removal may be made without breaking water, fuel or electric connections.



Schmidt.

The Schmidt Bros. Company, Chicago, showed two two-cylinder vehicles of half-ton and one-ton capacity and a chassis. The motor is located amidships and the driver at the right. The single lever for high speed is attached to the steering post, leaving the front of the car remarkably free. Cylinders are opposed. Cooling is by air. Ignition is by magneto. Lubrication is by force feed and splash. Transmission is planetary, two speeds forward and reverse. Drive is by roller chain. Brakes are internal expanding. Springs are quarter-elliptic in front and coil in rear. Wheelbase is 92 inches, and tires, 38 by 2.5 inches on the one-ton model, and 80 inches and 38 by two inches, respectively, on the half-ton.

Service.



The Service Motor Car Company, Wabash, Ind., presented one four-cylinder one-ton Service wagon and a chassis. The cylinders have a bore of 3.75 inches and stroke of 5.25. Cooling is by water. Ignition is by magneto. Transmission is friction. Drive is by chain. Springs are semi-elliptic all around. Large, solid tires are fitted.

It may be stated that the chief feature of the Service line is the double friction disc transmission scheme, in which this unit is supported by an overhead yoke, and two cross members support the bearings of the driven discs. The shifting device is attached to the overhead yoke, with a long rod reaching to the operating lever beside the driver. The two driven discs are operated by means of a pedal and are held against the driven discs by heavy springs, and a tightener in case the load pull exceeds the holding ability of the springs.

Illustrating Method of Removing Power Plant, Radiator and Fuel Tank on Sandusky Truck.

Lubrication System Employed on Nuteo Vehicles, by Which Oil Is Clarified and Cooled.

Another novelty in connection with the exhibit was the fitting of a pulley at the back of the frame, to which a belt may be applied for use in driving agricultural implements, etc. This is operated by means of a shaft from the back driving pulley, and is supported by means of bearings attached to the frame at the back.

Smith.

The A. O. Smith Company, Milwaukee, Wis., displayed one four-cylinder five-ton Smith truck. The motor is located in front under a hood with driver and levers at the right. The cylinders have a bore of 4.5 inches and stroke of 5.5. Cooling is by water. Ignition is by Bosch magneto. Clutch is a cone. Transmission is the Cotta system, with gears always in mesh. Drive is by worm.

There is very little about this vehicle that is conventional in design. The frame is of seven-inch section, pressed with a beaded channel and concave surface. The cross members are of the overhead yoke type, serving also to carry the spring hangers. Even the seats are of steel, as are also the dash and all other parts.

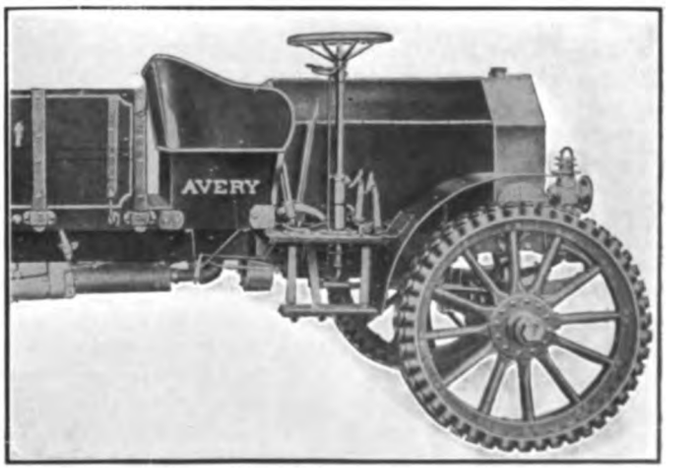
The transmission and rear system are a unit, and are so designed that there is absolutely a straight line to the worm drive. The transmission housing has an enlargement at the forward end, designed to be bolted to the ball and socket joint attached to the cross member. On the top is a lifting ring, and the construction is such that the entire transmission may be removed without disturbing a single gear.

The drive shaft extends through the large torsion tube and is connected to the worm, which is of the Lanchester design. The latter is so mounted that it may be removed by taking out the rear flange bolt, thus permitting the displacement of the entire housing.

Staver.

The Staver Carriage Company, Chicago, presented one four-cylinder ambulance. As is well known, this company has been producing pleasure cars for some years, and the vehicle displayed does not depart greatly from the design of these, except in the heavier construction. The same 40 horsepower motor is employed, and the body is fitted with all the modern appliances in connection with the work it is designed to perform.

Stegeman.



The Stegeman Motor Car Company, Milwaukee, Wis., displayed two four-cylinder Stegeman vehicles and a chassis. The motor is located in front under a hood, and driver at the left with central control levers. Two models were shown, the two and the six-ton. Cylinders have a bore of 4.125 inches and stroke of 5.25 in the former, and 4.5 by 5.5 in the latter. Cooling is by water, with centrifugal pump and vertical flat tube radiator. Ignition is by automatically timed magneto. Lubrication is by force feed and splash. Clutch is a multiple disc, dry plate. Transmission is selective, three speeds forward and reverse. Service brake is external contracting on propeller shaft; emergency internal expanding on rear wheels. Springs are semi-elliptic, front and rear. Wheelbase is 125 inches on the smaller and 145 on the larger. Tread is 60 and 78, respectively. Tires on the two-ton model are 34 by four in front and 36 by three, dual, in the rear. On the larger, these members are 36 by six in front, and 40 by six, dual, in rear. Chassis weight is 4000 pounds for the smaller and 7000 pounds for the larger.

Sternberg.

The Sternberg Manufacturing Company, Milwaukee, Wis., showed one four-cylinder four-ton chassis. Cylinders are cast in pairs, with bore of five inches and stroke of 6.5. Cooling is by water, with gear pump and flat tube radiator. Ignition is by Eisemann magneto and storage battery. Lubrication is by self-contained oiling system. Clutch is a Hele-Shaw. Transmission is selective, three speeds forward and reverse. Drive is by chains. Brakes are on jackshafts and rear wheels. Springs are semi-elliptic all around, with auxiliary spring in the rear. Wheelbase is 144 inches; tread, 70; tires, 36 by five, single in front and dual, rear. Chassis weight is 7000 pounds.

United States.

The United States Motor Truck Company, Cincinnati, O., displayed a four-cylinder, four-ton truck and chassis. Cylinders are cast in pairs, with bore of 4.5 inches and stroke of 5.5. Cooling is by water, with centrifugal pump and vertical tube radiator. Ignition is by Bosch dual magneto. Lubrication is by gear pump. Clutch is an internal cone. Transmission is selective, three speeds forward and reverse. Drive is by side chains. Brakes are on jackshaft and rear wheels. Springs are semi-elliptic front and rear, with auxiliary cross springs in the rear. Wheelbase is 114 inches; tread, 62 inches in front, 64 in rear; tires, 34 by five inches in front, 36 by five, dual, in rear. Chassis weight is 5800 pounds.

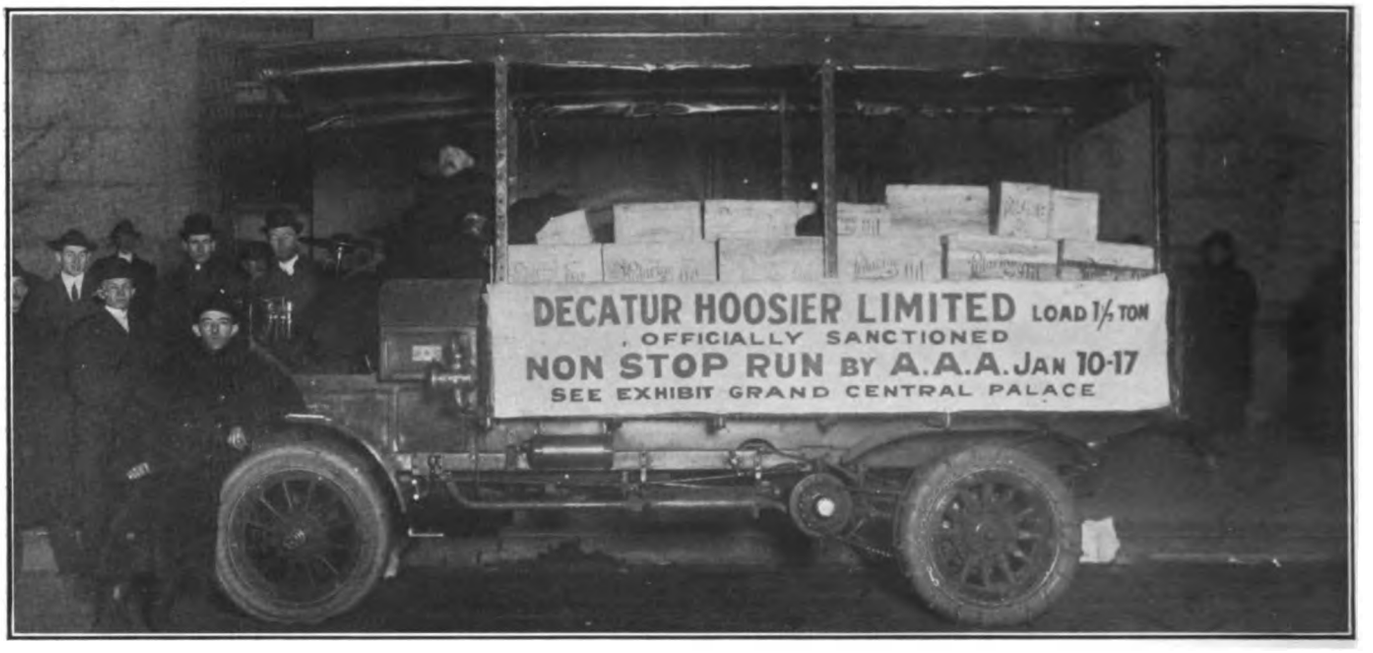
Utility.

The Stephenson Motor Car Company, Milwaukee, Wis., control of which is said to have passed to the J. I. Case Threshing Machine Company, Racine, Wis., presented its four-cylinder one and three-ton trucks, now known under the name of Utility. The motor is under the floor, and driver at the right with the levers in the centre. Cylinders are cast in pairs, with bore of 4.75 inches and stroke of five inches on the smaller vehicle and 4.25-inch bore and five-inch stroke on the larger. Cooling is by water, with centrifugal pump and vertical tube radiator. Ignition is by Eisemann magneto. Lubrication is self-contained within the crankcase. Transmission is double friction. Drive is by double chain. Brakes are expanding members. Springs are semi-elliptic in front and three-quarter platform in rear. Wheelbase is 134 inches; tread, 60; tires, 42 by five inches, all around.

The friction transmission is distinctive, being of the Stephenson design. A long propeller shaft connects the motor and one driving disc, the latter being supported on a cross member. The other driving disc also is supported by a cross member, and the driven discs are carried on a jackshaft, which in turn carries the sprockets transmitting the power to the rear wheels by chains.

Whitesides.

The Whitesides Commercial Car Company, New Castle, Ind., displayed one four-cylinder 1500-pound truck. The motor is in front under a hood with driver and levers at the right. Cylinders are cast en bloc, with bore of 4.125 inches and stroke of 4.5. Cooling is by water, thermo-syphon system. Ignition is by Splitdorf magneto and dry cells. Lubrication is self-contained. Transmission is planetary, two speeds forward and reverse. Drive is by double side chains. Brakes are internal expanding on rear wheel hubs. Springs are full elliptic, front and rear. Wheelbase is 118 inches; tires, 34 by 2.5 inches.



A feature of the construction is the use of kiln dried white oak, reinforced by steel armor for the frame. These members are held in place with heavy wood screws, frequently placed and staggered. The cross members also are armored wood, held in place by means of iron gusset plates. These latter are not right angle braces, but extend across the corners.

Wilcox.

The H. E. Wilcox Motor Car Company, Minneapolis, Minn., showed one four-cylinder three-ton truck and a chassis. The motor is in the cab, with driver and levers at the right. Cylinders are cast in pairs, with bore of 4.25 inches and stroke of 4.5. Cooling is by water. Ignition is by Bosch high-tension magneto. Lubrication is by gear driven pump. Clutch is a cone. Transmission is selective, three speeds forward and reverse. Drive is by side chains. Two sets of brakes are fitted, service on the jackshaft and emergency on the rear wheels, both internal expanding. Springs are full elliptic in front and three-quarter platform in rear. Wheelbase is 126 inches; tread, 62; tires, 36 by four inches in front, 36 by 3.5, dual, rear. Chassis weight is 5500 pounds.

DECATUR TRUCK IN SEVERE TEST.

To demonstrate the practicability of the commercial automobile a 1.5-ton Decatur truck, made by the Decatur Motor Car Company of Decatur, Ind., recently participated in a seven-day non-stop run. The event was sanctioned by the American Automobile Association and official observers accompanied the machine. The headquarters for the car was at the Flatow Flinn Company's service depot, 147 West 37th street, New York City, distributor for the Decatur product.

Decatur 1.5-Ton Mechanical Transport Which Participated in a Non-Stop Run Recently, and Which Carried a Consignment of Polarine Oil from Boston to New York.

The power wagon carried a maximum load of Polarine oil during its trial and the trips consisted of routes leading out of New York, including runs into Connecticut territory. Previous to the trials the truck was driven from Boston to New York City carrying a load of Polarine oil consigned to the Standard Oil Company of the latter city. During the test snow storms and extreme cold weather were encountered.

The use of the electric commercial vehicle is growing in favor in Boston and sales are reported weekly. Among those recorded recently was a five-ton coal truck to the Metropolitan Coal Company and a 3.5-ton General Vehicle, made by the General Vehicle Company, Long Island City, N. Y., to the New England Confectionery Company.

BOSTON'S MAMMOTH MOTOR TRUCK SHOW.

Exhibition Will Be the Largest Ever Held Under One Roof in America and Its Displays Will Be the Most Complete and Satisfactory of the Year.

THE first exclusive show of service wagons to be held in Boston will be opened in Mechanics' Building, Huntington avenue, the evening of March 13 and will be concluded the evening of March 20, this giving the same length of time for this exhibition that has been devoted to the display of pleasure vehicles in previous years. This policy is in keeping with those of the managements of the shows at New York and Chicago, where the industrial wagons were shown separately from those devoted to pleasure and professional use.

This will be the first exhibition at Boston where the displays will be divided, although for six years there has been a division given over to showing of vehicles created for industrial use. In previous years the wagons and trucks have been subordinated to the pleasure machines and have been located in the basement where they could not possibly receive the attention directed toward the more prominent exhibits on the first floor.

No criticism can be made of the policy of previous years because until within a matter of 18 months there was little realization of the possibilities of the service wagon market, and a year ago the conditions were such that a division of the two classes of exhibits could not well be made. The show will be made by the Boston Commercial Motor Vehicle Association, under the direction of Chester I. Campbell, and while it will be practically a continuation of the exposition of the Boston Automobile Dealers' Association, it will have separate existence.

Officials of the Boston Commercial Motor Vehicle Association.

The possibilities for business in this show are fully realized by the members of the organization conducting it, and it may be said that, as has been the experience with Boston exhibitions, it will be the largest and most productive of the national expositions of the year. There is every reason why this result should obtain. The eastern market is the richest of the world. This has been amply proven in the utilization of the pleasure car and with the power wagon. The conditions are unlike those existing elsewhere and there are innumerable influences that impel the use of the truck or wagon in every phase of industry and commerce.

Considered from every viewpoint the market is superior to all others. The best demonstration of this is the history of the automobile trade. The people have the motor knowledge that is essential to successful utilization of the power wagon in business. It is not necessary to engage in educational campaigns or missionary work to establish the value of the power vehicle as compared with existing methods of transportation. The reliability and endurance of the service wagon is acknowledged and with a majority of the people, at least, the principal question to be determined is the manner of adapting the machines to the methods the vogue, or changing the systems for haulage, both receiving and delivering to the better utilization of mechanical transports.

Why the automobile wagon has decided advantages need not be discussed. First of all there are more commercial centres than in any other section of the country, some of them comparatively short distances apart, each of which draws to it business of material proportions. No one municipality monopolizes the trade. The many lines of communication preclude this. There are the finest systems of highways in America with main thoroughfares generally connecting these cities and towns, by which delivery may be made at long distances. These roads mean quicker and more economical delivery than is possible in other parts of the nation. They mean the longer endurance of the vehicle and the minimum of operating expense. They mean the expansion of business of the individual, firm or corporation proportionate to the facilities for delivery, and while a maximum of 20 miles daily for a horse would mean a radius of less than 10 miles, the truck or wagon may be driven several times this distance in less time and haul a load several times larger.

Digitized by Google

There is no uncertainty as to the work that may be accomplished by the service wagon. There is no doubt as to its practical utility, and the main question is how shall the method of doing the work now done be changed so that it may bring either of two results—the lessening of the expense for what is now accomplished, or so increasing the field for business that it may be materially developed. It is not to be expected that the first may be so planned that it cannot be improved upon, and the second cannot be realized immediately; there must be creation of the demand through the purchasing advantages offered to the people.

There are differing elements entering into the market that must also be considered by those who are selling service wagons. One of these is the character of competition to be met with, but it is evident that where the largest volume of business may be obtained there are those who are striving to secure whatever proportion of it their vehicles will specially serve. Where there is no business there is no activity and no rivalry among the distributors, if there be even representation.

In the cities of proportions, where the business interests are large, the service wagon has been adopted in surprising numbers. This does not mean by large enterprises only, but by every interest that may be named, employing from the smallest to the largest vehicles and using them for equally varying work. Those who have turned to the newer method of haulage have found that business has followed the expedition of delivery. Economy of time to the purchaser is quite as necessary as to the seller, and the value of purchasing where goods are stocked and can be sent out without delay is apparent.

There is no longer need for the business man to fear complications from the possible failure of a service wagon. Every endeavor has been directed toward producing what is reliable and will endure, and the representatives have also made provision for supplying whatever may be needed for restoration and replacement in the event of wear. Some of the manufacturers have even gone further and provided their own service stations for the express purpose of maintaining the vehicles they build, and some of these are fitted so as to give every attention that could be found in a garage as well as the expert attention that is expected from those who specialize care and upkeep of the machines they sell. These are extremely large in some instances, the structures built purposely for the requirements of such service, and with equipment and facilities to do everything that might be desired. In fact some of these establishments are even more than factories, because they combine every de-

Mechanics' Building, Where the Boston Motor Truck Show Will Take Place.

Digitized by Google

partment of a factory as well as the accommodations and the service of the garage.

These conditions make apparent to the man who is considering the adoption of the service wagon that he will have to deal with entirely different situations than did those who first began mechanical haulage, and that he will not have to work out results blindly, for he has available the experience of those who have given the subject the closest study and have dealt with it from every angle and aspect. The market was never so promising, because there are innumerable reasons why the saving in handling of material or commodities is decidedly economical. Where it is practical to do so the motor truck or wagon has been used instead of the railroad for short hauls, this being due to obvious economy as well as the saving of time, besides the elimination of the possibility of damage.

Considering the Boston exhibition as it has been thus far arranged for: It will be fully as large as both the metropolitan shows, so far as number of makes of cars displayed is concerned, and it will closely approach, if not equal, the Chicago show. There is a total exhibition area in Mechanics' Building of 105,000 square feet, all of which has been given over to the displays of trucks, wagons, accessories and supplies. The decorations as arranged for the pleasure car exhibition will not be removed and the machines will be shown in one of the most pleasing settings created this season. As striking as were the other national expositions it is declared by Manager Campbell that the Boston show will be superior to them all in point of attractiveness.

Chester I. Campbell, Manager Boston Automobile Show.

The list of service wagon exhibitors has not been revised and it is expected that it will be considerably augmented before the opening of the show. As the facts are now known there will be a total of 61 different makes of service vehicles, which will be displayed generally by the local representatives or the branches of the makers. It is probable that this number will be increased to 70 at least. The proportions of the show may be the better understood when it is known that at Madison Square Garden in January, 37 different makes were shown, and at Grand Central Palace 33 different makes, making a total of 70 for both. At the Chicago exposition 82 different productions were on display. In 1911 there were 35 makes shown at Madison Square Garden and 57 were seen at Chicago. Taking the figures as stated it will be seen that Boston will have an exhibition that will far exceed all others save that at Chicago last month, and there is a prospect it will equal that.

In considering the known exhibitors it will be found that of the 61, 22 manufacture both pleasure cars and service wagons, while 39 are engaged exclusively in production of the commercial type. Last year 20 makes were of the first named category and 21 of the second. Of the exhibitors of 1911, 13 will make no display at Boston this season, and of these five manufacture service wagons exclusively and the remaining eight produce both types of vehicle.

Of the exhibitors who will be seen this year, 28 made exhibition a year ago and there will be 33 who did not show machines in 1911, which is a sufficient indication of what will be new to Bostonians and the thousands of visitors who will visit the big exhibition. So far as the show is concerned there will be, exclusive of the makes seen in 1911, 33 different makes of vehicles which, while possibly not unknown, will be decidedly interesting to all. There will be unusual opportunity for the examination and comparison of the different exhibits, while there will be display and demonstration of the body equipment that has been developed during the past year to meet the demands of the different owners.

As there is much dependent upon the special form of body installations that can be made, and a material factor in truck service is the special or general work that can be done by it, there will be a degree of attention directed toward the bodies that will equal that given to the chassis. While some of the machines have been shown at other large exhibitions they will be in every way new to Boston, and their advantages will be expatiated by those who will have them in change.

It is needless to specify that the show will introduce some features that are distinctly new. These will be found in the chassis, the bodies, and in the equipment installed upon them. It is probable there will be much to interest in the application of self-starting devices, although these have not as yet been given serious consideration by any large percentage of the manufacturers of service wagons. There is quite as much demand, however, for the installation of starters as with the pleasure machines. Besides this there will be distinct progression manifested in the details of construction as compared with the show of a year since. Many of these have been written of and described, but they will assuredly be interesting to those who have taken up the study of the problem of vehicular transportation.

In connection with the show there will be a number of demonstrations made for the purpose of establishing facts for the special benefit of those who will visit the exhibition. These will vary decidedly and it is not improbable that some will be made with a view of showing more than one capacity or quality. Naturally they will be given as much prominence as is consistent with the undertakings. There will not be so much attention to "stunts" as to practical utilizations, which will serve to inform and guide those making investigation or inquiry.

One of the best indications of the concern in the service wagon and the possibilities through its use is that there will be visits made the show by organizations of commercial character, especially for the purpose of learning systematically from those regarded as authorities facts that have material bearing. For instance, the New England Coal Dealers' Association, a body that has a membership of something like 1500 men, will visit the exhibition, this being the result of the association taking up the subject of transportation.

Undoubtedly this opportunity for the representatives of the manufacturers coming into contact with so many business men cannot be otherwise than mutually beneficial. Obviously it has been the very satisfactory result from practical service that has created this interest.

The exhibition of accessories and supplies will be largely continued through the power wagon show. While it is true that primarily many of the articles have been created and produced for pleasure car equipment and use, it is also a fact that these may be used in many instances with service wagons, and with interest of the visitors to the truck exhibition often directed toward two types of vehicle instead of one there is abundant reason to expect these will receive a deal of attention.

The following is the list of exhibitors, which is subject to revision, there doubtless being additions at opening time.

CLASSIFIED EXHIBITORS AT BOSTON AUTOMOBILE SHOW.

GASOLINE COMMERCIAL CARS.

(Second Week.)

110-111 Alco—American Locomotive Company, 591 Boylston street, Boston.

132-133 Atterbury—Atterbury Motor Truck Company, Buffalo, N. Y.

34-37 Autocar — Autocar Company, 642 Beacon street, Boston.

251 Bessemer — Bessemer Motor Truck Company, Grove City, Penn.

38 Buick—Buick Motor Company, Motor Mart, Boston.

148 Cameron — Standard Motor Truck Company, 9 Harcourt street, Boston.

339, 346 Chase—Chase Motor Truck Company, Syracuse, N. Y.

141 Clark—Edward S. Clark, 242 Freeport street, Dorchester, Mass.

222-224 Commer—Dodge Motor Vehicle Company, Lansdowne street, Cambridge, Mass.

149 Commerce — Curtis - Hawkins Company, 162 Columbus avenue, Boston.

17 Dayton—Whitten-Gilmore Company, 907 Boylston street, Boston.

102-103 Decatur—Decatur Motor Car Company, 20 Green street, Cambridge, Mass.

134, 150 De Dion—Boston Motor Company, 1002 Boylston street, Boston.

10 Eckhart—Eckhart Motor Truck Company, 116 Milk street, Boston.

13 Federal — Whitten - Gilmore Company, 907 Boylston street, Boston.

124 Ford—Ford Motor Company, 147 Columbus avenue, Boston.

26-27 Garford — Garford Company, Elyria, O.

105-109 G. M. C.—General Motors Truck Co., 944 Massachusetts avenue, Boston, and Butler Motor Truck Company, 1022 Commonwealth avenue, Boston.

226-227 Grabowsky—Lewis S. McCreary, 183 Pleasant street, Boston.

15 Gramm—Whitney-Barney Company, 823 Boylston street, Boston.

114 International — International Harvester Company of America, 43 Somerville avenue, Somerville, Mass.

100-101 Kelly—Eastern Motor Truck Company, Shoe & Leather building, Cambridge, Mass.

129-130 KisselKar—KisselKar New England Branch, Motor Mart, Boston.

8, 12 Knox—Underhill Company, 885 Boylston street, Boston.

151-152 Koehler—L. E. Schlotterback Manufacturing Company, East Orange, N. J.

135 Lauth-Juergens — Lauth-Juergens Motor Car Company, Lima, O.

15 Lippard - Stewart — Whitney-Barney Company, 823 Boylston street, Boston.

5 Locomobile—Locomobile Company of America, 700 Commonwealth avenue, Boston.

19 Lozier—Lozier Motor Company, 646 Beacon street, Boston.

228-235 Mack—Mack Motor Truck Company, 201 Pleasant street, Boston.

329-330 Mais—R. L. & H. H. Smith, 1008 Commonwealth avenue, Boston.

147 McIntyre — Standard Motor Truck Company, 9 Harcourt street, Boston.

32 Mercury—Mercury Manufacturing Company, Chicago, Ill.

21 Morgan—Morgan Motor Truck Company, Worcester, Mass.

24-25, 28-29 Motor Wagon—Boston Motor Wagon Company, Motor Mart, Boston.

1-2 Packard—Alvan T. Fuller, 1089 Commonwealth avenue, Boston.

14, 18 Peerless—Peerless Motor Car Company of New England, 660 Beacon street, Boston.

312-313 Philadelphia — Philadelphia Truck Company, Philadelphia.

16, 20 Pierce-Arrow—J. W. Maguire Company, 745 Boylston street, Boston.

318-320 Pope-Hartford—Dodge Motor Vehicle Company, Lansdowne street, Cambridge, Mass.

31 Poss — Poss Motor Company, Detroit.

118-120 Reo—Linscott Motor Company, 163 Columbus avenue, Boston.

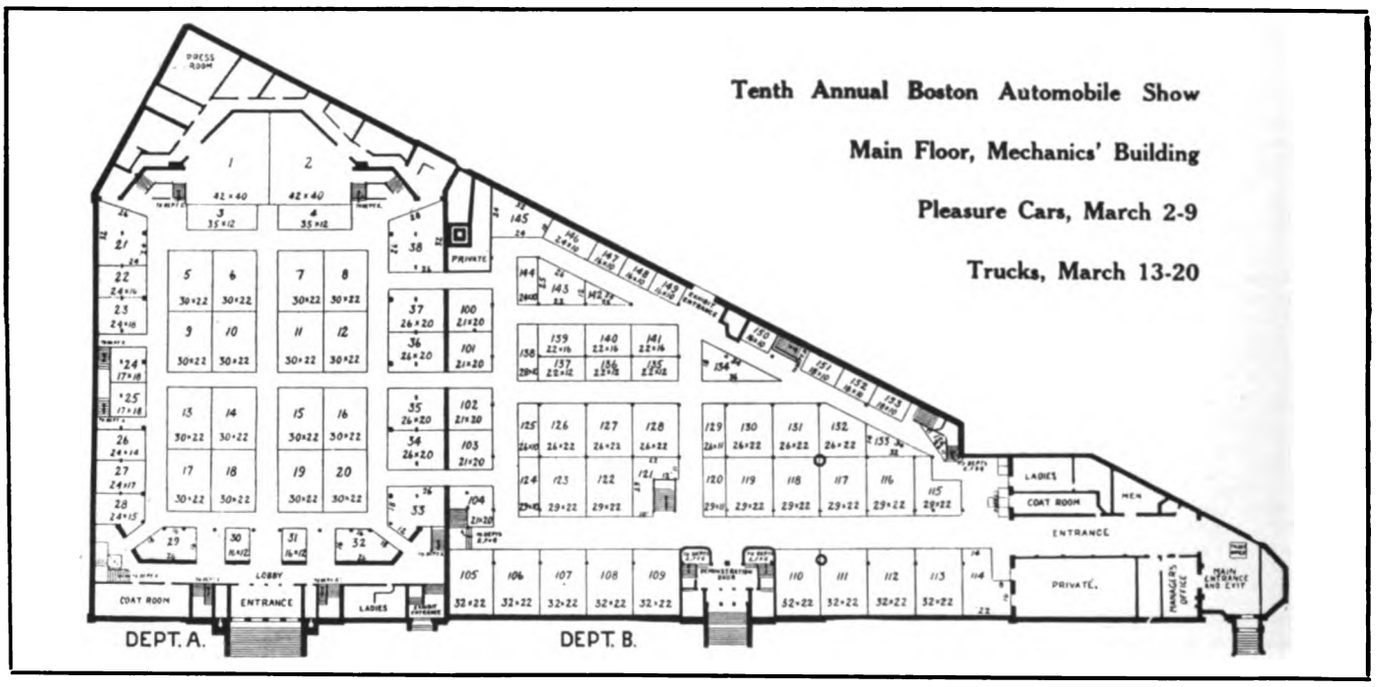
332-335 Sandusky — Sandusky Auto Parts & Motor Truck Company, Sandusky, O.

22 Sanford—Sanford-Herbert Company, Syracuse, N. Y.

115-117 Sampson — United Motor Boston Company, 100 Massachusetts avenue, Boston.

254-256 Saurer—Mack Motor Truck Company, 201 Pleasant street, Boston.

142-144 Speedwell — Curtis-Hawkins Company, 162 Columbus avenue, Boston.



6 Stearns—J. H. MacAlman, 96 Massachusetts avenue, Boston.

237 Sternberg—Hanson Bros., 95 Commercial street, Boston.

112 Teel-Woodworth — Teel Manufacturing Company, Main street, Medford, Mass.

113 Universal — Universal Motor Truck Company, Detroit.

145-146 Velie—Velie Boston Branch, 92 Massachusetts avenue, Boston.

326-327 Victor—Victor Motor Car Company, 75 Haverhill street, Boston.

30 Westfield — Westfield Motor Truck Company, Westfield, Mass.

4, 7, 11 White—White Company, 320 Newbury street, Boston.

ELECTRIC COMMERCIAL CARS.

(Second Week.)

137-139 Baker—Frank N. Phelps, 17 Harvard street, Boston.

121 Couple-Gear—W. E. Eldridge, 178 Devonshire street, Boston.

136 Detroit—Anderson Electric Car Company, Detroit.

122-123 General Vehicle — General Vehicle Company, 84 State street, Boston.

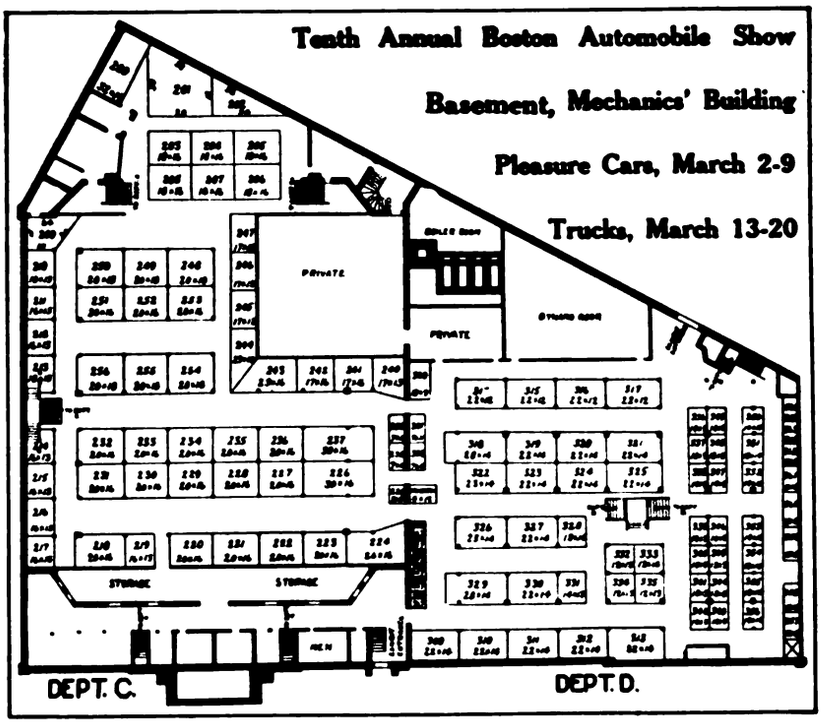
105-109 G. M. C.—General Motors Truck Company, 944 Massachusetts avenue, Boston.

127 Lansden — Lansden Company, Newark, N. J.

126 Walker—Walker Vehicle Company, 131 State street, Boston.

Digitized by Google

STEAM COMMERCIAL CARS.
(Second Week.)



23 **Stanley** — Stanley Motor Carriage Company, Newton, Mass.

IGNITION EQUIPMENT.

614* **American Storage Battery Company**, Albro street, Cambridge, Mass., batteries.
514* **Apple Electric Company**, Dayton, O., batteries.
616-617* **Bi-Motor Equipment Company**, 177 Portland street, Boston, Salom batteries.
242* **G. C. Blickensderfer Company**, Stamford, Conn., spark plugs.
408-409* **Burn-Boston Battery & Manufacturing Company**, 9 Doane street, Boston, batteries.
414* **Champion Ignition Company**, Flint, Mich., magnetos, plugs.
504* **Connecticut Telephone & Electric Company**, Meriden, Conn., Connecticut magnetos, etc.
619* **Smalley Daniels**, Motor Mart, Boston, Kingston magnetos, etc.
415* **Detroit Electric Appliance Company**, Detroit, batteries.
500* **Edison Storage Battery Company**, 895 Boylston street, Boston, batteries.
546-547 **Electric Storage Battery Company**, Philadelphia, batteries.
620* **Walter J. Forbes**, 243 Columbus avenue, Boston, magnetos, plugs, etc.
531* **Heinze Electric Company**, Lowell, Mass., Heinze magnetos.
...* **Holt & Beebee**, 40 Sudbury street, Boston, electric supplies.
618 **Holtzer-Cabot Electric Company**, Brookline, Mass., magnetos, etc.
...* **C. S. Knowles**, 7 Arch street, Boston, spark plugs.
417* **W. H. Leland & Co.**, Worcester, Mass., coils, etc.
553* **Mac-Kae Manufacturing Company**, 185 Armory street, Jamaica Plain, Boston, Mac-Kae spark plugs.
508 **Marburg Bros., Inc.**, New York City, Mea magnetos.
441-442* **Chas. E. Miller**, 202-204 Columbus avenue, Boston, magnetos, plugs, etc.
435* **A. R. Mosler & Co.**, New York City, spark plugs.
336* **Narragansett Chemical Company**, Providence, R. I., batteries.
540* **National Carbon Company**, Cleveland, O., batteries.
509* **National Coil Company**, Lansing, Mich., National magnetos, etc.
421* **Pittsfield Spark Coil Company**, Dalton, Mass., Pittsfield magnetos, etc.
543 **Remy Electric Company**, Anderson, Ind., Remy magnetos, etc.
601* **T. F. Russell & Co.**, 176 Federal street, Boston, magnetos, etc.
548-549 **C. F. Splitdorf, Inc.**, Motor Mart, Boston, Splitdorf magnetos, etc.
521 **U. S. Light & Heating Company**, New York City, batteries.
509* **Vesta Accumulator Company**, Chicago, batteries.

TIRES, RIMS, ETC.

519-520 **Ajax-Grieb Rubber Company**, 15 Park square, Boston, Ajax tires.
516* **Allen Auto Specialty Company**, New York City, cases, pressure gauges, etc.
355 **Atlas Chain Company**, Brooklyn N. Y., chains.
513* **Auburn Auto Pump Company**, 537 Tremont street, Boston, pumps, compressors.
581* **Batavia Rubber Company**, Batavia, N. Y., Batavia tires.
429A* **Booth Demountable Rim Company**, Detroit, Booth rims.
610* **Boston Auto Gauge Company**, 8 Waltham street, Boston, gauges.
609* **Boston Tire & Rubber Company**, 182 Friend street, Boston, tires.

NEWS OF THE COMMERCIAL VEHICLE INDUSTRY.

Lanchester-Daimler Worm Drive to Be Produced in America---Pertinent Information Concerning Production and Selling---Truck Shows in Smaller Cities.

Coincident with the return of W. C. Baker, president and mechanical engineer of the American Ball Bearing Company, Cleveland, O., from an European trip comes the announcement that this concern has supplemented its present product by the addition of a complete line of worm driven axles, in which the imported type of Lanchester-Daimler worm and worm wheel will be utilized. In this connection, it is remembered that Mr. Baker designed and constructed the first bevel gear driven axle to be used in an automobile in this country. His adoption of the worm drive is expected to bring about as important consequences in the industry as his action with reference to the bevel gear at a time when its use was considered impossible.

Of course, the worm drive situation is by no means analogous to that of the bevel gear at the time mentioned. This system of final drive has been in successful use in America for more than a year, and the result of the recent shows indicates that it is to be employed even more generally in the future. Interest in worm construction is therefore decidedly keen just now.

The Lanchester type has been most thoroughly tried out under all sorts of conditions and is widely used by a number of prominent foreign truck manufacturers. It is the result of years of study and experimentation on the part of Mr. Lanchester of the Lanchester Motor Car Company, Coventry, England, and the Daimler and Lanchester companies, which have been using worm drive for the past 10 years, have adopted it exclusively on their entire output. It also has found recognition in such well known pleasure cars as the Minerva, Panhard and others.

The design is that commonly known as the enveloping or hour glass type. However, it is distinct from all others in use today, because of the fact that Mr. Lanchester has been able to perfect special machinery and cutters which are claimed to eliminate all hand finishing operations and to leave the worm and gear absolutely true as to tooth form.

"While abroad," says Mr. Baker, "I investigated the various other types of worms and gears in use, and was especially impressed with the Lanchester type. As the matter of properly mounting, so as to result in rigidly holding the worm and gear in the axle construction is of vital importance, this point received careful consideration. I was gratified to find that our own manufacturing practise would permit of the adaptation of the Lanchester worm in our axle construction without modification or changes. The two harmonize perfectly."

Mr. Baker was accompanied on his trip by Charles E. Davis, general manager of the Warner Gear Company, Muncie, Ind., and this concern has contracted with the Daimler company and Mr. Lanchester for the exclusive right to the Lanchester worm and worm wheel in the United States and Canada.

TO MAKE ELECTRIC DELIVERY WAGONS.

William E. Pratt of the Pratt Manufacturing Company, Joliet, Ill., has purchased the personal property of the Economy Motor Car Company of that city, and has submitted a bid for the real estate, which probably will be accepted. It is understood that Mr. Pratt will operate the plant for the production of electric vehicles of the light delivery and roadster types.

During the past year W. R. Everett, formerly president of the Economy company, has developed these electric vehicles, some of which have given excellent satisfaction in the hands of purchasers. Owing to unsettled matters regarding the plant, the new management has not made any definite statements, but it is known that the cars will be priced moderately.

DECATUR TRUCK GOING TO GRAND RAPIDS.

According to a dispatch from Decatur, Ind., a movement is on foot to remove the plant of the Decatur Motor Car Company, maker of Decatur "Hoosier Limited" trucks, from that city to Grand Rapids, Mich. This information indicates that Grand Rapids capitalists are prepared to invest $100,000 in the concern, providing this move is made.

PRODUCES ELECTRIC OMNIBUS.

The first vehicles produced by the Electric Omnibus Corporation of New York City, which was incorporated about six months ago, has been placed with Carson, Pirie, Scott & Co., Chicago. These vehicles are designed by C. J. Field, who has been identified prominently with electric railroad engineering for some years, and are equipped exclusively with the Edison battery. The plant is at Troy, N. Y.

The 'buses mentioned are four in number, each with seating capacity for 18 passengers and of the pay-as-you-enter type. The driver acts as conductor as well, and collects the fares. It follows that the entrance is at the front, and it may be added that the driver is completely enclosed.

Part of the batteries are placed under a small hood in front and the remainder are under the passengers' seats. The gearing provides a maximum speed of 12 miles an hour, and with short boosting charges at end of each day's run, a daily mileage of 80 is obtained. The motor is a General Electric 60-volt series wound, and drives direct through a cardan shaft to jackshaft, final drive being by chains.

The controller is operated by means of a lever on the steering column, and is thoroughly protected against short circuiting. Two independent braking systems are provided, service members acting on drums at the extremities of the jackshaft and emergency on the rear wheels. Tires are 34 by 3.5 inches, dual, in the rear, and 32 by 3.5, single, in front.

WORCESTER WANTS DART COMPANY.

The Board of Trade in Worcester, Mass., is taking active interest in an endeavor to secure the plant of the Dart Manufacturing Company, maker of Best commercial vehicles, now located at Waterloo, Ia. At a recent meeting, the directors definitely decided to invite the company to locate its Eastern factory in that city and to secure $100,000 of Worcester capital, which will be half of the $200,000 increase contemplated, making the total capitalization of the concern, $325,000.

It is understood that if the proposed factory is located in Worcester it will be considered the main plant and will offer employment to between 400 and 500 workmen at the outset. This is based upon the assertion that the company now has orders for 4000 cars to be delivered during 1912.

FORD MOTOR COMPANY TAKES IMPORTANT STEP.

The important bearing which the opening of the Panama canal will have upon American export business is beginning to be realized by the motor car industry. As a result, California and other Pacific Coast states undoubtedly will be included among the automobile manufacturing centres in the very near future. One of the first concerns to take this step is the Ford Motor Company of Detroit, which is seeking a site for a branch factory either at Los Angeles or San Francisco.

James Couzens, secretary-treasurer of the Ford company, has been on the coast during the past month, making arrangements for the new plant. It is understood that it will cost approximately $300,000 and will give employment to at least 800 workmen at the start. The construction and equipment will be modern in every particular, and the capacity will be about 5000 cars a year. As the Ford company manufactures both pleasure and commercial vehicles, both types will be constructed in the California plant.

The main building will be 500 by 500 feet, and will be of reinforced concrete construction throughout. Electric power will be employed to operate the machinery. Motors will be shipped to California from the plant on Long Island, and it is anticipated that the Panama canal will aid materially in the shipment of these. In addition, it is expected that the opening of that canal will mean a largely increased merchant marine, plying between the United States and the Far East, and the plans of the Ford company include the shipping of large consignments to Hawaii, Japan and the Asiatic Continent.

CHANGES PLANNED BY SMITH COMPANY.

According to a dispatch from Milwaukee, Wis., all shares of the A. O. Smith Company of that city, not at present held by those members of the concern actively engaged in the manufacture of automobile parts and forgings, will be purchased by persons intimately connected with the corporation. The stock affected by the transfer is valued at about $500,000, while the total capitalization of the company is $1,000,000.

It is announced that the change in stockholders, which has been contemplated for some time according to the dispatch, will be made in order to effect a more compact organization. No immediate changes in the extent or control of the corporation are in view, it is said, and the policy of the management will remain the same. The information is of interest in view of the recent announcement of a five-ton truck bearing the Smith name.

CANADA'S MILLION DOLLAR CONCERN.

The Gaselectric Motors, Ltd., St. Thomas, Ont., has been incorporated at Toronto with capital of $1,000,000. While the plans of the concern are still unannounced, it is understood that motor cars will be produced in which electricity will be generated by a gasoline engine on the car itself, the power being applied to the road wheels by separate motors located in the hubs.

NEW TAXIMETER PRESENTS RECEIPT.

Walter Lewin of San Francisco, Cal., has perfected the Lewin taximeter, which is to be placed in the market by the Pacific Taximeter Company, recently organized in that city. In addition to the usual functions of a device of this nature, the new product will present the customer with a receipt for the fare paid. In effect, it will keep its own books and eliminate the necessity for frequent inspection by the operating company.

The meter is built in two units, called the registering and duplicate ticket device, respectively. The registering portion is operated by a series of gears thrown into and out of mesh by the tariff lever, which is in turn coupled up and directly connected to the registering wheels. The duplicate ticket device is that portion of the meter which is mounted in the cover and can be removed from the instrument by unlocking a Yale lock.

There are two reels for the duplicate and original ticket, which roll over guide rollers parallel with the face of the registering wheels when in position, the duplicate ticket being rolled again on a drum and the original being discharged through a chute in the side of the meter. On the same cover the whole of the stamping device is mounted somewhat on the principle of a typewriter hammer, each character on the registering wheels having a separate hammer that imprints on the ticket.

SWETLAND HEADS COMMER DIRECTORATE.

H. M. Swetland, who is well known in the industry because of his connection with its publications, has resigned as president of the Class Journal Publishing Company, New York City, to become chairman of the board of directors of the Wyckoff, Church & Partridge, Inc., maker of Commer trucks in America, under license from Commercial Cars, Ltd., of England.

ADOPTS INTERNAL GEAR DRIVE.

Incorporated recently to manufacture a light delivery car to sell at a popular price, the General Industrial & Manufacturing Company, Indianapolis, Ind., announces the adoption of the internal gear drive. The model in which this will be employed is a 1500-pound wagon, designed for general use, which is expected to appeal to a large class of purchasers.

Among the advantages claimed for this type of drive are the complete enclosure of all working parts, carrying the load on a solid axle, and transmitting the power by an independent live axle. One of the most interesting examples of this type of car, is cited in the vehicles used on the Fifth avenue omnibus line in New York City, which have been in use for a long period. Others of a similar design have been in successful service in England and Germany. The German army has favored this type, and has many such vehicles in operation.

ANOTHER TRUCK CONCERN IN WISCONSIN.

Announcement is made of the incorporation of the Piggins Motor Truck Company, Racine, Wis., with capital of $125,000. This is not a new concern, in the strict sense of the word, and the product will not be entirely new, inasmuch as those who comprise the company have been engaged in the production of commercial cars in a small way for some time.

Early in the history of the industry, C. B. and F. H. Piggins of Racine started the manufacture of gasoline engines and specialties. Three years ago they became makers of trucks and pleasure cars, and several of these have been giving splendid satisfaction in service. The new plans call for enlarged factory and machine shops, so that the entire attention may be devoted to the production of commercial vehicles on a larger scale.

GENERAL MOTORS BEGINS EDUCATIONAL CAMPAIGN.

Gleeson Murphy, who is recognized as one of the most expert commercial vehicle salesmen in the country, has become vice president of the General Motors Truck Company, Detroit, and assistant to President Neal of the General Motors Company, which is the parent organization of the truck concern. Mr. Murphy has spent much time in investigating industrial transports in service and has a thorough knowledge of what should be expected from a vehicle of this type. Under his management the company will undertake a nation-wide educational campaign, in which the results of his investigations will be instilled into the minds of hundreds of business men throughout the country.

Briefly outlined, the particular reasons why business men should use motor trucks are set forth by Mr. Murphy as follows: Because they will increase the efficiency of the delivery system, give prestige, help increase business, enable a large territory to be covered in a given time, work every day in the year, and will not be affected by the elements, heat or cold. In addition, he contends that the efficiency of the entire organization is judged by the manner in which the business man is able to deliver goods.

Based upon the fact that previous to Jan. 1, 1912, $60,000,000 worth of trucks had been sold since the inception of the industry, Mr. Murphy suggests that business men should study the new method of transportation because they are able to get unbiased opinions from the manufacturers, and to make a thorough investigation of the relative merits of the gasoline and electric systems. He holds that the market affords a wide range of capacities and bodies both in the electric and gasoline types.

Gleeson Murphy, Vice President, General Motors Truck Company.

That the motor truck is a certainty, having reached a standardization that insures its every-day use, is another argument. It is applicable to nearly all lines of business. owing to the wide choice offered in the matter of body designs and mechanical equipment. Economy is taken care of in the suggestion that the motor truck takes the place of two or three teams, depending largely upon the routing and extent of the delivery system in question. As a final feature, it is noted that the mechanical conveyance will carry loads and negotiate hills impossible for horses to undertake.

NEW TRUCK FROM NORTH CAROLINA.

Another instance in which a well known manufacturer of wagons has been replaced by a new concern which will devote its attention to the production of motor trucks, comes from Charlotte, N. C. A few years ago the Wadsworth Wagon Works of that city, which had been engaged in the construction of wagons for many years, was succeeded by J. L. Owens & Son, which became interested in the automobile industry, through the manufacture of tops and upholstery, in addition to its large business of painting bodies, etc.

This latter concern now has been reorganized as the Owens Wagon & Automobile Works with capital of $50,000. It appears that its predecessor had been experimenting with the construction of commercial vehicles during the past year, and is ready to place in the market at least one model. The officers of the new concern are: President, J. L. Owens; vice president, Frank O. Owens; secretary and treasurer, Skinner S. Alston.

HEWITT WITH MACK AND SAURER.

The Hewitt Motor Truck Company, which was organized shortly before the New York show season began, has become amalgamated with the International Motor Company of New York City, which already was in control of the Mack Bros. Motor Car Company of Allentown, Penn., and the Saurer Motor Truck Company of Plainfield, N. J. Negotiations are said to be under way looking toward the purchase of at least one other concern, a prominent maker of electric vehicles, but no definite information has been vouchsafed by those interested.

It will be remembered that the Hewitt line is one of the oldest in the industry. Something over a year ago the Metzger Motor Car Company of Detroit purchased the original company, principally for the purpose of acquiring a Selden patent license. Hewitt trucks, ranging in capacity from 1500 pounds to 10 tons, have given excellent satisfaction in the hands of users since the first vehicles were placed in the market, and it caused little surprise when it was announced in December that the original people had formed a company under the old name to take charge of their production again.

It has been known for some time in the industry that the International Motor Company was anxious to increase its holdings, particularly in the matter of offering a wide variety of truck sizes. The rumored purchase of the Hewitt concern early in the month proved to be premature, but the official announcement was made Feb. 28. The new arrangement goes into effect March 1.

WAGON MAKER TO PRODUCE TRUCKS.

Although engaged in the production of wagons for a number of years, C. T. Woolson of Riverton, N. J., has been interested in the sale of automobiles for the past five years. Recently he was instrumental in the organization of the Woolson Auto Truck Company, which will produce a two-ton vehicle to sell at a moderate price. Announcement is made that the first truck of the Woolson design will be completed and on the road within 30 days.

WILL EXPLOIT ELASTIC WHEEL.

The American Elastic Wheel Company of 11 Broadway, New York City, has been organized for the purpose of exploiting the Feroci wheel, of Italian origin, although protected by American patents. It is claimed that a number of these wheels have been utilized on army trucks by the Italian government and that these have given excellent satisfaction. The device employs a series of rubber buffers and spiral steel springs. The officers of the concern are: President, Walter D. Ward; vice-president, Caesar Feroci, the inventor, and treasurer, Frank Ward.

SPLENDID INTEREST IN BALTIMORE'S TRUCK DISPLAY.

As an indication of the increasing interest being displayed in the use of commercial vehicles in Baltimore, it is remembered that but four makes of trucks were shown last year in connection with the local automobile show. This year the dealers of that city held a separate exhibition of industrial transports under the auspices of the Automobile Club of Maryland, Feb. 26-28, in which more than 70 models were displayed by 22 agencies.

The Fifth Regiment Armory was beautifully decorated for the pleasure car show, which immediately preceded this event. In addition to the vehicles on display within the hall, most of the dealers had demonstrators outside, and full opportunity was afforded for complete investigation of the problem of mechanical haulage. The exhibits may be described briefly as follows:

Atterbury Motor Car Company of Maryland, three and five-ton Atterbury; Callahan Bros. Company, Morgan, two-ton delivery, five-ton truck and three-ton chassis; Chase Motor Truck Company, one Chase truck; Consolidated Gas Electric Light & Power Company, two and three-ton vehicles of company's own make; Enterprise Fuel Company, three two-ton Gramm trucks and three-ton Gramm coal dumper; Everitt Auto Company, one and three-ton trucks on Everitt chassis; Ford Auto Company, Ford delivery wagon; Foss-Hughes Company, five-ton Pierce-Arrow truck and stripped chassis showing worm drive; International Harvester Company, three 1000-pound International delivery wagons; International Motor Company, 4.5-ton Saurer, one and two-ton Mack trucks, three-ton Mack brewery truck, four-ton Mack hose wagon, and five-ton Mack self-dumper; Kelly Motor Truck Company, one and three-ton Kelly; Lozier Sales Company, five-ton stripped Lozier chassis; Mar-Del Mobile Company, two-ton Packard stake wagon and three-ton chassis; Mount Vernon Motor Company, 1.5-ton Autocar and stripped chassis; Neely & Ensor, four Alco trucks ranging from two to five tons, and two Lippard-Stewart vehicles; Norwood Bros., Inc., three-ton Seitz stake truck, one-ton Seitz chassis, and 1000-pound Lincoln wagon; Oakland Motor Company, three 1.5-ton Federal trucks; George R. Snodeal, 6.5-ton imported Commer chassis; Standard Motor Car Company, 1000-pound Cadillac chassis; Stoddard-Dayton Auto Company of Baltimore, three-ton Sampson chassis and 1000-pound delivery wagon of same make; White Automobile Company, 1500-pound wagon, three and five-ton trucks and three-ton chassis, all of White make; Zell Motorcar Company, five-ton Peerless chassis and 1500-pound Chalmers delivery wagon.

CINCINNATI'S COMMERCIAL CAR SHOW.

For the second time in the history of the Cincinnati Automobile Dealers' Association a special motor truck display was held in Music Hall, Cincinnati, O., during the week of Feb. 26-March 2. The event followed the pleasure car show of the previous week, and the same decorations were maintained for both exhibitions. The attendance was even larger than last year, and it is understood that much business was transacted.

Among those who made display were the following: Leyman-Buick Company, Mack, Saurer; Citizens Motor Car Company, Packard; R. C. Crowthers, Alco, Veerac; U. S. Motor Truck Company, United States; Hanauer Automobile Company, Pierce-Arrow; Psthelhoff & Braukmann, Hatfield; Dr. H. C. Wendel, Dorris; Haberer & Co., Cino; Cincinnati Automobile Company, Peerless, Pope-Hartford; International Harvester Company of America, International; Schacht Motor Car Company, Schacht; Chicago Pneumatic Tool Company, Little Giant; Fischer Auto & Service Company, Speedwell; Herold Motor Company, Reo; Miller, DuBrel & Peters, Avery, Ideal; Otto Armleder Company, Armleder; Cincinnati Motor Truck Company, Federal; Glow Electric Company, Glowicke; Wilberding & Brandewedie, Modern; F. B. Williams Company, Sandusky.

MORELAND TRUCK FROM CALIFORNIA.

Claiming to be the third city in the country, with reference to number of commercial cars in active use, and realizing that California business men are alive to the possibilities of increasing the scope of their business by a really effective delivery system, Los Angeles, Cal., is taking active interest in an effort to become a large automobile manufacturing centre. Among the recent announcements is that of a new truck concern, the Moreland Motor Truck Company of that city.

Walter L. Moreland, manager of the company which bears his name, is a pioneer in the California automobile industry, having been connected with the first concern to manufacture pleasure cars in that commonwealth. The Moreland company will build trucks exclusively, the models ranging from 1.5 to 10 tons capacity. Several already have been constructed and have given good service in the hands of their owners. Continental motors and Timken axles are utilized, but all other parts are manufactured in the factory of the company at Wilhart and North Main streets.

PRODUCING GASOLINE RAILROAD CARS.

The Marion Motor Section Car Company, Marion, Ind., has been incorporated with capital of $300,000, for the production of a gasoline railroad inspection car, invented by W. O. and J. D. Worth of Chicago. The Worth brothers have been making this vehicle in small quantities for some time, but it became evident recently that additional capital would be necessary in order to keep abreast of the orders. Stockholders in the Indiana Auto Parts Company of Marion became interested in the proposition and the organization of the new concern resulted.

The car is equipped with a 20 horsepower gasoline engine, and has capacity for carrying 16 persons and hauling three trailers, making a total weight of not less than 50,000 pounds, at the rate of 25 miles an hour. It is claimed to have all the speed and ability of a steam locomotive, either forward or backward, up to 40 miles an hour, and without the use of a gear in its construction. The weight is light, and nickel and other special steels are used throughout.

The factory will be located in Marion. The work of drawing plans and specifications has been going on for some time, and the company is ready to produce from 12 to 15 cars daily. It is understood that railroad companies are anxious to take all that can be manufactured.

MARYLAND FIRM ENTERS TRUCK FIELD.

Believing there is a decided market for a light delivery wagon of the proper construction, the Kuhner Engineering Company, Oxford, Md., has turned its attention to the production of trucks of this character. The concern has been producing automobile motors for some time past, and will utilize this product in the new undertaking. The factory has a tidewater frontage, and is 50 by 160 feet. The officers of the company are: President, H. E. Kuhner; vice president, Alexis G. Pascault; secretary, George M. Wingard; treasurer, William B. Shannahan.

THE A B C OF MOTOR TRUCK OPERATION.

A Simple Exposition of the Principles Underlying Operation, Maintenance and Repair of All Motor Driven Commercial Cars, Describing Details of Components. Part XVI—Outlining Principles of Selective Type Transmission.

By C. P. Shattuck.

REFERENCE has been made to the planetary form of transmission which has many advantages, inasmuch as it is a device especially adapted to being handled by the most inexperienced without liability of damage. It possesses a feature also shared by the sliding gear system, that of furnishing a direct drive on the high speed, this being brought about by locking the high speed clutch disc and by the transmission revolving as a unit as previously explained. Its greatest drawback lies in the production of but two forward speeds and a reverse. Although providing a quiet and efficient means of transmitting energy to the traction wheels when the high speed is utilized, there is more or less noise attendant upon the use of the other gears after a time. It is very compact, occupies but little room, and when the gears are enclosed in oil tight casings, and these packed with suitable lubricant, both wear and noise are eliminated to a large extent.

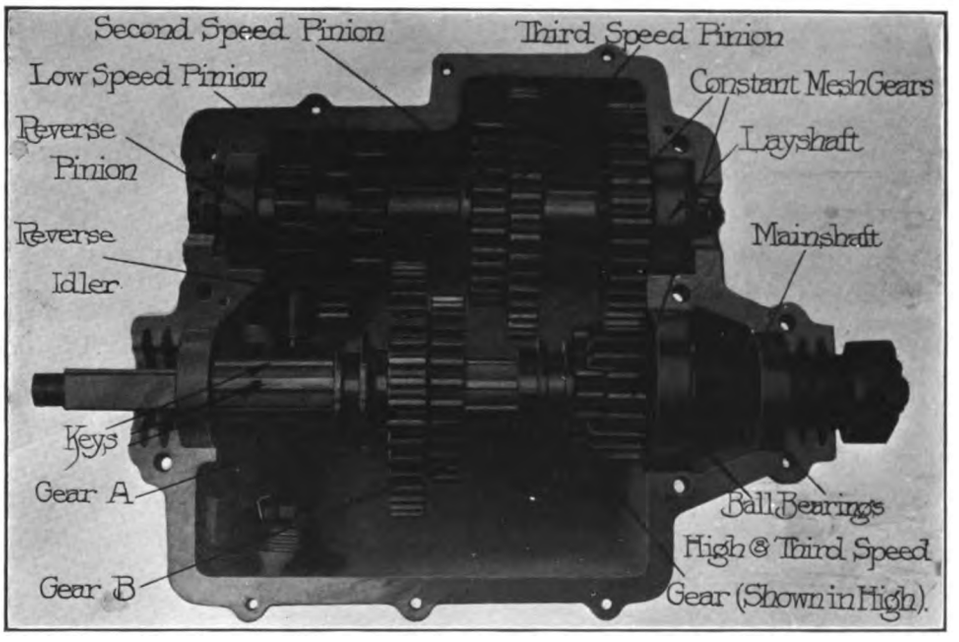

Fig. 65—Depicting the Components of a Four-Speed Gearbox of the Selective Form—The Third or Direct Drive Member Is Shown in Engagement.

At Fig. 68 is depicted a conventional form of planetary transmission utilized on mechanical transports with part of the casings removed to show the gears and the arrangement and location of the brake drum. These drum members revolve and stopping the motion of one by means of a suitable brake band will give a slow speed forward, while clutching the other drum will bring about a reverse movement. As the gears are continually in mesh the speed changes may be made easily and all danger of stripping the gears is eliminated. Owing to the utilization of brake bands, the low and reverse ratios are obtained in a gradual manner even if they be operated by an inexperienced driver.

To obtain the high or direct drive the high speed clutch disc is forced against the drum casings by small fingers or bell cranks, being expanded by a cone member. When the cone is in place, the pressure between the fingers and the clutch disc locks the gear drum to the shaft and causes the whole to revolve as a unit.

The high speed may consist of a cone, or a number of discs faced with fibre, or asbestos and wire cloth as friction facing, and provision is made for adjustment by screwing the spider carrying the bell cranks so that they will be brought closer to the disc or cone. The braking bands are lined with various materials and to derive efficiency these members must be so adjusted as to grip firmly when in service, but not bind when the high speed is employed and the transmission revolving as a unit. Should undue friction be set up it will act as a brake when the vehicle is being operated on the direct drive.

The planetary transmission is made in several forms but the basic principles upon which it operates are similar. Control of the three speeds may be by pedal or lever. For example, the low speed and the reverse clutching members may be actuated by a separate pedal and a hand lever be utilized to operate the high. Some forms may provide for operation by pedals alone. It is obvious that this type of transmission has its advantages, among which may be mentioned that the reverse may be employed as a brake in the event of the usual members failing to operate. A four-speed planetary transmission would be complicated, difficult to construct as well as apply, and to provide for more than two forward speeds the sliding gear is employed. This permits of three or four forward speeds and a reverse, according to the design, thereby giving a wider range of speed gears, and permitting the operator, no matter what road conditions he may encounter, to secure from the motor a very economical expenditure of power.

Sliding gear arrangements may be divided into two classes; namely, progressive and selective. The selective type differs from the non-selective inasmuch as it permits the choice and use of any set of speed gears instantly, without passing through intermediate gears. In the use of the non-selective type, should the car be running on the third or direct speed, and the operator desires to change to the first, he is compelled to disengage the third speed, and to engage and disengage the second before the desired low may be reached. This is overcome in the selective type, where the operator merely disengages the speed gears in use and engages the gears desired without being required to consider intermediate members.

The components of a sliding gear are outlined at Fig. 65, which depicts a conventional type of selective transmis-

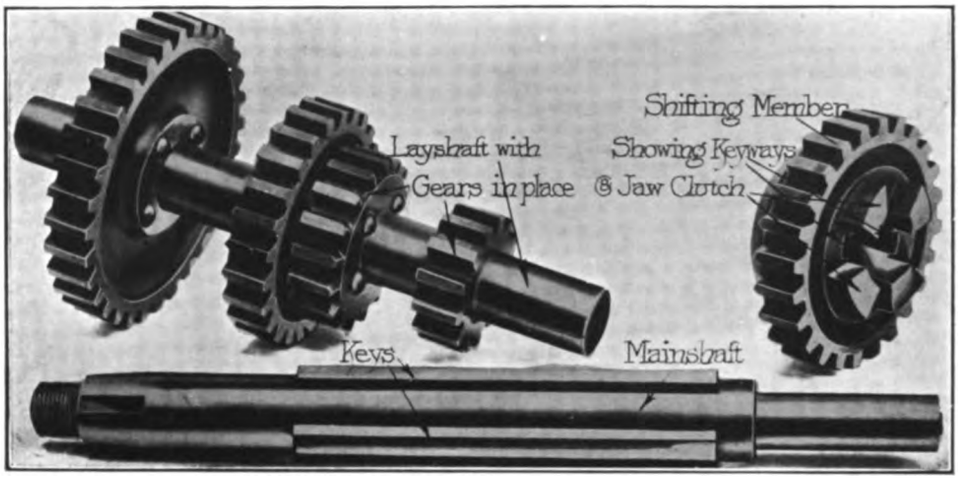

Fig. 66—Showing Layshaft of Sliding Gear Transmission, Shifting Member and Jaw Clutch, Which Is Fitted with Keyways to Slide on Mainshaft.

sion having four speeds forward and reverse. The engine and clutch have been previously described and their method of operation made clear. Upon the mainshaft of the gearbox, which really is a continuation or extension of the engine shaft, are carried a number of gears, these corresponding to similar members mounted upon another shaft parallel to the main member and in proximity to it. The second is termed the layshaft and it will be noted that it is fitted with a gear which is in constant mesh with another and smaller gear fixed to the main shaft. Upon the latter, which is round, although it may be of square design, are located movable gears, this action being secured by providing four milled keys which fit into four slots cut through the centre of each gear. This arrangement may be considered as solid on the shaft, inasmuch as the keys and shaft are one piece.

By reason of the keys on the shaft and the corresponding slots in the gears, the sliding gear is one that may move longitudinally on the shaft, and at the same time be so held by the keys that it must revolve uniformly and constantly with the shaft. At Fig. 66 is depicted the main shaft with keys, also a jaw clutch or shifting member with keyways outlined, and it is obvious that when this is fitted to the shaft it practically forms a solid, although slideable member. In other words, it has a free movement along the shaft when moved by means of a collar and yoke, but is no more independent of the shaft in the matter of revolution, than if the shaft and gear were one piece.

The gears upon the layshaft are fixed, as will be noted in the illustration, and these members are revolved by means of a gear in mesh with another on the main shaft and these are termed the constant mesh gears. Furthermore the gears on the lay and main shafts are so spaced that but one pair may be in mesh at a time; that is, care is taken in spacing the different members so that there will be no interference or striking between gears which do not form pairs and are not intended to mesh.

The number of gears fitted depends upon the speed employed and when four forward are utilized as in the gearbox at Fig. 65, the main shaft is equipped with three shifting members which gives the reverse, lowest and intermediate speeds. The other shifting member shown in the direct drive position, which is the third forward ratio, also serves for the fourth speed, which is higher than the direct drive. The constant mesh gear driven by the engine drives the constant mesh gear on the layshaft and the former causes the latter to revolve. When the shifting member is moved from the direct drive position so that it meshes with the largest layshaft gear, the main shaft rotates at a higher speed than the constant mesh gear driven by the motor which drives the layshaft.

If the operator desire to change from the direct to the second or intermediate speed, the clutch is disengaged and by means of a shifting collar which is actuated by the gear shifting lever, the shifting member fitted with the jaw clutch is moved out of engagement and another movement of the lever moves the gear B into engagement with the second speed pinion on the layshaft. If the low be desired the gear A is moved backward into mesh with the low speed pinion. As previously explained, with the selective type of transmission a direct change may be made from one speed to another at the will of the operator.

Assume that the driver desires to move the vehicle backward, an operation involving the use of the reverse mechanism. This is operated by the same lever that actuates all forward speeds, the only difference being that the gear on the layshaft does not mesh directly with the shifting member on the rear part of the main shaft, but instead these two gears engage an intermediate member, known as the reverse idler.

To explain best the operation of this member it must be understood that when the drive is transferred from the forward

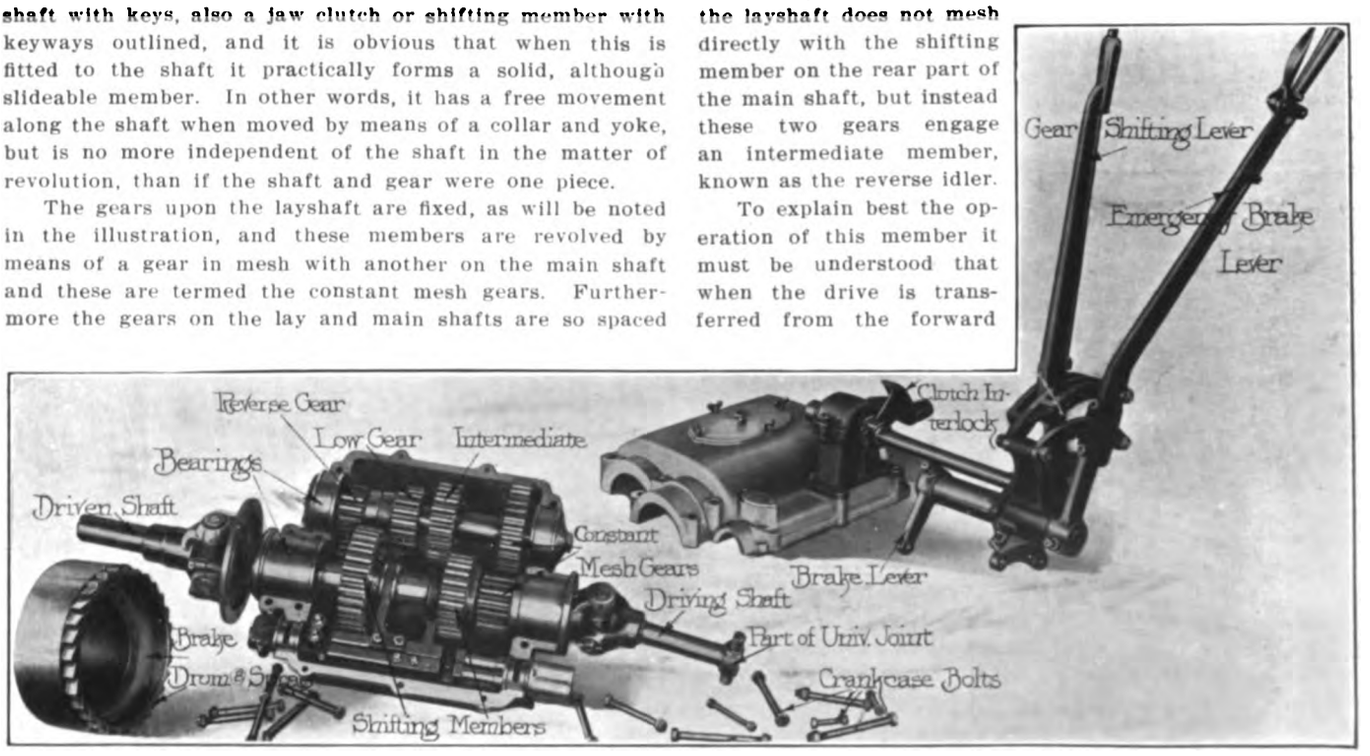

Fig. 67—Gearbox of Three-Speed Selective Type, Depicting the Gear Shifting Mechanism, Operated by Hand Lever, Attached to Upper Half of Transmission Case.

Digitized by Google

part of the main shaft to the layshaft, the latter revolves in an opposite direction. When this motion is transmitted from the layshaft back to the rear part of the main shaft, the direction of rotation is again reversed, so that the rear part of the main shaft revolves in the same direction as does the forward section. If, between the gear on the layshaft and main shaft, an intermediate pinion be interposed, the latter will revolve in exactly the same direction as does the forward end of the main shaft, and if the intermediate pinion be meshed with another on the rear part of the main shaft, the motion of the latter will be similar to that of the layshaft, and directly opposite to the direction of the forward part of the main shaft. Thus, by the intervention of a reverse idler, a backward movement of the vehicle is obtainable.

Regarding the ratios or different speeds brought about by the use of the pinions: Assume that the gear A is moved into engagement with the low speed pinion. The latter will impart motion to the movable gear and as the latter is larger, the low speed pinion must make a certain proportionate number of revolutions to rotate the main shaft pinion. With the second speed pinion in mesh it is obvious that the speed of the main shaft is accelerated, and so on up to the direct drive.

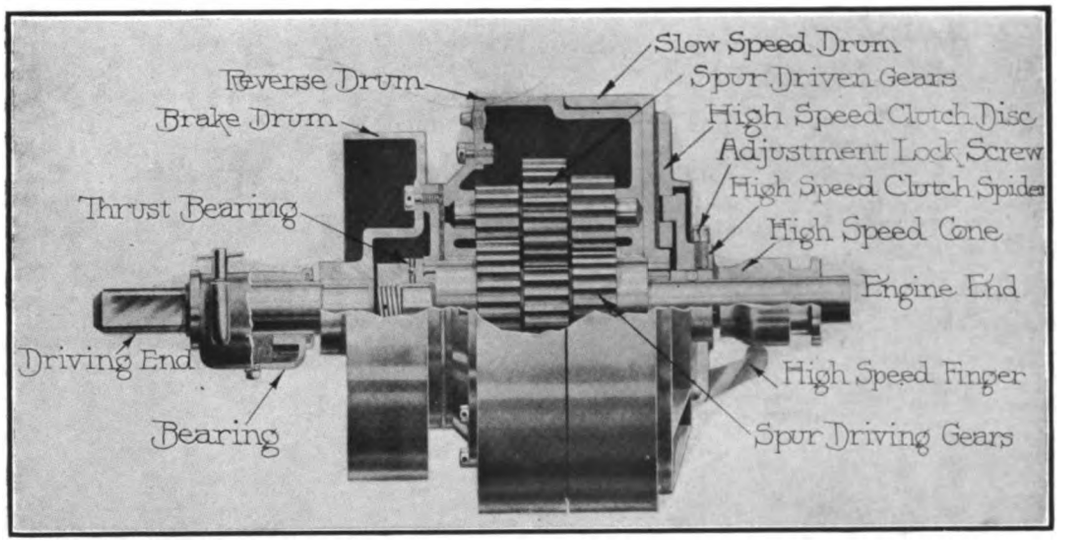

Fig. 68—Outlining Conventional Type of Planetary Transmission Affording Two Speeds Forward and Reverse.

The neutral effect is brought about when none of the speed pinions is in engagement with the shifting gear members. Under these conditions the clutch may be in and the layshaft will be revolving because of the motion imparted by the constant mesh gear.

Changes of speed are secured through the means of a lever, this being depicted at Fig. 67. The member in this instance is at the right of the operator although its location may be at the centre or left, depending upon the design of the car. The gear shifting lever has its movement restricted by what is known as a selective quadrant; that is, a metal frame so slotted that the lever may be pushed forward or backward in either of the two parallel channels. If the lever be moved forward in one of the channels, it brings one set of gears into mesh. If operated in the opposite direction in the same channel, it releases those gears already in mesh and slides a different set into engagement. In like manner all the various combinations are secured.

The mechanism controlling the changing or shifting of the gears, is by two rods parallel with the gearshaft, each of these having a shifting yoke attached thereto engaging in a groove on the shifting member hub. Each rod is equipped with a U shaped member in which a lever operates, these being actuated by the forks on either side of the inside segment member. The gear shifting lever is hinged at the bottom so that it may be oscillated from side to side, first engaging the inside fork, which has two positions, then being shifted through a slot and engaging the outside forked member. The inside fork operates the reverse and low speed, the outside the intermediate and high. The shaft which operates the high and intermediate members telescopes in the hollow shaft to which the low and reverse operating finger is attached. The forked member engaging the side of the control member nearer the operator is attached to the hollow controlling shaft.

An interlocking mechanism, the function of which is to prevent throwing into engagement two different combinations at the same time, is depicted at Fig. 67. The device also holds disengaged gears in such a position that they cannot be shaken into engagement and prevents the meshing of gears when the clutch is engaged. In other words, the interlocking device requires that the energy of the motor be interrupted by means of the clutch before it is possible to bring gear teeth into mesh.

Referring again to Fig. 67, it will be noted that the brake drum is equipped with a ratchet and pawl arrangement. This is located just back of the transmission case and is utilized when the vehicle is stopped on an upgrade. This service brake drum rotates at propeller shaft speed, or about eight times that of the rear wheels. The device is fitted with a positive interlocking mechanism which prevents the pawl from being thrown into engagement with the ratchet when the reverse gear is in mesh, or the use of the reverse member when the pawl is thrown into contact with the ratchet. By the use of the device it is claimed that a loaded vehicle may be held on any grade without the application of brakes, and that the machine may be restarted without the simultaneous releasing of the brakes and letting in of the clutch.

(To Be Continued.)

Ed. Note—The next installment will consider the progressive type of transmission and other forms, including those in which the gears are in constant mesh.

DEMAGNETIZATION OF MAGNETS.

The demagnetization of the magnets of a magneto is not generally understood. Although this seldom occurs the members may become demagnetized and when such is the case it usually is due to improper wiring. It is caused by passing the current of a battery through the magneto windings. Some makers of magnetos utilize the colored wire cable scheme to facilitate the installation of the wiring and to prevent mistakes, it being only necessary to connect each colored wire to a terminal of corresponding color. This plan is adopted by the Remy Electric Company, Anderson, Ind.

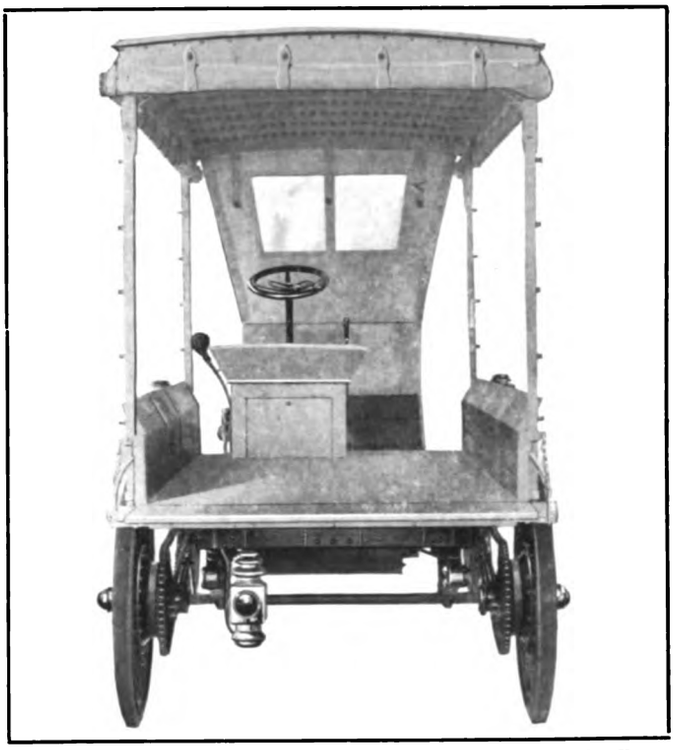
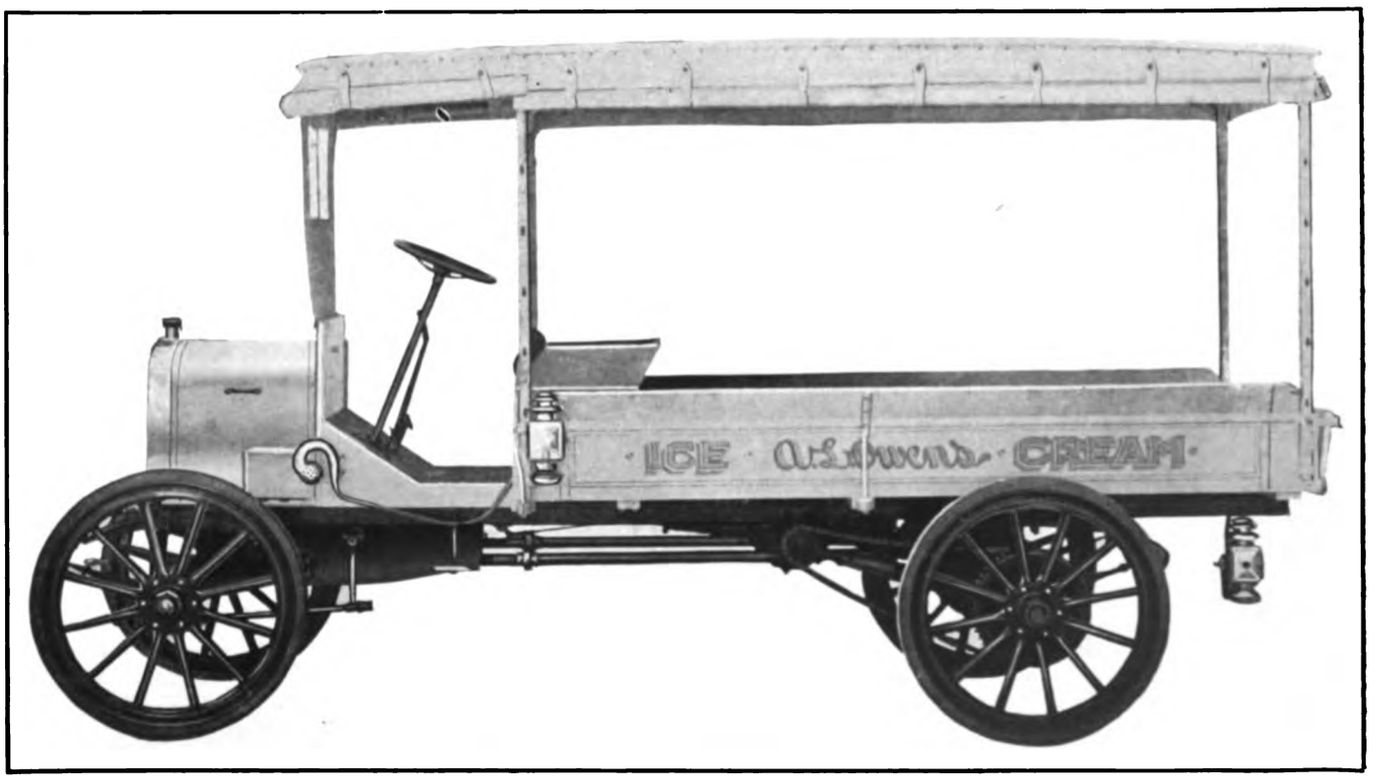
SPECIAL BODY FOR ICE CREAM DELIVERY.



BECAUSE of the perishable nature of the product, the motor truck makes a particular appeal to those engaged in the delivery of ice cream. The possibilities for increased speed are such that the packages may be delivered with much less danger of loss, effecting an economy in addition to the ability to carry larger loads and make a greater number of trips in a given time than with horse drawn equipment. However, as with many other lines of business, it is desirable to consider the body problem with special reference to the work the vehicle will be called upon to do.

It is obvious that if one of the elements of economy in this utilization of the mechanical transport is its ability to carry a larger load, some provision must be made for securing the most advantageous use of the space available. As is well known, ice cream is packed for shipment in tubs and pails and it is somewhat impossible for these to be carried on top of each other. It follows that the floor of the truck must be utilized to its fullest extent, if the maximum carrying ability of the vehicle is to be realized.



Accompanying illustrations present the solution offered by the Sullivan Motor Car Company, Rochester, N. Y., maker of Sullivan trucks. This machine was constructed for a Rochester ice cream dealer and was displayed during the recent automobile show in that city. The body was finished in white, lettered and striped in gold, and the running gear was red. Its attractive appearance was a matter of much comment during the exhibition, and a number of orders for duplicates of the construction were secured.

The smaller view gives a splendid idea of the interior as seen from the rear. This indicates particularly the method of providing for the utmost practical use of the floor space. It will be noted that the driver's seat is designed to occupy but half of the space in the front of the vehicle, and the openings on either side are available for storing packages of varying size.

This body has a width of 46 inches, inside, and that portion back of the seat is seven feet six inches in length. One-half of the body has a carrying space of nine feet nine inches, and this additional two feet and three inches is of decided value in the ice cream business. It may be added that the top is supplied with hinges so that it may be entirely removed, the stakes being designed to fold up with the top. While constructed specially for the ice cream dealer mentioned, among the orders taken at the show three were for plumbers and another for a rug and carpet concern.

Interior of Sullivan Ice Cream Wagon as Viewed from the Rear.

Special Body Design for Ice Cream Delivery Constructed by Sullivan Motor Car Company, Rochester, N. Y., Mounted on Regular Sullivan Truck Chassis.

SOLVING THE PROBLEM OF THE GAS TURBINE.

What Is Expected of the New Internal Combustion Engine—Some of the Difficulties Which Must Be Overcome—Progress Made and Suggestions as to the Possibilities.

MORE power, less weight, elimination of noise and reduction in complications are among the objects sought in the development of gasoline engines for the propulsion of automobiles and aerial craft. With some engineers there is the suggestion that the present types in service have reached the limits of their possibilities in these respects. Leaving aside the merits of that position, it will prove of interest to consider some of the methods advanced for the solution of the problem in another manner.

For many years the gas turbine has presented a fascinating study in this connection, and while the progress has been rather less noticeable in America than abroad, it is worthy of mention that some degree of success has been attained. And it is especially in the features above enumerated in which the inventors expect superiority from the gas turbine. The difficulties to be overcome do not appear to be insurmountable; in fact, there already are constructors who claim to have solved the problem.

Principles of Construction.

In order to appreciate the progress in the development of the gas turbine, it is necessary to understand at least in a general way, the principles underlying its construction and operation, as well as some of the difficulties confronting the engineers now engaged in working out the proposition. The chief distinction between the gas and steam turbine lies in the fact that the first generates its own power within itself, while the latter is dependent upon a steam boiler for the power which it uses. For this reason, the gas turbine sometimes is termed a power generator.

The experiments made thus far may generally be classed under two somewhat distinct branches of design. One of these types represents the principle of a continuous burning of the gas and air mixture within a closed chamber, by means of which the gases are expanded and forced to and through the turbine wheel. This mixture is introduced to the chamber by means of a pump driven by the shaft of the turbine wheel.

Simplest Form of Gas Turbine.

A theoretical illustration of this type is shown in Fig. 1 A. In this, the chamber a, in which the mixture is burned by means of a continuous series of electric sparks, is protected from heat losses by a heavy asbestos covering. The fuel is pumped into this chamber through conduits b and c by means of a pump d, which is driven by the shaft of the turbine wheel e.

This is the simplest form of gas turbine, and the principles described have been the subject of much experimentation. However, it is considered improbable that success will be achieved along these lines. In the first place, it will be found difficult, if not impossible, to construct a pumping system qualified to act against such pressure and heat. In addition the mixture of partly burned and fresh gasoline and air hardly will be expected to burn properly. Then again, there is an ever increasing heat, which by continued use will result in spreading or warping surfaces which must be kept smooth and tight.

A More Successful Type.

The second principle is illustrated theoretically at Fig. 1 B, and this appears to offer better possibilities of success. In this, f represents the turbine wheel, which is connected with a rotary pump g. The explosion chamber is outlined at h, and this is designed to explode the mixture at rapid intervals. The position of the valves, through which the burning gases pass to the turbine wheel, is shown at i, and k is the spark plug by means of which the charge is exploded. The double valve at l regulates the admission of fuel and air the gas conduit m fitting into that of the air n.

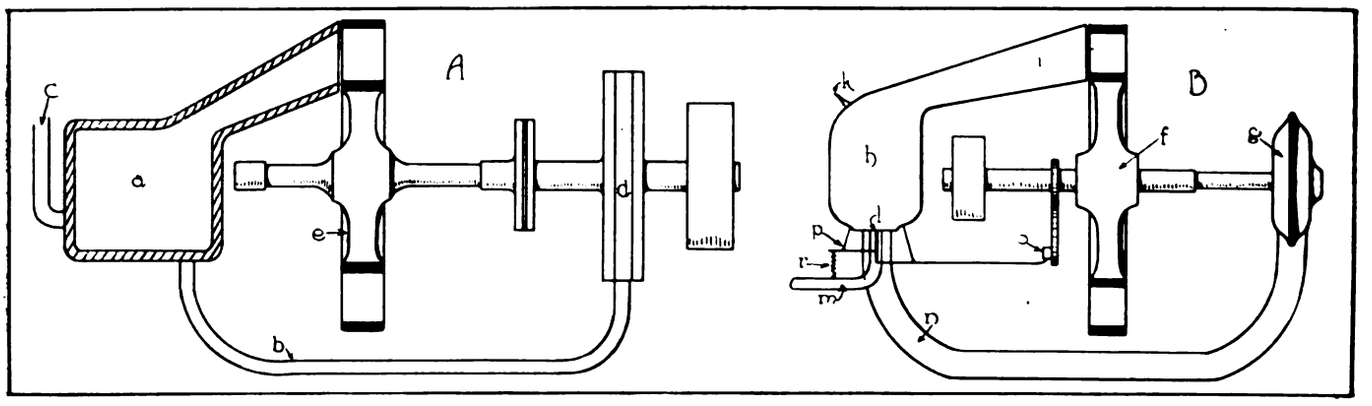

Fig. 1—Theoretical Sketch, Showing Principles of Gas Turbines: A, Simplest Form, or Continuous Burning Type; B, Consecutive Explosion Design.

The construction of this double valve is such that the gas member is situated within the air member. The former is operated by a connection with a cam o, driven by the turbine, while the air valve is worked automatically by the pressure of the exploded mixture, and by means of the lever p and the spring r, which act to hold it open.

The operation of this type of gas turbine is as follows: By turning the turbine wheel by hand a number of times, air is forced through the explosion chamber, valves and flanges of the turbine wheel. After a sufficient number of turns, the gas valve will be opened and gasoline will be drawn into the chamber h, forming the explosive mixture. Immediately after the gas valve is closed, the spark plug ignites this mixture, which expands and closes the air valve. The exploded gas then passes to and through the turbine wheel, causing it to rotate. The air valve remains closed until the pressure of the expanded gas has left the cylinder, at which time it opens again and a new charge of fresh air and gasoline is taken in. This new charge not only has the advantage of driving the rest of the old one into the wheel, but it also has the effect of cooling the chamber and valves, which otherwise would become too hot for continued service.

Multiple Explosion Chambers.

An engine of this type can be operated when the power of the explosions gives a greater turning pressure to the axle of the turbine than is taken up by friction, pump re-

Digitized by Google

sistance, etc. In order, however, to obtain a working power surplus it becomes necessary to operate the engine at a much greater speed than is possible with only one explosion chamber. Therefore, a number of chambers is used, sometimes as high as 10. The more chambers employed, the greater surplus of power and the steadier will be this power. It may be pointed out that perhaps the most important feature of any turbine is that the source of power shall be as constant as possible.

There is one difficulty which presents itself with the use of many explosion chambers, and that is with reference to the intense heat engendered, especially when these chambers are within the wheel. It is possible to overcome this by using a water circulation cooling system, in which event the turbine flanged wheel has water chambers. By this plan, much of the water is soon turned to steam, and though the steam is sufficient to cool the surfaces of the flanges, the heat is so great that it is found necessary to employ a large cooler, capable of condensing the steam generated. For this reason, the water circulating plan generally is not satisfactory.

Valve Difficulties.

There also are other difficulties which confront the constructors of this type of gas turbine. Because of the rapid valve action necessary immediately after the explosion, it has been found that only the automatic inlet valve can be used, and even this is difficult to construct in such manner as to yield satisfactory results. The conditions of the automatic inlet valve are much different here than in the gasoline motor of the piston reciprocating type, since in that case it is closed by the compression stroke of the piston. In the turbine this compression does not exist, and the valve must be closed entirely by the pressure of the explosion, and it has been found that they generally are too heavy and complicated in design to be able to close with a speed equal to that of the exploded gas. The result is that the exploded gas passes back through the valve, either igniting the incoming charge or destroying its firing qualities by mixing with it. The difficulty of firing the charge after the valves have closed, and in using a mechanically operated valve, lies in that as the firing mixture has practically a continuous flow, only halted by the explosions, the closing of the valve would allow the gas time to escape into the wheel before the explosion could burn it.

Regulation of Charge.

Another problem is the proper regulation of the gas and air mixture with reference to the different speeds of the engine. Some success has been noted in the use of regulators which control the intake gas valve to the extent of causing it to open wider as the speed of the turbine increases. A device of this nature, which has been used by Friedrich Hansen, Hamburg, Germany, is shown herewith by theoretical drawing at Fig. 2 A.

This device is operated in the following manner: Between the valve spindle s and the cam n is assembled a sliding member e with a cam shaped lower surface. This sliding member is operated as shown in the drawing, by the regulator r, which is in turn driven by the turbine shaft. The backward and forward movement of the member e regulates the size of opening for the valve f, as can be seen in the drawing.

The proportions of the cam surface on the member e represent the different openings of the valve. That portion of this cam to come between the spindle s and the cam n at the highest speed of the motor, and therefore at the greatest opening of the valve, is represented by the dotted line a-b. From b to c represents a movement of the member e when the speed of the turbine has exceeded the normal, in which case the valve opening would be reduced or entirely closed. The curve from b to d represents the different valve openings for empty running and for normal revolutions.

Hansen's Gas Turbine.

A further interesting experiment of Engineer Hansen is illustrated by the drawings at Fig. 2B and C, showing a single drum form of explosion chamber within the turbine wheel. As can be seen at C, the air inlet valve x and the gas inlet y are located within the turbine axle centre. The gasoline is reduced to a spray by being pumped through small openings into the explosion chamber w. The charge is regulated by means of a cam driven by the shaft of the turbine. After a number of trials, the automatic air valve was selected in preference to the mechanically driven member. The exploded gas passes out through eight conduits, designated by z in B and C.

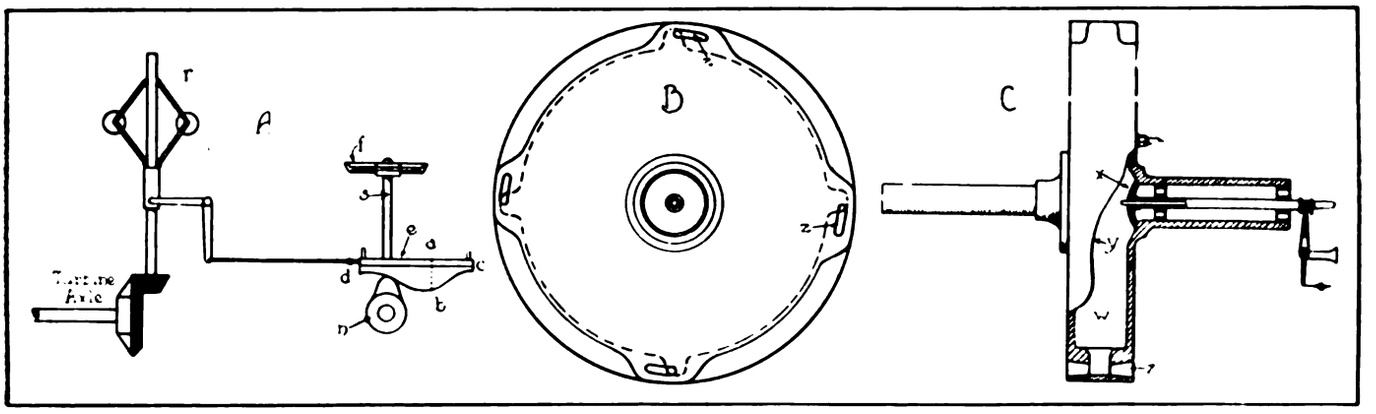

Fig. 2—Theoretical Drawing of Gas Turbine Components: A, Regulator for Controlling Gas Charge; B, End View of Revolving Explosion Chamber; C, Section Through Same.

Under test this turbine is said to have reached a speed of approximately 2500 revolutions a minute with 30 explosions a second. It is stated, however, that the successive rapidity of the explosions appeared to be of a somewhat similar nature to that of a constant burning of the charge. When the turbine had been in operation 30 minutes the ports were red hot, and after an hour's continuous running this heat color had spread on the outside of the casing to a circle near the axle. The heat at this point seemed to have reached its maximum and the color spread no further.

The weight of the turbine wheel was 45 kilograms (about 99 pounds), and it turned on ball bearings of the normal type. The fuel used is said to have been 2780 grams (about a gallon) of kerosene and gasoline an hour. Kerosene could not be used at first, but only after the engine had been running a sufficient length of time to generate the heat necessary to vaporize it.

Pounds Pressure Obtained.

A plotted curve of the pounds pressure obtained by the exploded gas at the different speeds of the successive explosions a second showed between 70 and 80 at one explosion and about 10 for 24. This rapid reduction in the pressure

Digitized by Google

of the exploded gas by the increasing number of explosions a second is held to be due to the fact that the speed had the effect of reducing the richness of the charge correspondingly. With a later model of somewhat similar design, Mr. Hansen reports better results. In this instance the power pressure developed was about 70 at six explosions a second and approximately 55 at 18.

Based on the experience obtained by the trials with these models, Mr. Hansen has constructed a new motor, that shown at Fig. 3, with which it is claimed that such practical results have been obtained the inventor feels justified in saying that he will soon be able to offer to the industry a tested, practical gas turbine for automobile and aviation use, well qualified to do the work and to enter the field of competition with present gasoline engines.

This turbine is made up of three cylinders, assembled in such manner, however, that they constitute one revolving explosion chamber. The air intake is arranged for in a similar manner to that described in the previous figure; that is, through the axle of the turbine wheel. The gasoline or kerosene enters through the centre of the air valve, and is forced into the explosion chamber through a spray valve by the pump a at Fig. 3 A.

The explosion operates in reaction valve reversing chambers, passing through the flanged wheel to the open air through the exhaust tube e, seen at the bottom of the casing in B. The spark plug f is used for firing any gas which may escape in the casing of the flanged wheel when the turbine is being started. Spark plug g constitutes the point of friction contact which conveys the firing current to the friction points of the spark plugs, fixed to the explosion chambers, as they revolve with these chambers past the plug g.

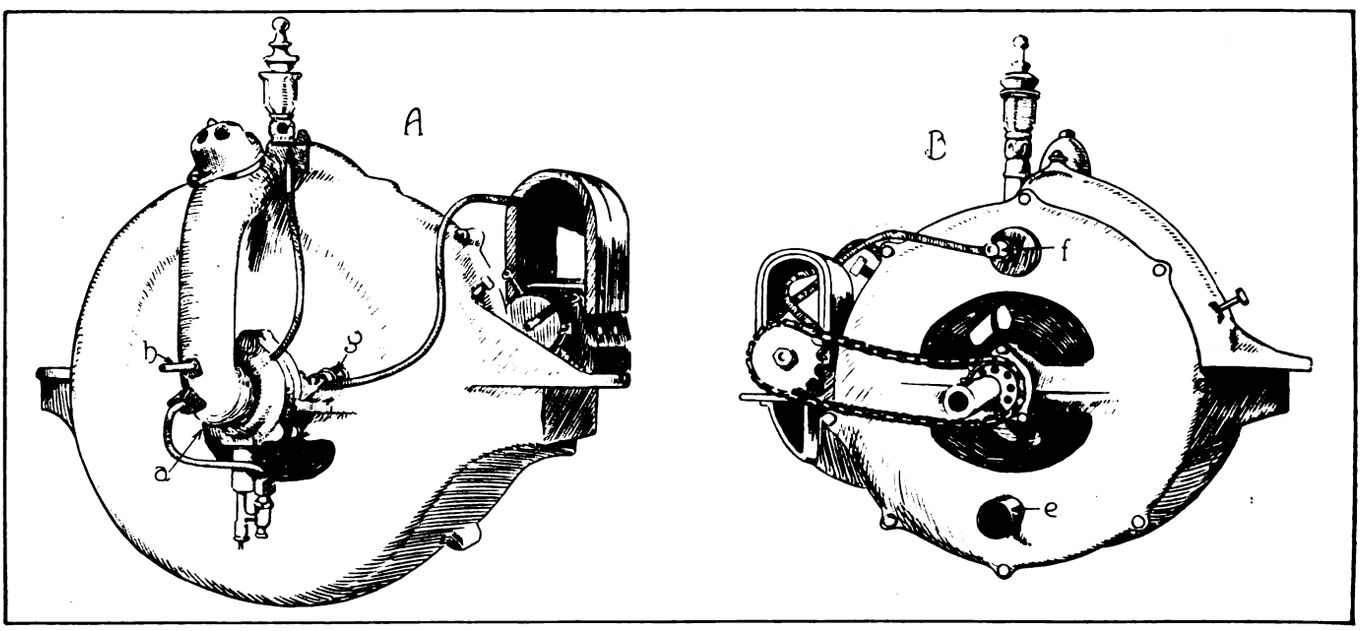

Fig. 3—Inlet and Exhaust Sides of Gas Turbine Constructed by Friedrich Hansen of Hamburg, Germany, and Given Practical Tests.

Method of Cooling.

The rapid revolutions of the chambers, assisted by the ventilator, which also revolves with the main axle, generate a forceful air current which has proved sufficient to keep the power plant cool and in good working condition. The cooling air, which has a pressure of a 24-mm (.94-inch) water column at a turbine speed of 1200 revolutions a minute, is exhausted from the tube h. For the purpose of allowing this cooling air to circulate through the parts, the axle is hollow and connected with the explosion chambers at three points only.

At first, the air which was heated by its circulation through the turbine, was used for the fuel mixture as well, but it was found that cold air must be employed for this purpose, owing to the fact that the hotter was the air the lighter was the fuel mixture. The much greater expansion of the cold air on entering the chambers added materially to the power of the engine, and it was only after making use of this that practical results were attained.

Thus it will be seen that the industry apparently soon will have the opportunity of testing the practical gas turbine, and it may be added that it is to be hoped the results will justify the expectations of many who believe that in this type of motor the ideal power plant is to be realized. Of course it will depend upon how far it is possible to overcome present difficulties of construction in the engine itself, and when these are overcome the question of efficiency with regard to the consumption of fuel will be another important point for consideration.

Considering Power Transmission.

It also may be pointed out that a matter of some importance will be the problem of transmitting the energy, inasmuch as the possibility of constructing a gas turbine of light weight and high power undoubtedly will depend largely upon its high speed ability. It hardly would be practical to employ any of the present types of gear transmission with a very high speed engine in automobile work.

It has been suggested that perhaps this difficulty could be overcome by utilizing electric or oil hydraulics. Electricity would appear to have particular qualifications, as the high speed of the turbine would make it possible to do the work with a comparatively small dynamo of light weight, which in automobiles might be attached directly to the turbine under the hood. This with the storage batteries for reserve, light and heat, and two electric driving motors in the wheels would comprise the entire power plant and transmission mechanism. Or, one electric motor located just behind the dynamo under the front platform extension and connected with the present design of live axle and differential might be used instead of two motors without the differential.

For heavy trucks a combination of a practical gas turbine with the oil hydraulic transmission would appear to offer special advantages. With this system, as with the electric transmission of power, the speed of the car does not depend upon that of the engine. In other words, the speed of the power generator may be kept constant, while an even regular graduation of the increase or decrease in speed of the vehicle is possible.

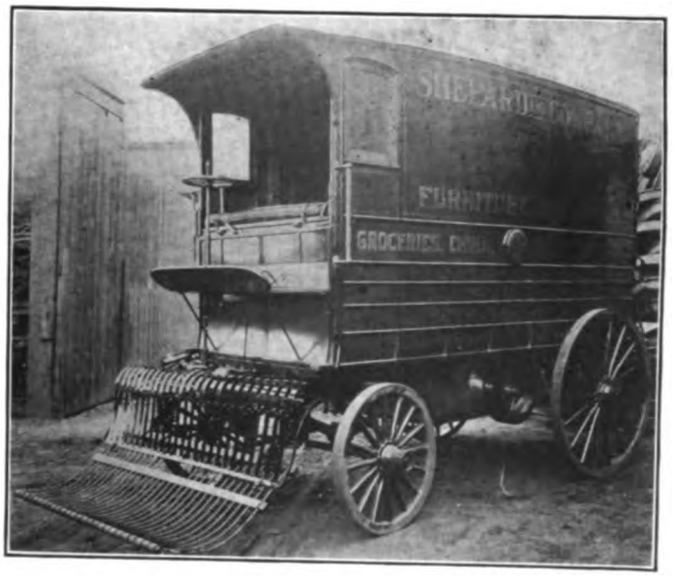
AMERICA'S FIRST INDUSTRIAL POWER WAGON.

Novel Power Plant Designed by L. F. N. Baldwin to Drive Furniture Van for Department Store at Order of John Shepard, Jr., of Providence.

WHAT is believed to be the first industrial power wagon constructed in America was built to order for John Shepard, Jr., executive of the Shepard Company, which conducts a department store at Providence, R. I., by the Cruickshank Engine Company of that city, in 1896-7, to designs by L. F. N. Baldwin, the noted racing driver. This vehicle was delivered to the Shepard Company in the late spring of 1897 and was driven about for a considerable period, chiefly for exhibition. The machine was experimental and it was a distinct advance, but because of the defective carburetion and the inability to always secure proper traction with the steel tired wheels, it was not continued in service.

This was not the first power wagon owned by this company. In the winter of 1895-6 Mr. Shepard, who was enthused with the performances of some of the earlier experiments with motor vehicles, had a steam power plant installed in a two-horse express wagon. This machine was used for about three months with some success. It was not a practical construction, however, the power practically wrecking the wheels, so Mr. Shepard decided to have a wagon built that would be the better adapted for the service.

Mr. Baldwin was at that time superintendent for the Cruickshank company. This concern was noted for the quality of steam engines it built and it was naturally to an an expert that Mr. Shepard took his proposition. Mr. Baldwin designed and superintended the building and installation of the steam plant. He drove the steam wagon for a considerable period and, with his experience, was the logical man for the development of the real industrial transport.



Mr. Shepard wanted the wagon for business purposes and he believed that steam did not offer greater possibilities than did gasoline. He wanted to have his wagon driven by a gasoline motor and proposed that Mr. Baldwin build it. Mr. Baldwin had an abundance of steam experience and was a skilled mechanic whose speciality was experimental work. Accordingly he undertook the job. The work was extended over a considerable period because of experiment and Mr. Baldwin designed an engine and transmission, invented or adapted an ignition system, and turned out a wagon that in general appearance compares favorably with those of today.

It was accepted by Mr. Shepard that wagon construction was no experiment, but he wanted a power plant, and it was toward the development of this agent for propulsion that his endeavors were chiefly directed. The wagon was intended for furniture delivery and the order for the body was given a western body builder. The running gear of the wagon was ordered nearer home, this being to specifications calling for heavier axles, springs, wheels, and other components.

The most important subject with Mr. Baldwin was the motor. It was necessary to install the power plant and all the mechanism below the floor of the body and to insure clearance a horizontal engine was imperative. A compact plant and minimum weight were essential factors. To incorporate these Mr. Baldwin decided to build a two-cylinder four-cycle double-impulse motor that would produce about 25 horsepower. This motor was novel in every sense and was found to be efficient despite the poor carburetion.

The cylinders were designed with liberal water-cooling space, there being about a .375-inch inner wall, an inch water space and a .25-inch outer wall. The cylinder was about 10.5 inches in diameter for nine inches of the length with a bore of 8.5 inches and then the cylinder was contracted to a diameter of 7.5 inches with a bore of five inches. The walls were not contracted at right angles but at an angle of 75 degrees with the walls. The cylinder head was cast integral and this was coned with the lines of the cone rising at an angle of 15 degrees with reference to the cylinder diameter. The angle of the cone coincided with the angle in the cylinder walls.

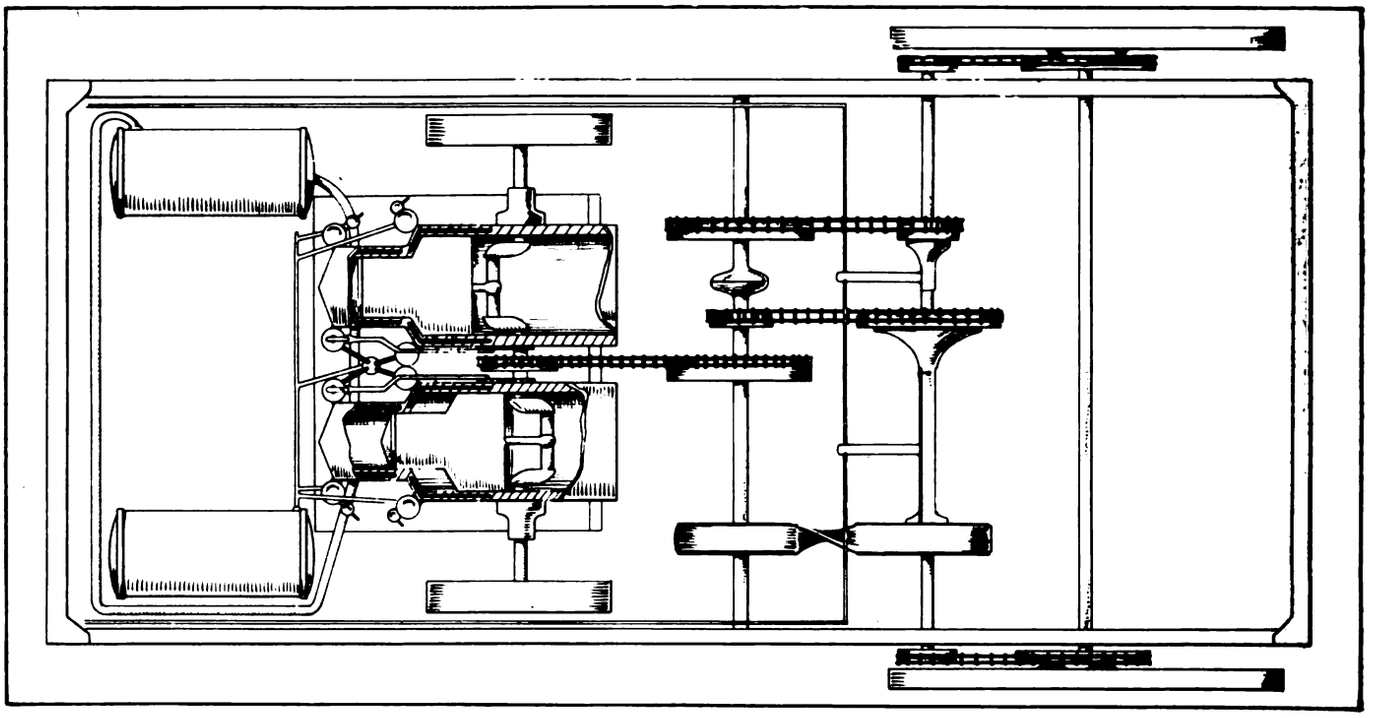
This gave a construction that, with the cylinder fitting both bores closely, had in the concentric or larger combustion chamber exactly the same area as the smaller or upper combustion chamber, and the coned walls and head were followed by the walls of the piston, this affording a strength that permitted a saving of about 40 per cent. in weight of

America's First Industrial Power Wagon, with Novel Power Plant, Built by L. F. N. Baldwin to Order of John Shepard, Jr., and Fitted with a Street Car Fender.

metal. The angularity of the piston heads was not such as to cause loss of power by a diversion of the direct expansive force. This entailed the placing of the wristpin in the extreme top of the piston and an extremely long piston rod was used, for the length of stroke for each section of the piston was six inches.

The construction necessitated two admission and two exhaust valves for each cylinder, the admission valves being so placed that they were between the cylinders when the motor was set up, and the exhaust valves were on the outer sides. The valves were mechanically operated by pushrods actuated by a camshaft driven by the crankshaft with conventional half time gears, but the admission valves were unique in that they each contained a carbureting device. The ignition was by hot tube, this being regarded as more dependable than any other method the vogue. The admission valves were bolted to bosses on the sides of the cylinders and to these the gasoline was piped from the tank. There was a float chamber with a float and a needle valve to regulate the flow of kerosene and from this an outlet through a spray nozzle into a mixing chamber,

Digitized by Google



whence the fuel was drawn into the cylinder. While it was possible to regulate the fuel the air intake was fixed and could not be changed, which is a sufficient reason to account for the indifferent carburetion.

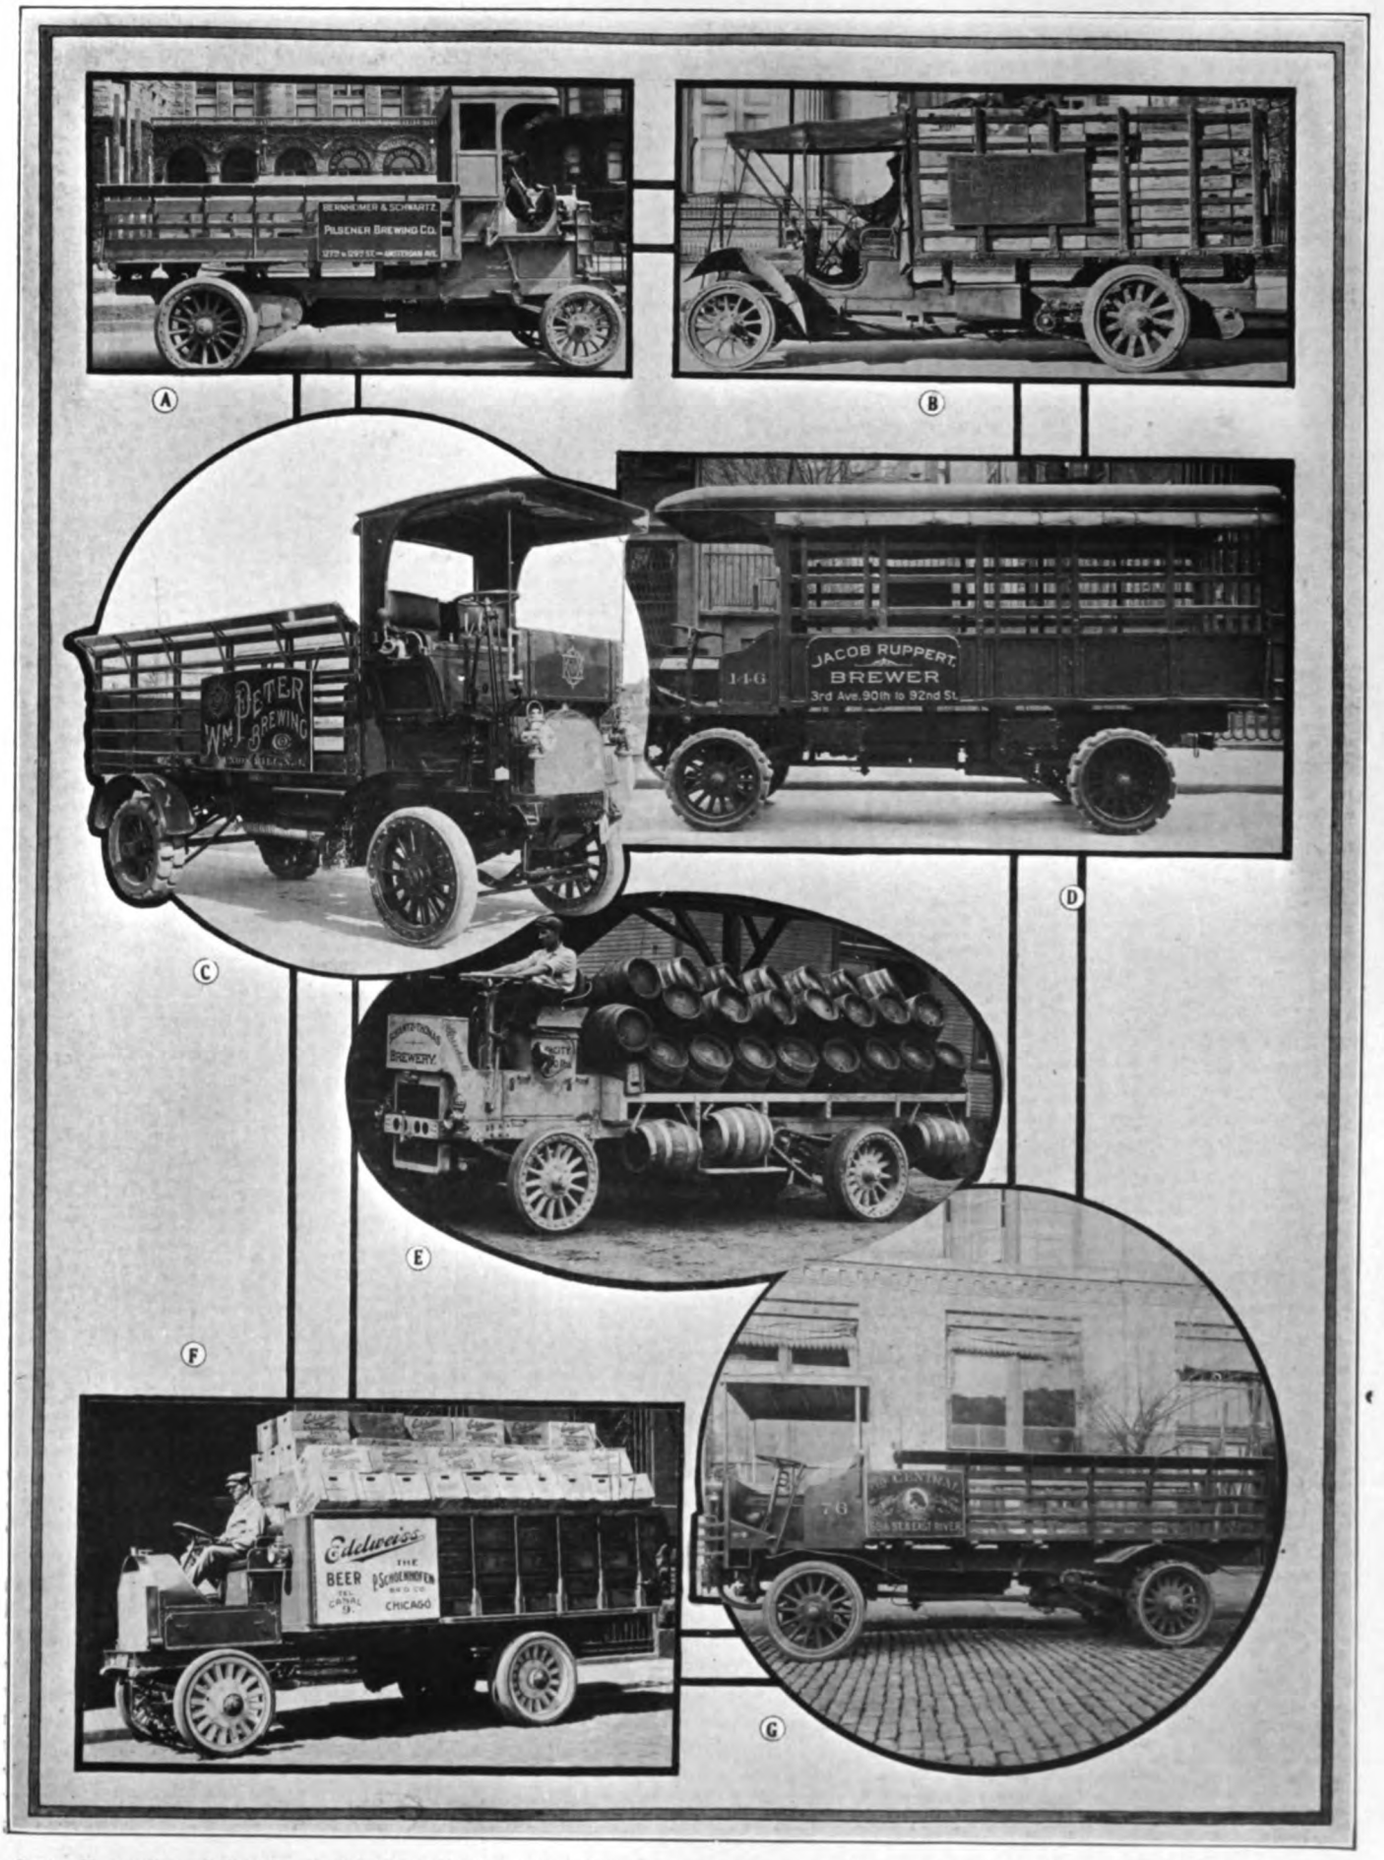
The ignition tubes were heated by two primus burners supplied with gasoline from a two-gallon tank by air pressure feed, this being sufficient to last a full day. The tubes were so installed that the pairs for each upper and lower combustion chamber were heated by a single burner.

The motor and the auxiliaries were enclosed in an iron box bolted to the floor of the body. Extending back from the centre of the crankshaft a chain was run. There was a flywheel at either end of the crankshaft, one wheel being shown in the accompanying illustration. The chain from the crankshaft drove a sprocket wheel on a second shaft mounted back of the engine case. This sprocket wheel contained the differential. On this shaft was carried at the left side of the sprocket a pulley six inches in width. At the right side were two sprockets of differing size. Obviously with the engine in motion this shaft was continuously driven by the chain running on the centre sprocket.

reverse with reference to a constant engine speed, and a variance of all three by varying the engine revolutions. From the jackshaft, drive chains extended to sprockets bolted on to the rear wheels. The chains were 1.25-inch pitch, of the type then used for farming machinery, and these were faulty in that they lacked strength and were frequently broken, necessitating delay for repair. The control of the wagon was by a wheel at the top of an upright shaft mounted in front of the driver's seat and by a worm engaging with a fifth wheel on the forward axle.

As will be evident from the description of the carbureting admission valves the supply of fuel was variable, but the flow of air was constant and the fuel feed was regulated from the driver's seat by a lever. At one side of the engine case was carried a fuel tank with about 25 gallons capacity, and at the other side was the water tank of 20 gallons capacity, this serving to radiate the heat. The water tank was of large size, for there was no radiation other than by convection from this tank. No other method for cooling was provided. The floor of the body was removable above the engine to give access for repair or adjustment.

Sketch Giving Approximation of the Two-Cylinder Double-Impulse Motor Power Plant and the Transmission Employed in the Baldwin-Designed Furniture Van Built for John Shepard, Jr., at Providence in 1896-7.



The two sprockets at the right side of the shaft carried chains which were extended to the jackshaft. This jackshaft was much the same as are all shafts of this type in cars of today, having sprockets for the final drive chains at either end. But it differed in that it carried three standard Brown & Sharpe friction pulleys. Two of these at the right side carried sprockets lined with the two sprockets on the first or layshaft, the sprockets being so arranged that the smaller on the first shaft drove the larger on the jackshaft, this being the low speed, and the other two, with reversed proportions, giving the high speed. The six-inch pulley at the left side of the shaft was driven in reverse by a six-inch crossed belt. The friction pulleys were all driven loose on the jackshaft until a speed was desired, when either the low speed or the reverse pulley clutch was engaged by one lever situated at the driver's seat, or the high speed clutch by another lever, and the pulley became fixed and the jackshaft was driven until the clutch was disengaged.

It will be seen that this gave high and low speed and

The engine was designed to give about 25 horsepower, and at times this power was realized, but at other times it was very much lower, much depending upon the carburetion. The pressure in the combustion chambers was low from the fact that hot tube ignition was used and this was also a factor in power. The accompanying illustration shows the wagon equipped with a fender, this equipment being installed by Mr. Shepard, who was then president of the Providence Car Fender Company, and who desired to exploit this device as well as to afford a protection against accident. This was, so far as is known, the first, and perhaps the only, machine ever fitted with such fenders.

The speed of the wagon was normally about 10 miles an hour, but it was possible to vary the speed by changing the sprockets. The wheels were fitted with steel tires and with these on gradients when the roadway was wet, or on wet paving, it was impossible to obtain traction. The engine had power enough to spin the wheels indefinitely, but the wagon was not heavy enough to give anchorage for initial propulsion, though the weight was fully 3000 pounds. The

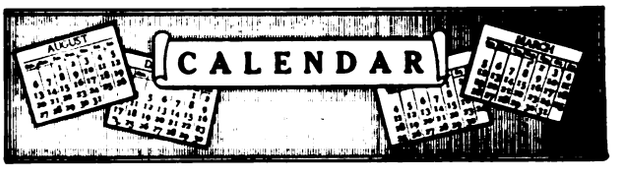
Some Examples of Trucks in Brewery Delivery Service: A, Sampson; B, Saurer; C, Mack; D, Hewitt; E, Speedwell; F, Old Reliable; H, Hewitt.

Digitized by Google

weight of the power plant was approximately 1900 pounds with the tanks filled. The body capacity was large, the wagon being designed to carry 20 complete bedsteads, with the head and footboards placed across the load space instead of lengthwise.

After the wagon had been used for several months and its limitations had been established, largely from the character of tires and the carburetion, and not from any other mechanical fault, it was laid up and later dismantled, the body now being in existence. While the design was crude and wholly experimental many of the ideas incorporated in it have been demonstrated to have practical value.

In comparison with this first power wagon, it will prove of interest to note the progress made in the construction and application of the industrial transport. To those who have followed the situation in the industry, there may be little need for comment upon the degree of perfection which has been attained. It is sufficient to indicate that it was the recognition of the immense possibilities for service in this type of vehicle, as demonstrated by Mr. Shepard in his determination to secure if possible a satisfactory mechanical conveyance, which has done much to overcome some of the prejudices which have made themselves manifest.



There still remains much of that adherence to custom or habit, continuing what is known to be inimical to every business principle and to every policy, because of unwillingness to take the initiative or to follow the lead of another. But there are certain lines in which endeavor has been made to meet the new conditions, and where there have been many dsirous of following the example which brought about the production of this first commercial motor vehicle.

There are few classes of service in which there is stronger demand for unfailing efficiency than in brewery delivery. In this field, the loads are heavy, the hauls short, much of the travel is on paving, and the deterioration is proportionate to the use. It is recognized that the cost of delivery bears a different relation between the motor truck and the animal conveyance than in some other lines of business. Service, efficient and regular, is the chief aim, although economy is to be considered.

It follows that the motor vehicles which have been used with success in brewery delivery represent at least one of the most satisfactory examples of the best standard practise in modern commercial car construction. The accompanying illustrations show trucks which have seen more or less service in this field in all parts of the country, some in large cities and others in smaller towns. They will furnish ample means of bringing forcibly to mind the splendid progress that has been brought about since Mr. Baldwin's initial attempt to produce an industrial power wagon.

MANY TIRES EXPORTED.

That American made tires are gaining in popularity throughout the world is shown by the large increase in exports during the past year. Tires to the value of $177,210 were exported during the month of November, 1911. Those of the same month in 1910 amounted to $150,214. The export trade for 11 months ending November last, totaled $2,257,727. A comparison with 1910 is not possible as previous to July of that year the government did not list tires separately. The United States Tire Company, New York City, is now sending large consignments monthly to South American ports and also has a flourishing trade in South Africa. The company will take steps to still further increase its foreign business during 1912, establishing branches wherever practical.

FACTORS IN TIRE EFFICIENCY.

The Motz Tire & Rubber Company, Akron, O., maker of Motz solid and cushion tires, is issuing an interesting booklet entitled, "Multiplying Truck Efficiency." The contents deals with the various tire problems in a practical manner and the pertinent facts are illustrated by half-tone photographs. The commercial and pleasure vehicle types are incorporated.

'VARSITY MEN AND TIRE MAKING.

It is interesting to note the large number of college graduates employed in connection with the automobile industry. According to W. D. Shilts, manager of salesmen of the Goodyear Tire & Rubber Company, Akron, O., many of the leading colleges are represented in the experimental and other departments of the company. Goodyear university men could, it is stated, form a football eleven that would include names very well known on the gridiron.

ELIMINATING DEAD MILEAGE BY TELEPHONE.

ELIMINATION of dead mileage is a proposition which interests taxicab companies throughout the entire country. While other items undoubtedly enter into the problem of making the taxicab business a paying venture in American cities, some method must be adopted to minimize the number of return trips without fares if the maximum profit is to result. Various plans have been tried in a number of localities, but the satisfactory solution appears difficult to find.

Pittsburg Taxicab Driver Calling Up Central Dispatching Station from Suburban Telephone.

It will be remembered that something over a year ago two or three of the larger taxicab companies in New York City combined forces in an effort to reduce the dead mileage. In this case, dispatching stations were maintained in what is termed the uptown and downtown sections of the city, and when one of the cabs in the downtown section, for example, delivered a fare in the uptown section the driver reported to the nearest uptown station, to which he was attached until occasion might call for his being dispatched to the downtown section again. Under this plan it was necessary to readjust the number of cabs in the respective sections from time to time. The plan was expected to minimize the dead mileage in an appreciable degree, and a later announcement seemed to indicate that such had been the case.

However, many conditions enter into the subject in New York City and while some of these apply as well in other centres, some do not. The situation with respect to dead mileage varies materially in different cities. The topography of the city is an important factor, and the relation of the business to the resident districts quite as much so. Moreover, the situation varies during certain hours of the day, a majority of the traffic being in one direction at one period and entirely the opposite at another, for instance.

Even this condition does not apply to all cities alike. In some centres there is a decided demand for taxicabs during the afternoon and evening and very little if any in the morning. In at least one city a plan was adopted in which a reduction of 33.3 per cent. was granted for taxicab service during the forenoon. It may be stated at once that the scheme proved a decided failure, and with reason.

It costs money to operate taxicabs. If the operation of the vehicle on dead mileage represents a loss, operation at less than cost also represents a loss, and it is possible to have dead mileage even when cut rates are offered, in which case there is a double loss. In addition, it is difficult to make the public understand why it should cost more for a ride in the afternoon than in the morning. As a matter of fact it should not and no taxicab company can afford to operate cars at one time for less money than at another. Obviously some other method must be found for the elimination of dead mileage, since this scheme by no means takes care of the original problem, but creates a new one quite as difficult to solve as the first.

A specific attempt to eliminate dead mileage may be cited in the case of the Pittsburg Taxicab Company, Pittsburg, Penn., which has asked the Bell Telephone Company of that city to assist it in the matter. The scheme has been tried out for the past three months in an experimental way, and has proven so satisfactory that it is to be extended throughout the city.

The Pittsburg Taxicab Company has been organized about 2.5 years, and its experience has been such as to indicate that the average cost of haulage by taxicab in that city is 31 cents a mile. It follows that every mile of dead mileage means 31 cents on the wrong side of the ledger. However, the topography of Pittsburg is such that long money-losing trips practically are eliminated.

An accompanying diagram sets forth this situation. Pittsburg may be described as three towns in one, east end, downtown and north side. Most of the hauls are confined to each locality, and 21 dispatching stations are maintained as indicated by the map. The central station of the company is in the east end. One of the dispatching stations is at Rittenhouse, one at the Pittsburg Athletic Club, another at the Hotel Schenley, and the remainder in the down town and north side sections.

The east end, being the residential section, no difficulty in dispatching is experienced. Calls naturally are sent to the company's office and garage, which is utilized as the centre of this section, but it was in this part of the city that the largest number of long hauls without passengers

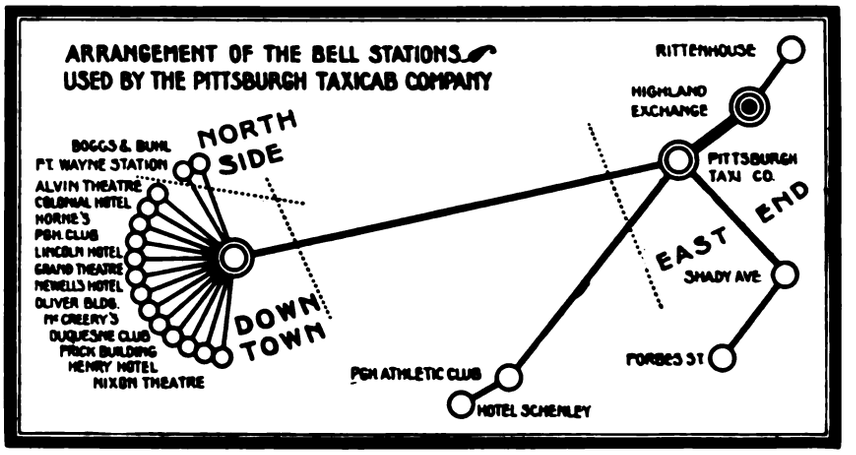

Diagram Indicating Location of Dispatching and Telephone Stations of Pittsburg Taxicab Company.

Digitized by Google

occurred. The company decided that the difficulty arose from inability to signal cabs in this residential section.

The telephone company was called into conference, with the result that a Western Union police telephone was placed on a pole at Shady and Northumberland avenues, and another at Murray and Forbes streets. These intersections are quite a distance from the garage and Rittenhouse stations, as will be noted on the map. Each driver was given a key and instructed to make stops at these telephone stations immediately after depositing his fare. If his services were needed in the immediate neighborhood he was dispatched accordingly.

As has been stated, the new system has been in operation for three months, and the results from these two boxes indicates the practicability of installing others throughout the entire city. When the plan is fully worked out it will be possible to have the driver stop at each box on his way back to the nearest dispatching station, and the dispatcher at the private central telephone station of the company will be able to direct him to any fare which may have called in the interim. Manager John W. Weibley of the Pittsburg Taxicab Company anticipates that it will be possible to handle at least 25 more calls during the busy hours under this plan with the same equipment, and that the dead mileage will be reduced to a minimum. Other cities will watch the further experiment with decided interest.

ALCO CREATES NON-STOP RECORD.

What is claimed to be a world's non-stop truck record was established recently by an Alco 3.5-ton truck, made by the American Locomotive Company of New York City. The machine, which is shown in the accompanying illustration, was in constant service for 336 hours without stopping the motor. Originally it was intended to operate the car but a week, but at the end of that time it was decided to continue to better the record of 168 hours established a year ago.

Alco 3.5-Ton Truck Which Participated in a Non-Stop Service for the Adams Express Company of Philadelphia—The Motor Was Run Continuously During the Test.

The machine had been in service over six weeks when it was started to aid the Adams Express Company in handling its Christmas business. Unusually severe weather conditions were experienced but the power wagon adhered to the schedule despite the snow and ice, and made night deliveries to the residential sections of a number of New Jersey cities.

The car performed varied duties and transported on the average about 35,510 pounds of merchandise, travelled approximately 66 miles, made 14 trips and 92 stops daily. The record mileage for one day was 86 and the largest number of trips 22. The largest number of stops made in one day was 104. During the two weeks the automobile covered 922 miles, made 198 trips and 1284 stops, and hauled 441,136 pounds. An average of one gallon of gasoline to an hour of service was maintained. It replaced five two-horse teams and four men accomplished the work assigned to 10 under the horse drawn equipment.

SAYS HORSE WILL NOT BE EXTINCT.

"If every automobile factory in the United States were to double its present capacity, and every machine was a commercial vehicle there would not be enough to take care of the increase alone in our commerce at the present rate of growth, if the government statistics can be taken as a guide," says W. E. Wright, vice president and general manager of the Knox Automobile Company, Springfield, Mass. "The year book of the Department of Agriculture shows a wonderful increase in horse stock. In 1900 there were 15,000,000 horses in the United States and 10 years later, or in 1910, there were 24,000,000 showing a gain of 60 per cent.

"Horses have also increased in value. In 1900 the estimated value of animals utilized on farms was $44 a head, with a steady rise, interrupted only by the panic of 1907. These values increased steadily, until in 1910 the average price was $108, representing a gain of nearly 150 per cent. The value of horses and mules in this country 10 years ago was about $815,000,000, while today it exceeds $3,000,000,000. This evidently does not bear out the assertions made frequently that in 10 years the horse will be extinct, nor does it signify that the manufacture of automobiles is being overdone.

"At the present rate of increase in our commerce, in 1920 it would take nearly 40,000,000 horses to supply the demand. If the horse is to be superseded by trucks or tractors it would take, allowing that one truck will do the work of six horses, 7,000,000 machines, the life of these being estimated at five years. It would require a production of 1,400,000 trucks a year to supersede the horse entirely in 10 years."

FISHBACK COMPANY SEEKS LOCATION.

The Fishback Motor Company, Newark, N. J., which was incorporated recently for $3,000,000, is seeking a factory site, according to a communication received by business men in Youngstown, O., and other places. It is stated that the company proposes to market a line of low priced cars and wagons, and that it will require about six acres of land to accommodate its immediate needs.

MOTOR TRUCKS IN SHORT HAUL DELIVERY.

Knox Machines in the Service of the City Coal Company, Hartford, Conn., Show a Decided Economy When Contrasted with Animal Carts in Actual Use, Both in Haulage and in Labor, as Well as in Time.

By William W. Scott.

THE cost of any form of transportation is dependent upon the ratio of the total mileage for which revenue is received, provided, of course, that the market price for service is not below what will yield a fair margin of profit. It must be assumed, however, that any haulage enterprise must be reasonably profitable to continue. Many elements enter into expense. These factors are so numerous that it is doubtful that they are ever all recognized, and it may be that even a casual examination will reveal large possibilities for economy. But as practically every business is conducted with some regard to system it may be accepted that the methods employed are reasonably satisfactory.

Regarded purely as a commercial proposition every business man is willing and generally anxious to economize, yet there are many who hesitate to adopt what may appear to them to be experiment. It is needless to say that this apprehension as to results is inherent and many, until there is abundant demonstration, are not willing to employ what has been unquestionably productive with others. The reason for this may be realization that there are no two concerns with methods exactly alike, and yet it may be failure to understand the possibilities.

That in transportation there has been neglect of the exactness of accounting applied to other enterprises no one will deny. The absence of the information that such data would afford is perhaps one of the greatest obstacles encountered by those who study the utility of the power wagon, for generally its service must be contrasted with that of animal transports. It is only when the two classes of haulage are employed that it is possible to make comparison that is valuable, for then it must be evident that the conditions are as nearly at parity as can be conjectured or desired.

An experience that dates from May 6, 1911, with the service of the City Coal Company, Hartford, Conn., in which two Knox trucks are utilized with animal wagons and carts, is decidedly interesting in that it demonstrates there is practical economy in the short haul delivery made, a class of haulage that has always been assumed to minimize the advantage of the larger capacity and increased mobility of the motor truck. The first truck was of four tons capacity, the second, received Sept. 1, was a five-ton machine.

Knox Five-Ton Truck Loaded with Lime and Cement and Its Crew of Driver and Two Helpers.

Delivers From Top of Hill.

As no intelligent conception of the work accomplished can be realized without knowledge of the conditions in which the company transacts its business, it is necessary to state facts which relate to the delivery service in which the trucks are engaged. Hartford is on the west bank of the Connecticut river and on an eminence that slopes in every direction, but more pronouncedly toward the river. The yard of the City Coal Company is in Garden street, very close to the highest point in the city, and the coal is delivered at the yard by train. This coal is in turn sent out to customers. As the loaded carts are sent down hill and the return trips are without loads when the haulage would be hardest it is possible to send out more equal loads throughout the year than would be practical were the conditions reversed. As a mater of fact the company has an advantage in the site of its yard that is worth a great deal of money in the course of a year, and each year this is becoming more valuable.

Digitized by Google

To emphasize this it should be stated that the average load of coal carried during the two severe winter months and the three summer months when the temperature is excessive is from 65 to 85 per cent. of the weight hauled under more favorable conditions, as shown by the experience of similar concerns in other parts of the country. Hauling the loads down grade means quicker delivery, longer service for the horses, and generally increase of weight carried. The influence of these factors upon the general proposition is apparent, and it should be understood that this condition is decidedly advantageous to animal haulage.

Sells Coal and Building Material.

The business of the company, however, is not confined to coal, for it deals in lime, cement, brick and similar building material, which is distributed under the conditions stated with the same advantages. While the coal delivery is necessarily restricted to the city, or very nearly so, it is apparent that there is no limitation to the other division of the concern save the facilities for haulage.

The company has maintained a horse equipment that might be regarded as considerably less than the minimum requirements, supplementing this with hired horses and carts as occasion demanded. While this minimized the cost for equipment investment it somewhat increased the expense when animals and wagons were hired because of the profit naturally expected by the owners renting them. In its accounting the company did not, until the purchase of the trucks, make provision to ascertain precisely the cost of animal delivery, and while it has more carefully systematized its records the data has not been computed and arranged so that exact details may be stated. There are other elements that have not been as yet determined. For instance, the record of the horse delivery does not include the cost of investment, interest on the investment, insurance, depreciation, restoration, repair or maintenance, and does include the cost of food, shoeing and the Saturday pay roll. These items are to be supplied in completing the record for the year. With the trucks the five records maintained are insurance, labor, supplies, repairs, sundries, which are to be supplemented at the expiration of the year with the items of investment, interest on investment and depreciation.

Conditions Governing the Business.

For these reasons it is not possible to compile in tabular form what will effectually contrast the work accomplished by the two divisions of the service, nor is it possible to establish the exact cost. But it is entirely practical to make comparisons of the average haulage by the trucks with the maximum possibilities of the animal wagons, which does not by any means indicate the superiority of the former with respect to every detail.

Continuing the consideration of the company's business and its methods it may be stated that practically all the commodities it distributes are received by rail and stored at the yard. In connection with the yard is the stable where 14 horses are kept and these are used for hauling four single and five double-team carts. As to the investment these represent it should be stated that it is estimated that $1000 will purchase a pair of horses, cart, harness and other equipment, all first class. A single horse, wagon, harness, etc., will represent about $600. No provision is made for reserve of horses other than to hire what extra animals and carts and drivers are needed, the price for a double team, cart and man being $5 a day and for a single horse, wagon and man, $3.50 to $3.75. It will be seen that there is a profit made on these prices, but allowing $1 a day for the horses, 50 cents for the wagons and $2 for the man, the items are not excessive. It is estimated, however, that $1 a day an animal will provide for the stabling, feeding, shoeing and veterinary attention and other necessary expenses in connection with the maintenance of horse equipment.

Knox Five-Ton Truck Returning from the Delivery of a Load of Coal Carried in the Bags Shown on the Platform.

Digitized by Google

Horse Equipment and Its Work.

The City Coal Company, in systematizing its distribution, loads coal either in bags or loose in chute wagons. The lime is usually in barrels and the cement in barrels or sacks. The proportion of the coal delivered by the chute wagons is not large because of the fact that a comparatively small number of residences are arranged for chute delivery. Coal sent to shops and factories, however, is often by chute wagons. The mileage of the chute wagon, which usually carries full loads, is estimated at 14.7 miles daily. The bag wagons average 17.1 miles daily. This gives weekly mileage of 88.2 and 102.6, respectively. The wagons are sent out with four loads each day, there being one long haul and one short haul each half-day, this being found the better manner of economizing time. Allowing 24 loads a week for each class of wagon it will be seen that the average round-trip mileage for the chute wagon is 3.675, and for the bag wagon 4.275. To expedite delivery and save time a driver and a helper is always sent with either single wagon or team cart and sometimes a driver and two helpers with the larger loads. The maximum load for the single wagon is 3000 pounds and for the team cart 6000 pounds, which figures are rather less than the average loads in other localities, even where the load haulage is heavy. This statement indicates the conditions under which the business of the company was developed.

Turn to Trucks as Economy.

The experience during the summer and autumn of 1910 and the winter of 1910-11 and the expansion of the business were such that the company found it necessary to consider additional delivery facilities. The results of horse haulage were not adequate because the custom for building material was increasing and delivery was so frequently outside the city that the conditions were at times diametrically different when compared with the coal delivery. To send a load of lime or cement to a point five miles distant meant a half-day at least, increasing the delivery cost and lessening the profit. To go nine or 10 miles meant a full day, or nearly so, for a team, cart and two men, and not more than three tons could be hauled. As the market expanded there was increased difficulty of delivery and greater cost.

In considering haulage, taking the standards of a capacity load, a given distance and a stated time for a work the following elements of economy are found:

Capacity Load	Given Distance	Less Time
Capacity Load	Longer Distance	Stated Time
Larger Load	Given Distance	Stated Time
Larger Load	Given Distance	Less Time
Larger Load	Longer Distance	Stated Time
Larger Load	Longer Distance	Less Time

Any one of these factors would be a reason for making such change as would economize expense, and when two or all three could be combined without possibility of failure of results or loss it would appear there could be no doubt as to the decision of a progressive business man.

Knox Four-Ton Truck with Wood Body Adapted for Coal Delivery, It Being Fitted with Rear Chute for Quick Discharge.

Model R Knox and Its Service.

Having had experience with pleasure automobiles and with a practical knowledge of these machines the members of the company decided to purchase a four-ton Knox truck. This was the Model R-16 with wheelbase of 149 inches, 40 horsepower motor, maximum speed of 12 miles an hour, and fitted with a body hoist and a wood body with end gate discharge and chute. A driver employed by the company was sent to Springfield, Mass., to the Knox factory, where he was fully instructed as to driving and caring for the machine. When the truck was delivered he drove it to Hartford and since that time it has been in his care. It was believed best to have a fully competent and trustworthy driver and the result has justified the decision.

The truck was placed in service May 6, and to noon

Digitized by Google

February 22 it had been driven 6402.8 miles, as shown by the odometer, and had averaged 156.1 miles weekly during that period. This is about 26 miles daily, or 11.3 miles more than the average mileage for the animal-drawn chute wagon. Considering mileage only it has been driven approximately 75 per cent. further daily than the average horse team and cart, and has a load capacity of four tons as against three, or 33 per cent. more. The reason why this mileage is no greater is that the company started the truck at the same work the wagons are employed for, it being frequently sent out with a load of bag coal, for instance, to make four or five deliveries during a single trip. Of course with the driver and two helpers the distribution is quickly made.

Instances of Excess Work.

The long hauls were made by the truck and of course the greater number of these were with lime and cement. It was utilized for emergency deliveries, which were frequent, because many contractors have their materials sent to them daily, instead of storing a considerable quantity. The reason this plan is adopted is to prevent exposure of lime or cement in the absence of shelter, for rain would cause decided loss. With haulage of this kind the truck could supply sufficient material to the builders that their work might not be delayed, this being a condition that attracted patronage, while with the coal delivery it had equal superiority as compared with animal carts. Without the truck prospective orders outside of the city were sometimes refused because of the cost of delivery, but it was found that a radius of a dozen miles or more could be served with the truck quite as well as the patronage of the city could be met with the old service. The truck speed was governed to 12 miles an hour and care was taken to keep the loads as close to the capacity of the machine as possible. Two initial expenses were $152.75 for insurance and $7 for the registration and driver's license fees, but later the insurance was increased in amount and the registration cost was doubled by an amendment to the state law.

In keeping the expense of the truck under the general head of supplies were entered the items of labor, supplies (gasoline, oil, grease, waste, etc.), repairs and sundries. It was believed that the fixed charges could be learned with exactness at the end of the year, which would serve better than to estimate them. For this reason there is no manner of showing difference between estimated and actual items of expense, which would be a decidedly interesting result.

Second Truck Four Months Later.

After the truck was placed in service it was found so satisfactory that, with the expansion of the business through the additional facilities, it was believed necessary to make further improvement, and this impelled the order for the second truck, which was delivered Sept. 1.

With the receipt of the second machine the item of insurance was somewhat increased. It was also necessary to license both trucks, and this cost $19 and $23 respectively for the four and five-ton vehicles. Beginning with Sept. 1 a new account was inaugurated in which the expenses for the machines were divided for the items of labor, repairs and sundries, and supplies (gasoline, etc.), combined for the two, although the purchases for each truck may be separated later.

While the greater part of the construction work may be assumed to be during the six months beginning May 1 of each year it is begun as early as April 1 and it is continued until nearly if not quite to the end of the year. The family supplies of coal are usually delivered during the late spring and summer, but the shop and mill deliveries are generally to contract and with quantities not greatly varying each week. The last mentioned class of custom and the small and emergency family orders are delivered throughout the winter. From this it will be seen that the

City Coal Company's First Delivery Truck with the Body Elevated to Show the Chassis Equipment.

Digitized by Google

building material trade is in least volume during the severe months of winter, and that coal purchasing is not extremely heavy, although the long period of low temperatures since the beginning of the year has caused a heavier business for 1912 than is ordinarily expected.

Week's Work Under Good Conditions.

To illustrate the work that each machine has accomplished the following records are given:

Four-Ton Truck, Oct. 2-7, Inclusive.

Weight, Pounds	Loads	Coal, Pounds	Lime and Cement, Pounds
36,400	5	13,800	22,600
49,500	7	8,000	41,500
24,900	3	22,900	2,000
72,290	9	72,290	
44,420	5	26,520	17,900
59,940	7	59,940	
287,450	36	203,450	84,000

Five-Ton Truck, Oct. 2-7, Inclusive.

Weight, Pounds	Loads	Coal, Pounds	Lime and Cement, Pounds
55,000	6	24,000	31,000
58,100	6	13,000	45,100
44,710	5	22,010	22,700
51,000	5	51,000	
40,300	4	20,000	20,300
55,500	6	24,000	31,500
304,610	32	154,010	150,600

Analyzing these results the following is found:

Four-Ton Truck, Oct. 2-7.

Trips or loads	36
Daily mileage	..
Round trip average mileage	..
Average load, pounds	7985

This is work equal to 48 full loads of 6000 pounds each with a two-horse team and cart, or the work for 12 full days of such equipment, making four trips daily. The three men on the truck were employed the equivalent of 18 full days, and two men on one cart for 12 days would equal 24 days for one man. Thus the truck did the work of two horse outfits and there was the saving of the pay of one man for six days.

Five-Ton Truck, Oct. 2-7.

Trips or loads	32
Daily mileage	..
Round trip average mileage	..
Average load, pounds	9831.5

This is work equal to 51 full loads of 6000 pounds each with a two-horse team and cart, or the work for 12.75 days for such equipment, making four trips daily. The three men on the truck were employed the equivalent of 18 full days, and the two men on a cart for 12.75 days would equal 25.5 days, for one man. The truck in six days did the work two horses would require 12.75 days to perform and the labor was 18 days' work for one man for the truck, equal to 25.5 days with the animal delivery.

Four-Ton Truck, Jan. 9, 10, 11, 12, 13, 15.

Weight, Pounds	Loads	Coal, Pounds	Lime and Cement, Pounds	Mileage
70,930	8	70,930		28.1
60,090	7	60,090		24.3
65,710	8	62,110	3,600	23.4
46,710	6	46,710		21.2
50,780	6	50,780		25.1
49,710	6	33,710	16,000	21.0
343,930	41	324,330	19,600	143.1

Five-Ton Truck, Jan. 16, 17, 18, 19, 20, 22.

Weight, Pounds	Loads	Coal, Pounds	Lime and Cement, Pounds	Mileage
42,000	5	34,000	8,000	26.0
58,750	6	54,000	4,750	24.8
33,200	5	33,200		26.2
37,500	5	37,500		22.4
41,600	5	25,000	16,600	28.7
39,850	5	10,100	29,750	22.7
252,900	31	193,800	59,100	150.8

Making similar analysis the following is found:

Four-Ton Truck, January.

Trips or loads	41
Daily mileage	23.5
Round trip average mileage	3.490
Average load, pounds	8398.5

This is work equal to 58 full loads of 6000 pounds each with a two-horse team and cart, or the work for 14.5 days for such equipment, making four trips daily. The three men on the truck were employed the equivalent of 16 full days, and two men on the animal cart would be the equivalent of 29 days. The truck did the work of two and five-twelfths horse outfits and there was the saving of the pay of one man for 11 days.

Five-Ton Truck, January.

Trips or loads	31
Daily mileage	25.15
Round trip average mileage	4.84
Average load, pounds	8158

This is work equal to 44 full loads of 6000 pounds each with a two-horse team and cart, or the work for 11 days for such equipment, making four trips daily. The three men on the truck were employed the equivalent of 18 full days and two men on the cart would be the equivalent of 22 days for one man. The truck did the work of one and five-sixths horse outfits and there was a saving of the pay of one man for four days.

Comparison of Combined Work.

Combining the work of the trucks for the two periods instanced gives the following:

October period: Work equal to 99 full loads of 6000 pounds each with a two-horse team and cart, or the work for 24.75 days for such equipment, making four trips daily. The men on the trucks were employed the equivalent of 36 full working days. Were the horse carts used the labor would have been equivalent to 49.5 full days for a man. The trucks did the work of two and one-eighth horse outfits each and there was a saving of one man for 13.5 days.

January period: Work equal to 102 full loads of 6000 pounds each with a two-horse team and cart, or the work for 25.5 days for such equipment, making four trips daily. The men on the trucks were employed the equivalent of 36 working days for a single man. Were horses used the labor would have been equivalent to 51 full working days for a man. The trucks did the work of two and seven-twenty-fourths horse outfits each and there was a saving of one man's labor for 15 days.

Cost of Operating Motor Trucks.

Now as to the cost of the trucks. The items of investment, interest, depreciation, insurance, have not been considered. The price of the four-ton Knox chassis is $4000 and the five-ton chassis costs $4500. To these must be added the expense for the body equipment and the delivery. The insurance will average about $175 annually. The expected depreciation is 20 per cent. These will not vary greatly.

The actual cost for using the trucks has been as follows:

Knox Four-Ton Truck.

Date	Labor	Supplies	Repairs	Sundries
May 6 to Sept. 1....	$434.54	$128.13	$ 5.55	$ 4.20
Sept. 1 to Feb. 1....	542.17	*113.57	79.30	**29.75
	$976.71	$241.70	$84.85	$33.95

Knox Five-Ton Truck.

Sept. 1 to Feb. 1....	$687.41	*$113.57	$34.92	***$29.75

*Supplies expense equally divided between the trucks. **$19 for registration and driver's license. ***$23 for registration and driver's license.

Taking up the analysis further it is found that the four-ton truck was in service from May 6 to Feb. 22, when the mileage record was taken, 246 working days and for that

Digitized by Google

time the daily average was 26.30, and a weekly average of 157.80, against an average of 102.6 miles weekly for a bag wagon and 88.2 for a chute wagon. The truck compares best with the chute wagon. For a period of 147 days the five-ton truck had an average mileage record of 21.22 and a weekly average of 127.32. Taking the cost of supplies for each truck for the entire period to Feb. 1 the cost was four cents a mile for the four-ton truck and 4.2 cents a mile for the five-ton truck.

The total cost of the four-ton truck for labor, supplies, repairs and sundries, which included the registration and the driver's licenses, was $1337.21 during the period specified, and this was an average of $5.75 a day. The average for the five-ton truck was $6.76, but it will be noted that the charges for labor to the five-ton truck are considerably larger than for the older machine.

In the figures that have been presented it must not be assumed that these were selected with a view of making the best showing that could be made. As a matter of fact the four-ton truck in one week in October had a mileage of 187 miles and carried 281,490 pounds of freight. The January record is probably as good as any that might be noted, though it has been materially exceeded in mileage.

Relative to the five-ton truck: It has a record of 149.9 miles in a week in October, and carrying 313,610 pounds of freight, which exceeds the first period stated, and in a week in January with a mileage of 105.2 miles it delivered 310,070 pounds of freight, or nearly 30 tons more than during the week specified. This will evidence that the quotations have been at least sufficiently economized to be regarded as conservative.

Capacity Loads for Animal Carts.

It will be noted that in every comparison made the work of the trucks has been placed against capacity loads for animal carts, and obviously it is not possible always to send out a full load. Considering this fact it will be understood that the full value of the trucks does not appear on the face of the statements concerning them. There has been no instance where the trucks have not been, with the loads carried, at least the equal of two two-horse cart outfits, and the mileage record shows that they travelled a distance approximately 50 per cent. more. This fact is also important.

One of the great advantages of the trucks is in serving the increased territory. To illustrate: There is one customer at Glastonbury, eight miles from the yard and with a good road the entire distance. A two-horse team will haul three tons to this customer and return to the yard in six hours, but this is practically a day's work for the animals and they can be used but little more, if any, the same day. The five-ton truck will take from five to six tons to the same customer and return in 2.5 hours.

Considering this service on the basis of hauling a ton eight miles, it may be shown as follows:

	Weight Carried	Miles	Time
Two-horse cart	6,000 pounds	8	6 hours
Five-ton truck	12,000 pounds	8	2.5 hours
Equal To			
Two-horse cart	2,000 pounds	8	1.5 hours
Five-ton truck	2,000 pounds	8	25 minutes

In this it will be seen that the truck will carry one ton and deliver it in about 21 per cent. of the time required by the animal cart, assuming the facts stated. With the load at 10,000 pounds the time is increased to 30 minutes for the ton or 25 per cent. of the time required by the horses. In this it will be understood that there is not only the saving of the time of the truck but of the three men who man it, a very material item in the expense of maintaining a delivery system. This quality is emphasized because it has been shown that under the least favorable conditions the trucks are more than equal to two two-horse delivery outfits, while their superiority becomes more and more apparent as the haulage distance is increased.

The first truck is driven by the man who was instructed in its use at the Knox factory and the larger machine is handled by an experienced man who was hired to keep it in order and operative. The company has not yet attained the proportions that would seemingly justify it building a special garage and equipping it with facilities for specially maintaining its trucks, but it would seem that this would be a logical result, as it is probable that one or more trucks will be added this spring. The company has not been disappointed in the vehicles and the delivery has unquestionably been improved.

In connection with this statement the subject of tires is decidedly interesting, but it is not possible to give figures relative to this expense, despite the material mileage of each machine. According to the officials of the company the original shoes are on the four-ton truck and these appear to be not more than half worn. The statement was made with the mileage at 6042.8. There has been no decided wear evidenced on the shoes on the five-ton truck, which had at the same date been driven 3119.8 miles. Perhaps the tire experience has been unusual, but there is no question whatever that there has been a seemingly satisfactory service with a prospect of this continuing for a considerable period, at least.

AMEND MASSACHUSETTS BILL.

The opposition to the proposed Massachusetts bill to limit the weight and speed of commercial vehicles utilized in that state, apparently has had its effect upon the legislative committee as it practically has been agreed that the act shall be amended so that the weight limit shall be 12 tons instead of six. At the hearing, truck owners, dealers, etc., appeared in opposition to the measure. It was agreed to refer the bill to a sub-committee, the latter to meet a committee of truck users.

Regarding tires the protestants against the bill recommended an investigation by experts to obtain adequate data relative to the transportation of freight upon roads and bridges. Figures were submitted by an opponent of the measure, alleging the impractibility of equipping wagons with one inch of tire for each 800 pounds.

STEBBINS ASSIGNED TO NEW YORK.

H. S. Stebbins of the General Motors Truck Company, Detroit, has been assigned to New York as Eastern district manager of the company. The rapidly increasing business in this territory has made this move necessary and Mr. Stebbins will have charge of all interests, both in the development and the administration of the business. He is well known to the industry, especially with respect to transportation, having been for years the traffic manager of the leading railroads, and his experience in this as well as in the commercial car field eminently qualifies him for his new position. He has been traffic manager of the General Motors Truck Company for several years, which position he still retains in connection with his other duties.

SPECIALIZES IN DUMPING WAGONS.

Announcement is made from Harrisburg, Penn., that ground has been broken for a new motor truck factory, in which J. D. Hipple and C. C. Bennett will be interested. It is understood that the product will be of the heavy duty type, and that the company will specialize in vehicles for hauling and dumping coal, sand, building materials, etc.

Digitized by Google

CARING FOR THE COMMERCIAL VEHICLE.

THE ACCOMPANYING communication takes up a subject in which the owner of a commercial vehicle has a direct personal interest. The writer, Henry J. Barbour, has long been connected with the Avery Company, Peoria, Ill., which concern has been engaged in the manufacture of industrial transports and tractors for a number of years. The information contained therein is the result of a careful study of conditions which have been presented in the use of these vehicles in various sections of the country and covering a long period. Mr. Barbour therefore speaks with authority, and his consideration of the subject should prove of decided importance to the owner and operator of commercial motor vehicles.

Editor, MOTOR TRUCK,
Sir:

Motor trucks have become recognized as being no longer in the experimental stage. Every day we hear of firms who have discarded the old horse system and accepted the modern power wagon, both for light and heavy haulage, and of success in some new field, in the country as well as in the city. But seldom do we hear of the failure of the motor truck system, and if we do we are almost certain to find some other cause than the vehicle itself. Most manufacturers take great pride in the construction of their product. They try to put into it the best material suited for its special purpose. The machines are built and assembled under the most careful supervision. Men of ability and experience are employed, and after a car is finished it is given a final severe test on the road. Therefore it must be seen that if a machine "falls down" when it gets into active service, it generally is the fault of the man who is driving it.

Usually, the troubles of a motor truck can be traced to poor lubrication, lack of care for the essential parts of the machine, or careless and bad driving. Lubrication is the most important thing with any piece of machinery whose parts moving on one another create friction. It is not possible to eliminate friction entirely, but it can be reduced very materially. The purpose of a lubricant is to do this; to reduce sliding friction to a possible minimum, and it does this by supplying a thin film of viscous fluid between the bearing surfaces.

Generally speaking, there are three kinds of oil used on a motor truck. First, there is a comparatively light oil for the motor and bearings; second, a heavier or non-fluid oil for the gears and wheels, if the latter be fitted with roller bearings, and lastly, a hard oil or grease for the transmission and differential.

Beginning with the engine, we find that inside this cylinder oil is used. It is best to use the oil for which the car was designed, or that recommended by the manufacturer. There are at least half a dozen first class oils on the market, any one of which can be used without anxiety, but all cylinder oils must have the following characteristics:

They must be non-carbonizing; that is, they must not deposit a layer of carbon in the combustion chamber.

They must not become gummy. They must be of the greatest body or viscosity possible, yet permit a uniform feed all the time, regardless of the temperature.

They must be able to retain their normal body while in use, and must not turn into a thin or watery substance.

They must be "slippery" enough to allow all of the working parts to move smoothly, readily and easily.

They must never contain any gritty foreign matter, which will furrow the bearings.

Cylinder oil with these qualities certainly will not cause trouble. When running the engine, always see that the cylinder oil is at the correct height in the crankcase. If there be a circulation pump in the crankcase, it must be in good working order, otherwise the engine is liable to overheat, the piston to stick to the walls of the cylinder, and the result is a burned-out motor, which will have to be rebored, to become of any value.

Not long ago, we received a letter from a man who bought a truck, telling us that he had had great misfortune with his engine. It was his own fault, however. The man had driven 25 miles with a heavy three-ton load, starting with a very small amount of oil. The result was that after going up several sandy hills and traversing about three-quarters of the distance, he found the engine was overheated and there was hardly any lubricant in the crankcase.

Instead of stopping and sending ahead for oil he thought he could make the town, and started to do so. Within about two miles of his destination, he heard an awful crash, and jumping off he found that one of the connecting rods had burned off the crankshaft and had been shoved through the crankcase. The result was a heavy expenditure through his own carelessness. Engines are like people; they must be kept in condition if good work is expected of them.

The next thing to be considered is the oiling of all the small gearings, roller bearings and compression cups. These should be oiled twice a month with a heavy or semi-fluid oil, but not as hard as that used in the larger gearing. Like all oils, this should be free from any gritty matter, and must be able to stick to the gears. On all wheels and the other bearings there will be found oil cups. These should be filled at least once a week with this oil, and screwed down firmly after each trip, so that a new layer of oil is forced upon the bearings each time.

That a tremendous amount of energy is exerted in the heavier gears, such as the transmission and differential, is self-evident. It has been proved that close to half a million foot-pounds are exerted on every tooth of the transmission gears in one minute, when the truck is travelling at a rate of approximately 18 miles an hour. Think of it! A force on each little metal tooth, sufficient to raise 500,000 pounds one foot a minute!

Since this is true, the care and the oiling of the transmission and the differential can be seen to be very important. Without oil, the friction and heat would be terrible. Therefore, an oil of certain good qualities must be used. It must coat the working parts at all times, and absorb the friction. It must cling tenaciously to the gears, regardless of the heat or cold, yet at no time become gummy or resinous.

Another cause of failure in motor truck service, is that due to bad or careless driving and the abuse attending this upon the clutch, brake, chains and tires.

It is bad policy to allow everyone to drive a truck, because each individual drives a car in a little different manner, and the various methods of shifting gears in the transmission, for instance, causes them to wear out quickly. However, if one is careful to have the clutch pedal pushed entirely out, he will have no trouble with the changing of speeds. A great many drivers change speeds with the clutch partly disengaged and stripping the gears is the result. Then, sometimes drivers engage the clutch so quickly that there is a burst of momentum from the car that nearly tears off a tire.

If the clutch be in the habit of gripping, slipping or spinning, it should be attended to at once. Gripping is due to faulty mechanism, too tight spring tension or lack of oil. Slipping is not dangerous, but is the cause of much annoyance, and loss of time and power transmitted to the driving wheel. The causes either are insufficient spring tension or a greasy surface (if the clutch be leather faced.) In the first case, the spring can be tightened, but in the second, French chalk should be used to get rid of the grease. Spinning clutches are so called when the clutch driven shaft continues to revolve after the clutch is disengaged. It causes a series of blows on the teeth of the gears in the transmission, which is very destructive. Some manufacturers fit this member with a clutch brake. The clutch is a most important part of the truck and it should be considered as such. It should be examined and tested once or twice a month, and if it fail to do its duty should be adjusted immediately.

There is an old law in physics which reads something like this: "A body in motion tends to stay in motion; a body at rest tends to stay at rest." This is true of a motor truck. A vehicle in motion tends to stay in motion, and it will do so until stopped by friction, either the friction of its parts or applied friction. Applied friction is furnished by the brakes, and these to be of any value must be effective and dependable.

A large brake surface is desirable. No three-ton truck should have less than 450 square inches of brake surface. A light truck weighing 3000 pounds and running at the rate of 20 miles an hour exerts about 50,000 foot-pounds of energy. To stop this in five seconds means that from 14 to 15 horsepower must be absorbed by the brakes. Braking creates immense heat, and therefore, if the brake surface be small, the pressure a square inch is greater and the brakes are liable to "burn up." The larger the brake surface the less the pressure a square inch, and the less tendency to burn. It also might be said here, that the larger the brake surface the less the brake trouble.

Trucks generally are equipped with two kinds of brakes, the internal expanding and the external contracting, and it should be unnecessary to say that they should be tested and kept in the best of condition. Brakes should be such that the car can be stopped at once, but when the brake is released the bands should not drag. Cotter pins in the brake rods should also be inspected to see that none are lost or broken. If brake surfaces be leather, camel hair or some other belting, oil should not be used on them, but if the surfaces be metal against metal, they should be lubricated to prevent "furrowing."

Brakes should not be overworked or strained unnecessarily. Many truck drivers go as fast as they can until they almost reach the desired spot, then "jam" on all brakes and slide the rear tires. This is absolutely uncalled for. A good, careful driver seldom uses his brake, but slows down gradually. On an incline, it is best to set each set of brakes alternately, but in ordinary driving it is almost unnecessary to use the brakes. All slowing or starting can be done by retarding or advancing the throttle.

Tire trouble is another thing that keeps the cost of a motor truck up, but a heavy tire expense is often due to a poor or careless driver. A few given rules can be laid down for this: Don't allow oil to get on the tires or allow the truck to stand in a puddle of oil. Don't start or stop the car with a jerk. Don't round corners at a high rate of speed. Don't unnecessarily turn sharply. Don't turn the steering wheel while the car is at rest.

Digitized by Google

Expense of the rear tires may sometimes be due to the fact that the radius rods are not adjusted an equal amount on each side of the truck, the rear axle is not at right angles to the driving chains and not parallel to the countershaft. Wear on the driving chains will become evident if this be the case. This fault can easily be remedied by tightening or loosening the rods.

More troubles are due to bad driving than to any other cause. It is fool's economy to put a $5-a-week boy on a $5000 truck. Some drivers like to start suddenly and see how big a hole in the road they can make. One large manufacturer says: "The more easily a motor truck is started the better it is for the life of the car." In stopping it is the same. Stop gradually. Don't take a "slide for life." It is dangerous, not only to the driver but to others in the street, for it is certain to cause skidding.

In changing gears, observe the following rules: Throttle down the engine. Disengage the clutch entirely. Shift your gears easily. After the gears are shifted, engage the clutch slowly and advance the throttle until the engine reaches its normal number of revolutions. When you come to a hill, change the higher speed to a lower one as soon as the truck begins to slow down. Don't change speeds after you have stalled the motor. Also, don't change too soon, for that is almost as bad as too late.

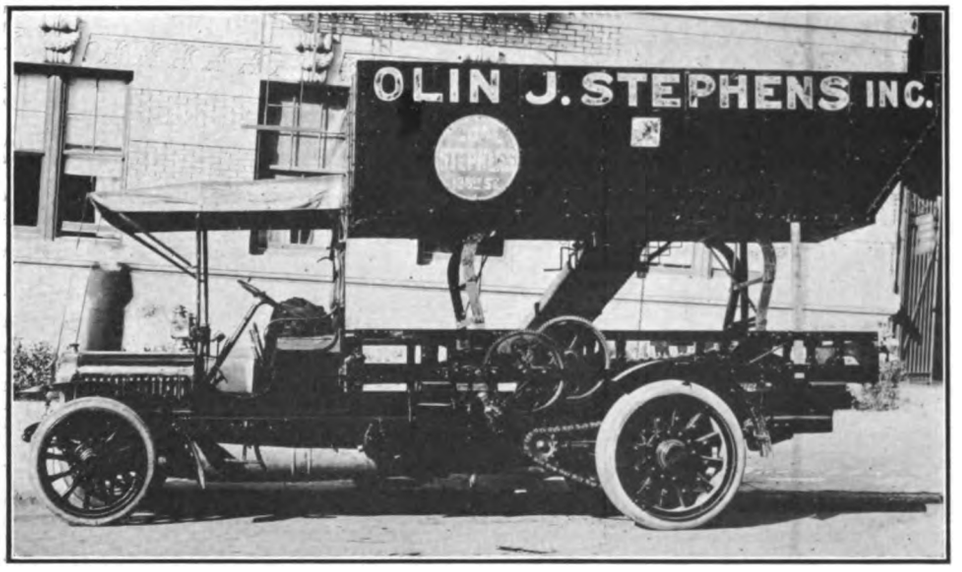
Keep your truck as near its original efficiency as possible, and to do this you will have need to use good common sense, and plenty of good oil at all times.

Very truly yours,
HENRY J. BARBOUR.

Peoria, Ill., Feb. 24.

CONTEMPLATES BUILDING SERVICE STATION.

Editor, MOTOR TRUCK,
Sir:



We will build this summer a suitable sales and service building for automobile business in this vicinity in charge of S. H. Daddow, formerly of Youse & Daddow, Reading, Penn. We are interested in garage building construction, machinery and tools, appliances, supplies and accessories for commercial and pleasure cars. We would be pleased to receive literature on any of these lines. Address all communication to S. H. Daddow, St. Clair, Penn.

Yours truly,
MINERS' SUPPLY COMPANY.

St. Clair, Penn., Feb. 28.

ANNUAL MOTOR TRUCK PARADE.

At a meeting of the Motor Truck Club held at the rooms of the Automobile Club of America, New York City, recently, plans were promulgated for the second annual parade of commercial vehicles which will be held Saturday, April 13. It is expected that at least 500 power wagons will participate, as it is estimated that there is at least 50 per cent. more cars in service than a year ago when the first parade was held. The initial event was very successful, despite the inclemency of the weather, and the display did much to demonstrate the efficiency of the automobile for business purposes. The meeting was well attended, there being present a large number of members representing the leading makes of the country and a general committee was appointed consisting of members of all standing committees, and special duties were assigned to the various branches of the committee organization. It is expected that suitable prizes will be provided in the several classes and special inducements will be offered in the way of prizes for loaded machines.

Saurer Truck Fitted with Coal Dumping Body in Service with Olin J. Stephens, Inc., New York City.

TRUCK ECONOMY IN COAL INDUSTRY.

Among the many industries in which the motor propelled vehicle is replacing the horse drawn equipment is the coal business, and those concerns which have given the motor car a trial are discarding the animal and building up fleets of automobiles. The latter has many and distinct advantages over the slower means of transportation, and the most striking is the cost a ton-mile for delivery.

Among the large coal dealers of New York City is Olin J. Stephens, Inc., whose yards are located on 138th street. This concern placed in service a 6.5-ton Saurer truck, made by the Saurer Motor Truck Company, Plainfield, N. J., and equipped with a Wright dumping body, which is shown in the accompanying illustration. Since this machine has been installed it has averaged from 30 to 50 miles a day, carrying a five-ton load.

The dumping body is fitted to a stock chassis and rests upon substantial sills. It is raised to any desired height by a device which obtains its power from the driving shaft, and the mechanism is simple and controlled easily.

Leading from the body is a chute, through which the fuel passes, and it is claimed that a five-ton load of coal may be discharged in seven minutes. This arrangement permits of the car hauling and discharging 10 loads a day or 50 tons. The machine averages from nine to 10 miles an hour and the gasoline consumption is rated at about one gallon to every five miles.

Compared with the former horse drawn equipment there is large gain in favor of the motor car. A two-horse team hauling about three tons, required from 25 to 30 minutes to unload, and in addition it was impossible to chute the coal the same distance as with the machine.

The operator of the automobile is an employee of the company, who drove a team of horses for 16 years. His employer states that his truck cost them less for maintenance than any other, which was due to the excellent care taken of his outfit. He not only inspected the wagon for needed repairs but gave his animals careful attention and always remained at the barn to see that they were fed, watered and cared for properly.

The company believes that the driver of the horse drawn equipment who is considerate of his outfit, will give the same attention to the automobile, and that after becoming familiar with the machine will develop into a better operator than could otherwise be secured. Obviously, this plan makes for decided economy.

MANUFACTURERS ACT ON OVERLOADING TRUCKS.

ABOUT 40 representatives of prominent commercial motor vehicle manufacturers held a two-day convention in New York, March 4-5, at the headquarters of the National Association of Automobile Manufacturers, Inc., in accordance with a call issued by the commercial vehicle committee of the association. The principal objects of the meeting were to promote better acquaintance among the manufacturers, to discuss trade conditions and to recommend action by the national association looking toward greater uniformity in construction, ratings, warranty and selling methods. Pronounced interest in all questions taken up for discussion was evident and the results of this first general meeting of the trade are most gratifying to the committee.

The following representatives were present: S. D. Waldon, Packard Motor Car Company, presiding; W. E. Metzger, Metzger Motor Car Company; Charles Clifton and H. Kerr Thomas, Pierce-Arrow Motor Car Company; Benjamin Briscoe and Alfred Reeves, United States Motor Company; B. A. Gramm, C. E. Stone and P. K. Dexter, Gramm Motor Truck Company; F. I. Harding, Peerless Motor Car Company; Vincent Link, Universal Motor Truck Company; G. J. Loomis, Speedwell Motor Car Company; Albert L. Pope and W. C. Walker, Pope Manufacturing Company; A. M. Chase, Chase Motor Truck Company; E. O. Sutton, Knox Automobile Company; A. W. Robinson, Locomobile Company of America; A. J. Doty, Lansden Company; Will H. Brown, Mais Motor Truck Company; Walter C. White, White Company; H. F. Flowers and William P. Kennedy, American Locomotive Company; Peter Dumont and George H. Kelly, Baker Motor Vehicle Company; H. S. Diller, Lauth-Juergens Motor Car Company; Morris Grabowsky, Alden Sampson Manufacturing Company; H. S. Stebbins, General Motors Truck Company; C. H. Wallerich, General Industrial & Manufacturing Company; Herbert G. Streat and F. P. Lewis, Knickerbocker Motor Truck Manufacturing Company; J. T. Langhorne, Packard Motor Car Company; E. W. Curtis, Jr., and F. Nelson Carle, General Vehicle Company; David Beecroft; S. V. Norton, B. F. Goodrich Company; C. W. Fletcher, Walter Motor Truck Company; G. A. Hodges, International Motor Company; David S. Ludlum, Autocar Company; H. E. Coffin and R. D. Chapin, Hudson Motor Car Company.

After a short address of welcome by President W. E. Metzger of the N. A. A. M., and a brief talk on trade conditions by Col. Charles Clifton, the meeting was called to order by Mr. Waldon. Following discussions on the different topics, the meeting passed resolutions recommending adoption by the National Association of Automobile Manufacturers of uniform maximum speed ratings with load for motor trucks of different load capacities and uniform weight allowance for the simplest form of body regularly catalogued, as given in the accompanying table:

Table of Maximum Speeds and Loads.

Rating		Miles an	Weights		
Tons	Pounds	Hour	Standard Body (pounds)	Load & Std Body (pounds)	Total Ld-Body-Overload (pounds)
.5	1,000	16	500	1,500	1,700
1	2,000	15	600	2,600	3,000
1.5	3,000	14	700	3,700	4,300
2	4,000	13	800	4,800	5,600
2.5	5,000	12	900	5,900	6,900
3	6,000	11	1000	7,000	8,200
3.5	7,000	10.5	1100	8,100	9,500
4	8,000	10	1200	9,200	10,800
4.5	9,000	9.5	1300	10,300	12,100
5	10,000	9	1400	11,400	13,400
6	12,000	8	1600	13,600	16,000
7	14,000	7	1800	15,800	18,600
8	16,000	6	2000	18,000	21,200
9	18,000	5.5	2200	20,200	23,800
10	20,000	5	2400	22,400	26,400

The question of a standard allowance for occasional overload was given much attention and it was resolved that "in the opinion of the meeting it is inadvisable to encourage the belief that a truck is designed to carry any weight in excess of its rated capacity, or to permit a warranty to apply to any truck which is overloaded." The meeting recommended the preparation of a standard plate for the chassis on which should be stamped the rated capacity of the machine and some such admonition as "Do not overload."

There was considerable discussion regarding the abuse of demonstrations and the advisability of making charges by the day for these, the rate of charge to be based upon the capacity of the trucks. It was the consensus of opinion that such charges should be made, the payments therefor to be refunded upon purchase of the machine. No scale of charges was decided upon.

The desirability of a standard form of warranty was generally agreed upon and after exhaustive discussion of the subject the following form was recommended to the executive committee of the N. A. A. M. for adoption:

STANDARD MOTOR TRUCK WARRANTY.

We warrant the new motor trucks manufactured by us for 90 days after the date of delivery to purchaser, this warranty being limited to the furnishing, in our factory, of such part or parts of the motor truck, as shall, under normal use and service, appear to us to be defective in material or workmanship.

This warranty is limited to the shipment to the purchaser without charge, except for transportation, of the part or parts intended to replace the part or parts which upon their return to us, at our factory, for inspection, we shall have determined were defective, and provided the transportation charges for the part or parts so returned have been prepaid; and provided further that the said failure of said part or parts is shown not to be due to abnormal use, misuse, neglect or accident, occurring after such motor truck shall have been shipped to the purchaser.

We make no warranty whatever in respect to tires, rims, ignition apparatus, lamps, gas tanks, signalling devices, generators, or other trade accessories, inasmuch as the same are usually warranted separately by their respective manufacturers.

The condition of this warranty is such that, if the motor truck to which it applies, is altered or repaired outside our factory, or if it is operated at a speed in excess of its factory-rated speed, or if it is loaded beyond its factory-rated load capacity, then this warranty shall become null and void and our liability under it shall cease.

The number of the motor truck to which this warranty shall apply is .....; and is described as .....

With the object of securing greater uniformity of dimensions in motor truck wheels and bands, it was resolved to recommend that the dimensional tolerances of felloe bands recommended by a technical committee of the Society of Automobile Engineers, after a careful investigation, be adopted by the N. A. A. M. These tolerances are given in a report of the S. A. E. technical committee for February, 1912, as follows:

1 Tolerance in circumference of felloe band shall be as follows.

	Inch	
	Plus	Minus
Before application to wheel	.03125	.03125
After application to wheel	.0625	.03125

Variation from precise measurement shall be uniform over entire width of band.

(This modifies our recommendation in report accepted at the June, 1911, meeting of the society, to meet the requirements of the more extensive manufacture of rigid base tires.)

2 Tolerance in width of felloe band

	Inch	
	Plus	Minus
Up to and including four inches	.03125	.03125
4.0625 to six inches	.046875	.046875
6.0625 to 12 inches	.0625	.0625

3—Variation in trueness of band when placed on surface plate: Band shall touch at all points within .03125 inch up to and including six inches width. Over six inches width within .0625 inch.

4- Variation in thickness of band .006 inch plus or minus.

Digitized by Google

5—Trueness to round. The radial tolerance on the wheel when felloe band is applied shall be .0625 inch plus or minus. This plus or minus tolerance must not occur at diametrically opposite points. There shall be no flat spots or kinks in felloe band on the finished wheel.

Resolutions were also passed recommending that the commercial vehicle committee continue work in the direction of securing data on the width and length of chassis frames back of the seat with a view to possible future standardization of bodies for interchangeability on trucks of the same capacity; also toward securing data as to wheel diameters, height of frame or platform from the ground and corresponding heights of railroad cars and loading platforms.

In connection with discussion of the tire and maintenance questions following a very interesting paper on tires read by S. V. Horton, of the B. F. Goodrich Company, and a talk on maintenance guarantees by W. P. Kennedy, the meeting recommended that the committee obtain and classify information regarding tire mileage in cities having widely different street conditions as concerns topography and character of paving.

Contracts and price reductions on quantity orders were touched upon as matters of interest to the trade, but no action was taken. Mr. Waldon made an interesting explanation of the Packard system of reductions on all orders for two to 50 trucks delivered within one year, and the information was developed that one or two other companies have adopted a similar contract plan.

During Tuesday's session a very informative and interesting talk was made by David Beecroft on delivery delays due to traffic congestion in streets and alleys in Chicago and suggested co-operation of the manufacturers with commercial bodies, architects and other interests with a view to providing receiving departments in office buildings and otherwise effecting changes that would enable trucks to make quick deliveries and get away.

The meeting adjourned to reconvene upon call on June 4 next, and on Nov. 7.

PITTSBURG ADOPTS MOTOR DELIVERY.

As in other leading cities automobiles are revolutionizing the delivery systems of the large department stores in Pittsburg, Penn. Horne's, McCreery's, Boggs & Buhl's, Kaufmann's and Rosenbaum's stores are delivering the greater part of their sales by automobiles, while other concerns are experimenting with the more progressive vehicle.

The largest fleet is maintained by the Joseph Horne Company which has utilized power wagons since 1902. A number of White machines, made by the White Company, Cleveland, O., are in service and these are mostly shoed with pneumatic tires. McCreery & Co. maintains six White cars of 1500 pounds capacity and Rosenbaum's store is equipped with vehicles of the same make. As a result of the use of machines a large number of the stables have been reconstructed into garages and some of these are very complete. Regarding the service a member of one of the leading concerns stated that each vehicle replaced two horse drawn equipments.

SAYS ECONOMY IS CONCEDED.

According to Lin McKie, manager of the commercial vehicle department of the Boston branch of the Velie Motor Vehicle Company, Moline, Ill., it is no longer a question of the economy of the truck over the horse drawn equipment. He bases his statements upon observations made at the shows where the question of economy was rarely asked by prospective purchasers. The average business man is convinced of the fact that the automobile is more economical.

WILL CO-OPERATE WITH DEALERS.

Announcement is made by the United States Tire Company, New York City, that in the future it will discontinue the sale of motor car tires direct to the consumer. Notices have been posted in each of the 26 branches, located in the various cities, stating: "The voluntary retirement from the retail field has been under consideration by the officers of the company for some time. In finally declaring itself out of the retail business the company relinquishes a profitable trade, as all its branches have done a big business in dealing direct with the consumer. However, it was argued that this business should rightfully go to dealers in towns where these branches are located." In making the announcement to the trade the company states that it desires to show in a substantial way it appreciates the decidedly friendly attitude dealers have manifested toward the company's lines.

PROPOSE MOTOR STAGE LINE.

An automobile stage line connecting Augusta and Rockland through Washington, Me., is probable, owing to a spirited contest between the towns of Washington and Jefferson to see which will obtain the new interurban trolley road between Rockland and Augusta. For over 100 years a stage line operated by horses has been maintained between Augusta and Washington and it always has done a large business. Of late the equipment has not been equal to the traffic. When it was rumored that the new trolley line would pass through Jefferson rather than Washington business men in the latter town opened negotiations for automobile service.

ANNUAL PRODUCTION OF RUBBER.

The annual production of rubber of all grades is estimated at 75,000 tons, according to the United States Tire Company, New York City. About 50 per cent. of this total is being used in the manufacture of motor car tires and accessories. About 40,000 tons comes from the valley of the Amazon. Rubber has become the largest individual item in point of value in the import trade of the United States, and a concern like the United States Tire Company utilizes thousands of tons each year.

ACETYLENE STARTING DEVICE.

The Imperial Brass Manufacturing Company, Chicago, maker of brass specialties, has brought out two new specialties which were displayed at recent motor car shows. These consist of a gas regulating valve and accelerator pedal. The former is intended for use in regulating the pressure on acetylene systems, either for lighting or in connection with a self-starting attachment. The accelerator pedal consists of a segment of a circle rising just above the floorboard and may be operated with a forward, horizontal motion, during which movement the foot remains in a natural position.

FLANDERS DELIVERY TYPE POPULAR.

There is a growing tendency among retail merchants to adopt the more progressive form of transport, the automobile, which is not only decidedly efficient but economical. According to the Studebaker Corporation, Detroit, maker of the Flanders "20" light delivery vehicle, 1912 will witness a large increase in the use of these machines. This statement is based upon the results obtained at the recent New York shows where orders were taken for 101 cars during one day. The Flanders is fitted with a body specially designed by experts in the Studebaker wagon plant at South Bend.

RECENT MOTOR VEHICLE PATENTS

Acetylene Generator.

An acetylene generator which is a departure from the usual form is noted in the patent granted Joseph Corroyer, Oakland, Cal. It consists of a removable water dome in which is mounted a turntable valve regulating the dripping of the water to the carbide in the lower vessel. The gas generated is led through a spiral coil attached to the exterior of the device to a bell shaped member which acts as a reservoir and thence to the lights by the usual double openings.

Throttle Mechanism.

A patent has been granted to Charles B. King, Detroit, assignor of one-half to Ora J. Mulford of the same city, for a throttle mechanism which is operated both by lever and pedal, either independently of the other. It consists of a movable, adjustable sleeve attached to the steering post which is slotted. This is fitted with a lug and a pivoted lever, to which the pedal is connected, engages with the sleeve. Another rod is led from the first lever to the throttle of the carburetor.

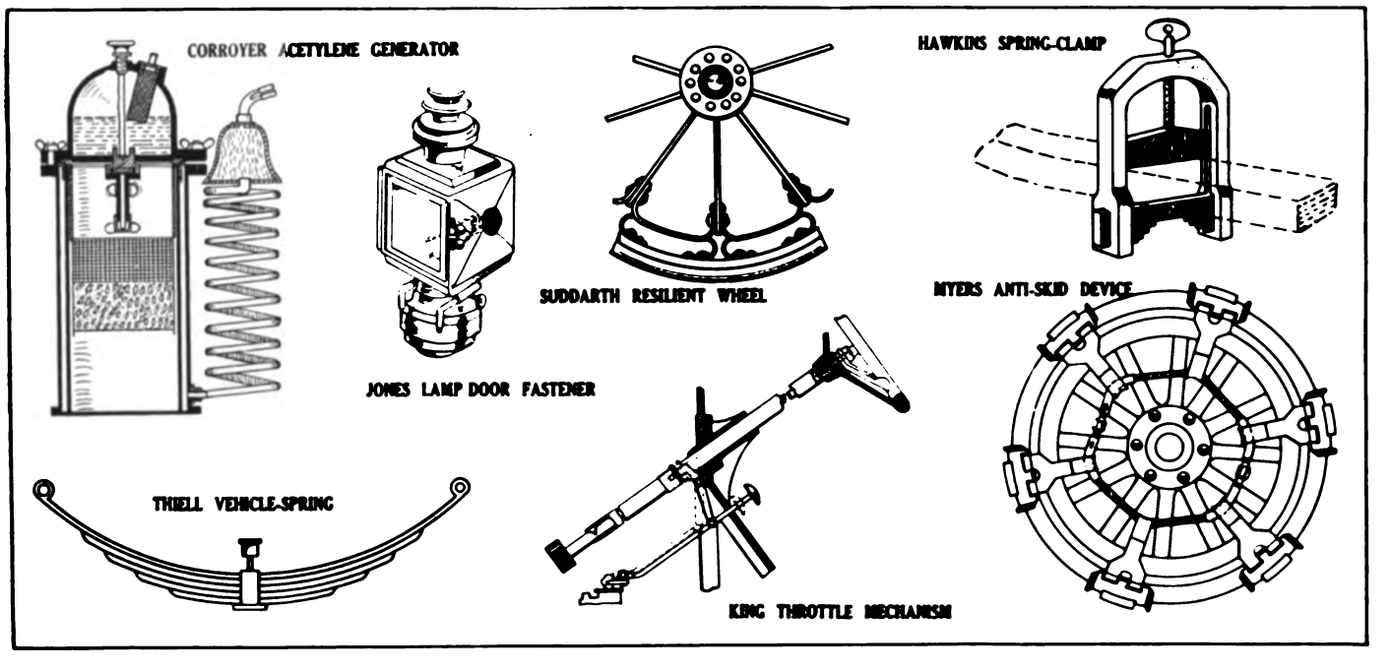
Spring Clamp.

A device adaptable for use as a repair clamp for vehicle springs has been patented by Owen T. Hawkins, Pomona, Cal. It comprises a U shaped frame, and a member moving longitudinally in recesses of the legs of the frame, and a stationary part, the latter having permanent means for preventing longitudinal movement of the member when in normal position.

Anti-Skidding Attachment.

Charles H. Myers, Franklin, Mass., has patented an anti-skidding attachment, consisting of an oblique tread plate, having relatively diverging and transverse flanges upon the outer face, and inwardly extending flanges at the lateral edges, there being slots through the plate, and side plates so arranged as to engage tread members through the slots. There is also a flexible tension device exerting pressure upon the plates in the direction of the centre of the wheel.

Resilient Wheel.



A resilient wheel which utilizes a cushion tire, has been patented by Johnson A. Suddarth, St. Joseph, Mo. One end of the spoke is attached to the hub and the other connected to springs, one side of which is permanently fastened to the rim of the wheel.

Vehicle Spring.

A vehicle spring, the construction of which permits of lubricating the bearing surfaces, has been invented by John S. Thiell, St. Louis, Mo., to whom letters patent have been granted. Each of the series of leaves is fitted with a zigzag groove in its upper face and the members are held together by a bolt having grooves in the opposite sides of the shank portion thereof. The grooves of the latter communicate with those of the leaves and lubricant is fed by means of a cup attached to the bolt.

Lamp Door Fastening.

A lamp door fastening device has been patented by William T. Jones, Detroit, assignor to the Edmund & Jones Manufacturing Company of that city. It comprises a pair of spring arms upon which are mounted spherical members attached to the side of the lamp. A globular member is fastened to the door of the lamp and when the door is closed the globular part is crowded between the spherical members, the latter holding the former securely.

Some Recent Patents of Interest to the Operator, Manufacturer and Dealer, Including Spring Lubricating Device, Anti-Skidding Attachment, Lamp Door Fastener, Throttle Mechanism, Etc.

LIMITING WEIGHT OF TRUCKS.

Manufacturers, owners and prospective purchasers of commercial automobiles cannot fail to be interested in the bill before the Massachusetts Legislature, seeking to limit the weight of vehicles using the highways to six tons. Concerning that portion of the act prohibiting a speed of more than eight miles an hour for cars carrying over four tons, few will be disposed to offer any objection. It would seem, however, that any attempt to restrict the loads carried is a step backward.

It has been pointed out in these columns that certain bridges in some sections of the country districts were not designed to sustain the weights applied to them by the modern methods of transportation. The bill appears to be an effort to transfer the responsibility for damage incurred to these, and incidentally to the truck, from the town to the shoulders of the vehicle owner. Obviously, this is contrary to the established usages. If highways and bridges are incapable of taking care of the increased burden placed upon them it would seem quite the proper thing to reconstruct them.

The importance of the proposed legislation cannot be over-estimated. Massachusetts has set an example for many other states in matters of motoring laws. If this bill is allowed upon the statute books it will mean a decidedly restricted market for cars of more than two or three tons capacity. There can be no good reason for its passage. It does not seem possible that Massachusetts legislators will adopt this radical step, but the situation calls for immediate and effective action.

THE BOSTON SHOW.

Now that the two so-called national motor truck shows have been held, chief interest centres about the first exclusive commercial vehicle show of the Boston dealers. Inasmuch as the pleasure car display in that city always has been considered the largest, most complete and best business exhibition in the country, it is not impossible to forecast the same situation with respect to the industrial transports.

As a matter of history, it may be stated that the first commercial cars purchased and utilized in many of the important cities and towns through New England and the East were purchased at the Boston shows of other years. With an entire week devoted to the exploitation of these vehicles it is not at all unreasonable to assume that this end of the industry will receive a decided awakening in these six states. That the motor truck possesses qualities which fit into the economic problems of these manufacturing communities is well known. All that is needed is an opportunity to bring this home in a direct manner, such as will be afforded by the Boston display.

From the standpoint of the manufacturer or business man who honestly desires to give this problem the best possible consideration, no better opportunity ever has been afforded than that which will present itself in Mechanic's Building, Boston, during the week of March 13-20. One of the largest exhibits of power wagons ever prepared will await his inspection, and with every possibility to study the merits of the respective products side by side. It will be a remarkable assembly of the industry's best representatives, and no business man who desires to keep well informed as to the modern methods of doing business can afford to miss seeing it.

ACCESSIBILITY OF THE POWER PLANT.

Those who have followed closely the new designs brought out during the present show season cannot fail to be impressed with the fact that the manufacturers are devoting a large proportion of their attention to the production of business vehicles which shall present the greatest possible accessibility to working parts. This applies particularly to the power plant, which may be regarded as the chief component of the chassis.

Efficiency of service is the one great aim of the successful truck design. The business man who adopts the mechanically propelled transport to the exclusion of his horse drawn equipment wants to be certain that the newer vehicle will give him at least equally reliable service. Mechanical parts will wear, just as horses will become incapacitated. Present day manufacturers have taken note of this and have arranged to replace the affected part as readily and with the loss of no more time than the replacement of the animal.

Other new features are incorporated into the 1912 designs, but it seems safe to assume that no one subject will attract more attention from the business men than this endeavor to provide for easy, simple and effective replacement and adjustment. In this one respect alone the models offered for the present season are a decided improvement over past design. But accessibility of the power plant is by no means the only progress that may be noted in a careful study of the new vehicles.

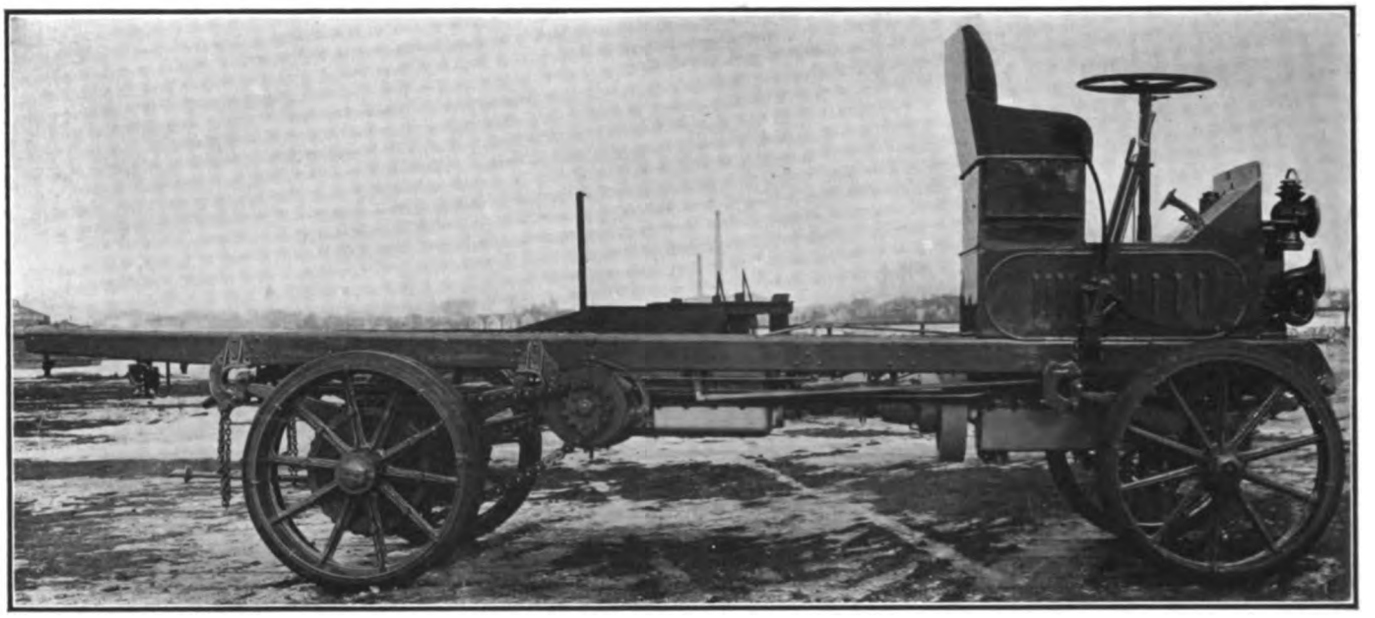
LOCOMOBILE FIVE-TON TRUCK.

Vehicle Designed for Heavy Service and Developed by Long and Careful Experimental Work, Embodying Many Qualities That Commend Themselves to Those Desiring Thoroughly Mechanical and Enduring Construction.

THE advent of the five-ton Locomobile truck at the Madison Square Garden show was the occasion for unusual interest from the fact that it had become generally known that its maker was conducting experiments preliminary to the production of an initial power wagon, although for several years it had built a series of service vehicles that ranged from delivery wagons to ambulances and from police patrols to chemical fire apparatus.



There was decided concern among those in the industry because the Locomobile Company of America, Bridgeport, Conn., is one of the oldest manufacturers of automobile vehicles in this country and it has consistently developed types regarded as typically American. Not since the first machine was marketed in July, 1899, has a car been announced that was not justified in results obtained by the purchasers, and each successive gasoline model has been a development with reference to that which preceded it.

The policy of the company has been to standardize so far as this could be done. Radical changes have never been made. Each production has been distinctly a development in that it has been perfected in detail and carefully refined. The company has an admirably equipped plant and adequate facilities for experimental work and manufacturing, and in A. L. Riker, its chief engineer, has the services of one of the recognized experts of the industry. The Locomobile cars have been looked upon among the standards of the motoring world. They have been known for the care in designing, the quality of material, the character of workmanship and the excellence of finish, the machines harmonizing in appearance and in detail.

In the production of this truck have been combined the results of the long experience of the engineers in designing the differing vehicles built and the data obtained in an exceedingly careful investigation of service wagons and the conditions of their use, this including mechanical practise and commercial methods and usage. The capacity of the truck was decided as being approximately what would best serve the requirements of those engaged in heavy haulage and upon this foundation the design was created and developed. In developing this design every known condition was inquired into and this caused the establishment of factors of safety beyond any question and of construction that would endure under the stresses of hard and continuous industrial service. The purpose was to build a vehicle that would endure such usage at minimum cost and attention.

Truck Design Evidences Progression.

In the design decided progression is evident. This does not mean application of new principles, but the combining and harmonizing of what has been proven and will make for reliability. As an example of sound engineering practise the truck is worthy the attention of every person interested in haulage. Every detail has been worked out thoroughly, and strength, safety, simplicity, accessibility and certainty of operation and control are factors impressed upon those who have examined the machines. Nothing designed for pleasure car construction is used in the truck. It is compactly built and yet has a body platform of large area. The maximum carrying capacity for the wheelbase is insured, the truck may be turned in a radius of 27.5 feet, the view of the driver is perfectly clear, and the operation of the machine has been so simplified that the greatest endurance and reliability has been afforded.

Locomobile Five-Ton Truck Chassis Without Body Equipment, With the Superstructure Covering Motor and Containing Driver's Seat Installed.

One quality believed to be realized to an unusual degree is balance or equalization, this not only with reference to the rotating or reciprocating parts but to the relation of size to ease of handling, of power to strength, to the balance between weight and load, and the distribution of weight when loaded or unloaded. The dimensions of the chassis are as follows: Wheelbase, 140 inches; forward tread, 65 inches; rear tread, 70 inches; length overall, 226.25 inches; width over hub caps, 85.75 inches; platform length, 14 feet; platform width, six feet (or wider); frame

Digitized by Google

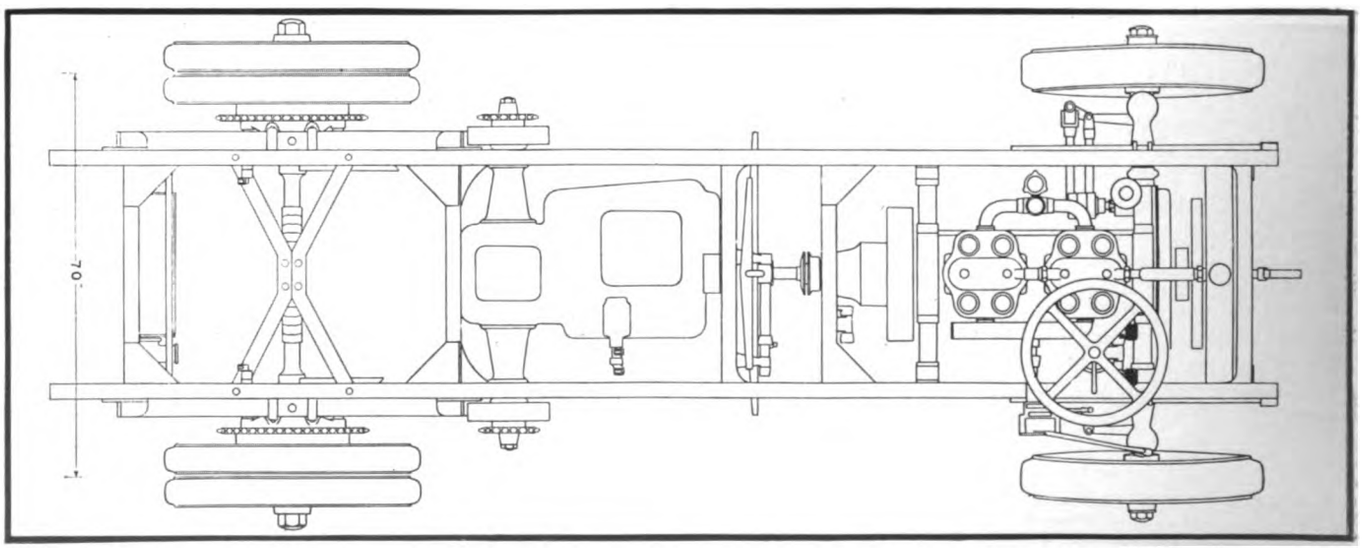
height above ground when loaded, 39.5 inches; platform height above ground when loaded, 46 inches; driver's seat above ground when loaded, 72 inches. When loaded properly the rear wheels sustain about 70 per cent. of the weight, this being a result when a capacity freight is carried. When light the rear wheels carry about 55 per cent. of the truck's weight. This distribution is believed to be the best that can be incorporated in truck design from the viewpoint of securing sufficient tractive effort, minimizing load resistance, equalizing tire wear and insuring ease of control.

Heavy Duty 45 Horsepower Motor.

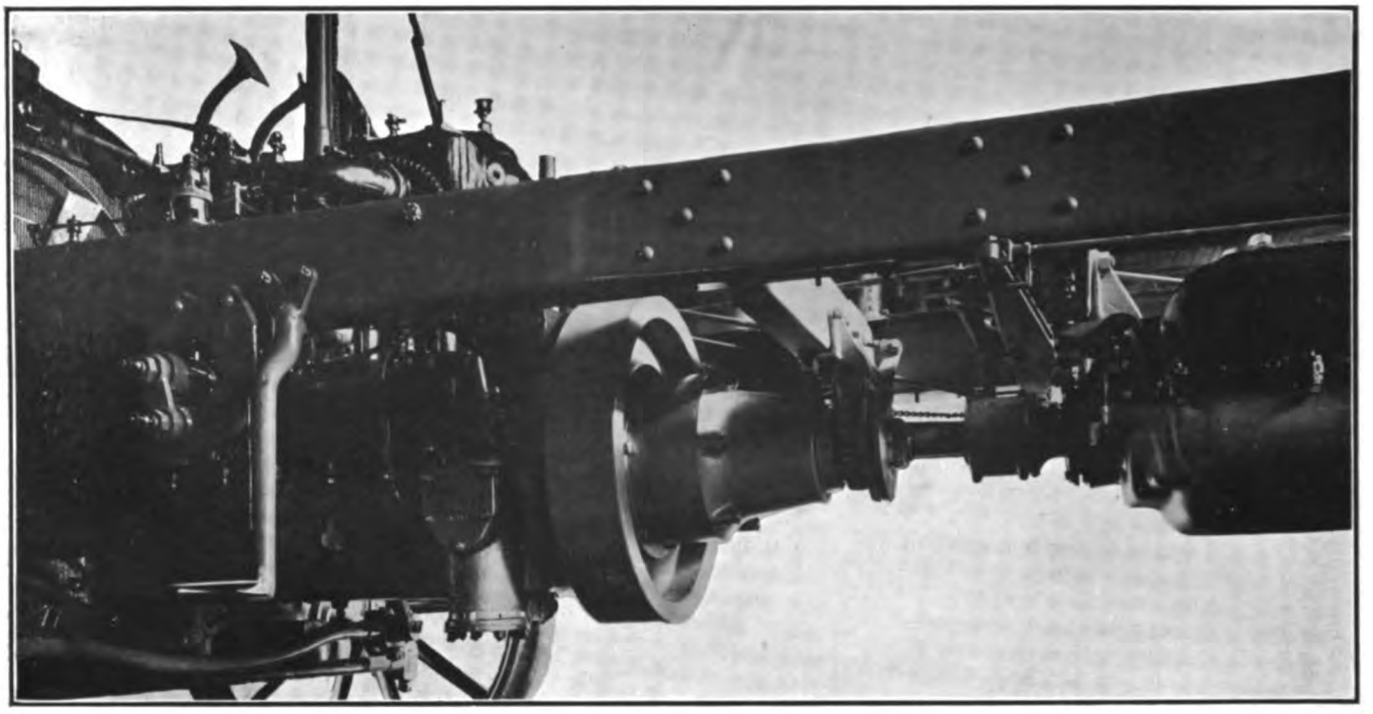
The motor is a heavy duty type with four water-cooled cylinders with bore of five inches and stroke of six inches, developing 45 horsepower at 900 revolutions a minute, which is the maximum speed intended for this engine. While it bears a resemblance to Locomobile automobile motors it differs materially as to proportions and means of installation. It is heavily built throughout, for this means endurance and efficiency.



The T type cylinders are cast in pairs from a fine quality of gray iron and with the water jackets integral. The jacket spaces are liberal to insure efficient cooling and the water outlet manifold is integral with each cylinder unit cap and extends longitudinally along the cap, the caps being respectively front and rear with reference to the form of the manifold. This construction eliminates the possibility of leaky joints as sometimes experienced with the separate manifold. These manifolds are connected between the cylinder units by a large hose section. The cylinder castings are bored, reamed and ground to finish. The pistons are of the same material and similarly turned and ground to size. The pistons are grooved for four rings installed above the wristpin. These rings are .25 inch in width and after annealing to relieve them of all internal stress are carefully ground to an exact fit. The crankcase, as is the practise of the Locomobile company, is a bronze casting divided longitudinally, the upper section carrying the main and camshaft bearings. This construction insures absolute alignment of the main bearings and avoids any possibility of crystallization of the metal from the vibratory stresses from road shocks. The lower section of the crankcase forms a reservoir for the lubricant and when it has been removed the crankshaft, main bearings, camshaft, camshaft bearings and the big ends of the connecting rods may be examined or worked upon.

Five Main Engine Bearings.

The crankshaft is 2.5 inches in diameter and is mounted on five main bearings solidly anchored in the cross webs of the upper section of the crankcase, the journals being secured by lock washer, plain nut, castellated locknut and cotter pin for each bearing. These crankshaft bearings have a projected bearing area of 41.34 square inches which reduces the pressure a square inch of projected bearing to a minimum. This large bearing area makes for a longer life for the bearings and lessened motor troubles.



Generous Water Circulating System.

The cooling system is absolutely positive. The radiator is large and the water jackets and pipe connections so generous that eight gallons of water are required to fill them. The water is circulated slowly by a rotary pump located on the exhaust side of the crankcase at a point midway between the cylinder units and driven by an outside shaft from the timing gear. The water is forced into the cylinders at a point at the base of the exhaust valve chambers, thence it is circulated through the water jackets and from the heads of the cylinder units. The water connections are not perfectly rigid and are not subjected to the stresses of intense heat or vibrations. The radiator is mounted in the chassis frame on large rubber buffers and is behind a heavy cross member for protection, this member being perforated

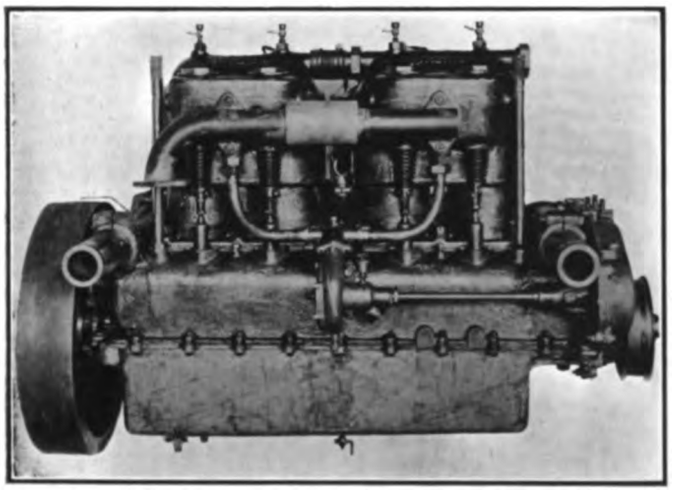
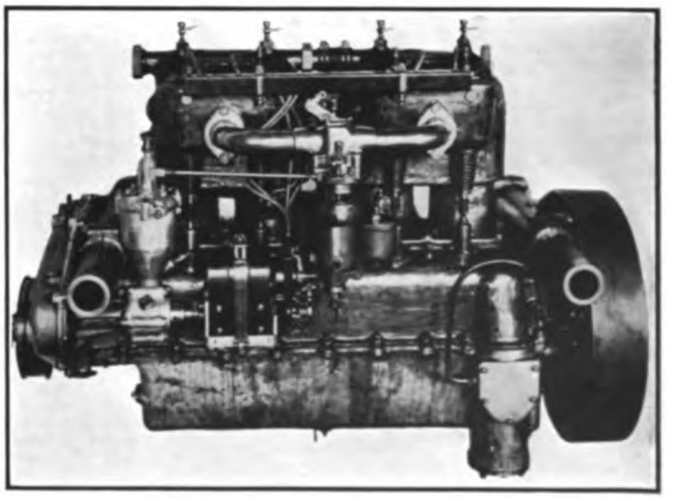
Digitized by Google

Section of Chassis of Locomobile Five-Ton Truck from the Middle of the Transmission Case Forward, Including the Clutch and Power Plant.



with large circular holes to prevent the reduction of the radiating draft through the radiator. Mounted on the front cylinder of the motor is a bracket in which is an eccentric case carrying two ball bearings, in which the shaft carrying the large one-piece aluminum fan is installed. The fan is driven by a 1.75-inch flat belt from a pulley on the crankshaft extension. By loosening a nut the eccentric may be turned and the fan belt adjusted.

Connecting Rods and Their Bushings.



The connecting rods are I section drop forgings and of steel having such strength that the factor of safety is 25. The big end and wristpin bearings are very large and are proportioned to the main bearings. The big end bearings are carried in caps that are held by the same means as are the main bearings. The valve action is conventional, the valves being actuated by right and left camshafts driven by spiral gears from the crankshaft and the valves are large and afford certain inlet of fuel gas and the exhaust of the burned gases. The valve stem guides are cast separately and forced into the cylinder units, this allowing replacement should they become worn. The exhaust manifold is in two parts, one telescoping within the other, this eliminating any stress between the cylinder units from longitudinal expansion, which might change the alignment of the wristpin and crank pin bearings.

Standard Locomobile Design Carburetor.

The carburetor is the standard Locomobile design, being of the float feed type and is fitted with both hot water jacket and a hot air regulator. Only a single jet is used, this insuring ease in starting, but this single jet through its design has the functions of both the single and multiple type jets. The results are the high economy and the satisfaction inherent of the design. No automatic devices have been added. With both hot water jacket and hot air regulator low specific gravity fuels may be used with excellent results, and the hot air regulator has an adjustable opening for the intake of cool air in summer. The carburetor requires no attention from the driver. It is very flexible and affords good mixtures at all speeds. It is controlled by a lever on a quadrant located on the dash.

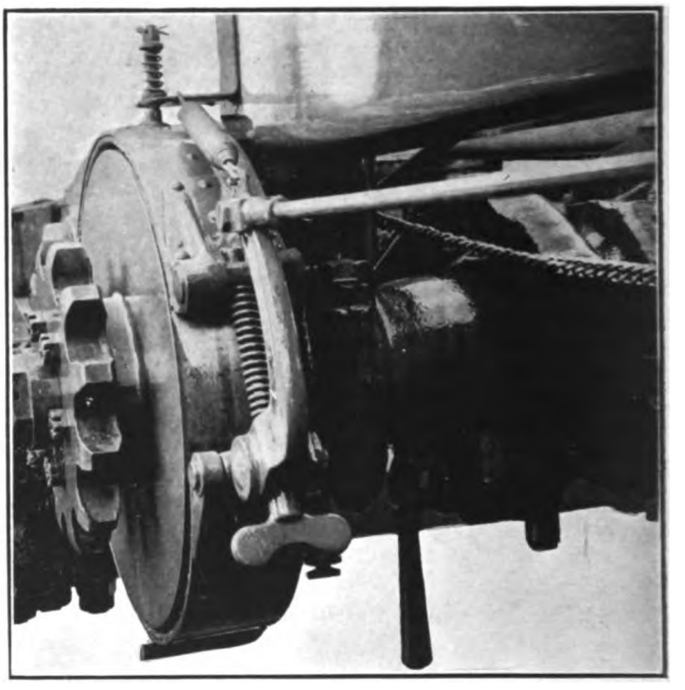
The speed of the motor is limited to 900 revolutions a minute by a specially designed ring governor located at the left side of the motor in front of the magneto. It is of the vertical ring type and is driven off the magneto drive shaft by spiral gearing. The governor ring is mounted on the shaft at a normal inclination to the horizontal plane of 53 degrees and is supported by two cams. It is held normal by a spring, but as the speed of the motor is increased the resistance of the spring tension is overcome and the ring approaches a more nearly horizontal position. After the governor has been adjusted it is sealed that it cannot be changed. The governor prevents speed, which is far more dangerous than overloading, and it assures the owner that the vehicle is not abused. The ring governor was adopted because the ring could be machined to insure perfect balance, as an imperfectly balanced ring would cause vibrations at high speed that would impair the efficiency of the device. The governor is connected by linkage with a butterfly valve in the carburetor which remains wide open at all speeds of the engine until 900 revolutions a minute have been attained. Then the governor operates and the valve is operated, and the supply of fuel controlled.

Unfailing Flow of Lubricant.

The system for lubricating the motor is decidedly efficient, it being self-contained and continuous in operation, combining both splash from the reservoir in the base of the crankcase and force feed from a gear-driven positive pump. This system has the advantage that it cannot be changed by the operator and it will supply a constant and unvarying flow of lubricant. There is no possibility for failure unless there be neglect to replenish the oil, which is a remote possibility.

Motor Rigidly Supported in Frame.

The motor assembly is firmly and rigidly supported at either end in the chassis frame in a manner that is simple,



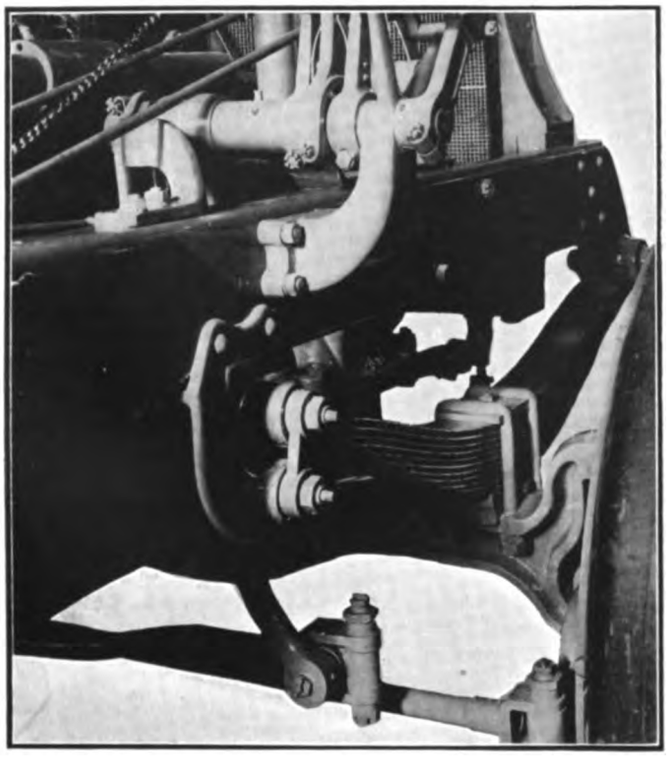
The Governor of the Locomobile Five-Ton Truck Motor and the Dry Plate Clutch of the Driving System.

insures ease in removal and makes certain that upon replacement the motor will be in positive alignment. At either end of the crankcase are heavy lugs through which holes are bored. Two steel tubes, three inches in diameter, are passed through these holes, as may be noted from the illustrations of the motor, and are clamped upon the tubes by clamping bolts. The ends of the tubes are seated in cast steel bearing brackets which are bolted into the chassis frame after the motor has been perfectly aligned, and are retained in these bearing brackets by caps that are bolted firmly. This installation eliminates all strains upon the crankcase and the motor assembly may easily be removed from the chassis should this be necessary.

Dry Disc Clutch Makes Ease in Starting.

The flywheel is exposed and this carries the self-contained dry disc clutch. This construction insures against the plates becoming misaligned. The connection with the transmission gearset is by a driving shaft that has a universal action. This form of clutch has been adopted as being better adapted to withstand the heavy stresses of starting a load from rest than is a cone clutch. The clutch is composed of seven driving discs that engage with six hard-

Right End of the Jackshaft of the Locomobile Five-Ton Truck, the Large Service Brake Drum and Band of the Forward Driving Sprocket.



ened and ground driving bolts attached to the clutch drum bolted to the flywheel. These discs are of .125-inch sheet steel, carefully hardened and perfectly faced by grinding. The seven driven discs, mounted on the clutch disc retainer, are of the same thickness and metal as the driving discs, but are faced at either side with a non-burning heat-resisting material .16 inch thick. The clutch is extremely powerful, is easily released because of the small number of frictional surfaces, may be removed with comparative ease without dismantling other components, and requires practically no attention. The driven members have been made light to minimize "spinning" when the clutch has been released. The clutch is also provided with a brake to better control it.

Heavy Transmission Case and Assembly.

The transmission is cleverly designed and powerful and is constructed to endure hard service. Reversing common practise the upper half of the case is supported by the frame and in this are mounted the clutch pinion, main shaft and countershaft, these being retained by collars. The case is

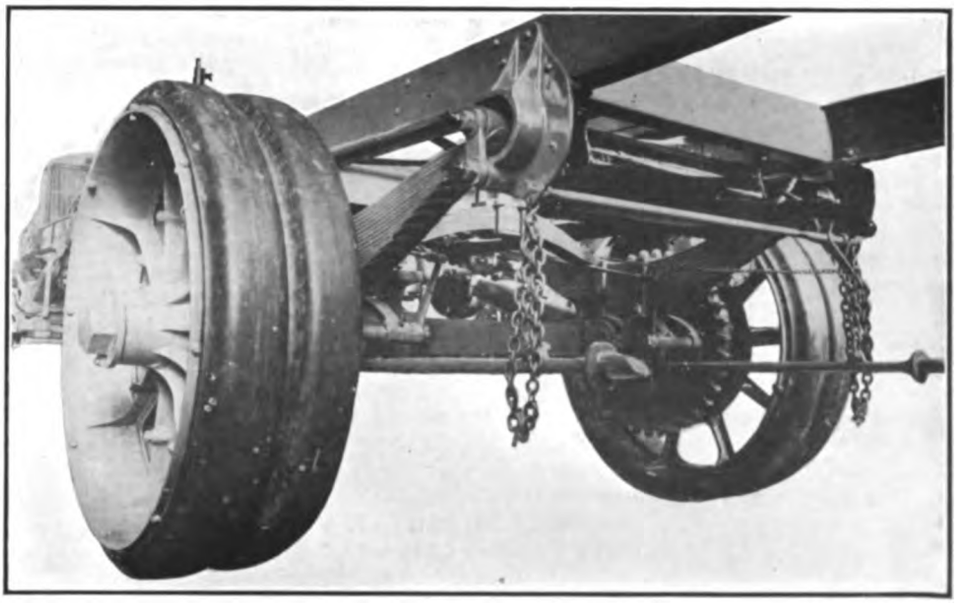
Digitized by Google

of manganese bronze having a tensile strength in excess of 68,000 pounds to the square inch. The bottom section is really an aluminum oil pan which is bolted on. This pan

Forward Suspension of the Locomobile Five-Ton Truck, Illustrating the Wheel Control, Steering, Connecting and Tierods, Front Axle Section and Spring, Spring Clips and Spring Shackles.

may be removed to inspect the transmission, and the clutch pinion, main shaft or countershaft may be removed without dropping the transmission or removing other parts. The case is hinged in front to a channel section cross member and is supported behind by the jackshaft housings, which are bolted to it to form an integral part. These jackshaft housings are held by spherical bearings in cast steel brackets bolted to the chassis side members. This construction prevents any distortion of the chassis straining or in any manner affecting the transmission, as the transmission case will adjust itself in the spherical bearings. All shafts and members of the transmission are mounted in extra large roller bearings save the outer bearings of the jackshaft, which are of the annular ball type. The transmission gearset is selective with four forward speeds and reverse. The transmission gears have faces 1.5 inches wide. They are generated on a gear shaper instead of being milled, so that frictional losses are minimized. The countershaft gears are bolted to the ground faces of flanges, the shaft and flanges being cut from solid metal. The main shaft, instead of being square, has feather keys cut from the solid this giving a greater cross section and increased strength. This design and construction produces a transmission assembly that will endure extremely heavy service with a margin of safety far in excess of all needs.

The jackshafts are, like the main and countershafts, with large cross section and are of a special alloy steel. The squared ends of shafts fit into the differential bevel gears. The outer ends are tapered and on these ends are mounted the service brake drums to which the front drive sprockets are bolted. In the right housing is a compact and strong differential lock so that both wheels may be driven as one in the event of necessity, should but one wheel have good traction. The service brake is actuated by a foot lever. The service brake drums are 13.5 inches in diameter and three inches wide, about which brake bands contract. This brake has a frictional area of 255 square inches and because of the chain reduction has as much efficiency upon the rear wheels as has the internal expanding emergency brake. The emergency brake drums are 18 inches in diameter, 4.5 inches face, with frictional area of 355 square inches. These drums are within the cast steel sprocket drums and are firmly bolted to the rear wheels. Both brakes are equalized and either will hold the truck with a full load on much steeper grades than would ordinarily be traversed.



Drive Chains and Distance Rods.

The drive is by double side chain of two-inch pitch with rollers 1.125 inches in diameter and 1.25 inches wide, with strength of 44,000 pounds, with 12-tooth front and 35-tooth rear sprockets. The sprocket reduction of the truck exhibited is 2.92 to one and the reduction on fourth speed between the motor and rear wheels is 12.8 to one.

The relation of the rear axle to the jackshaft is preserved by heavy distance rods mounted at either side of the chassis frame. These rods are channel section and are bored and bushed at the rear ends to fit the rear axle. The forward ends are fitted with adjustable bronze bushings in which are swivelled yokes, the forks of which fit around and are bolted to bosses on the jackshaft brackets. This construction permits chain adjusting, and serving as universal connections the rod is relieved of undue stresses, while the springs are protected against the driving strain. The rear axle is of alloy steel, 3.5 inches deep and 2.5 inches thick.

Wheels and Springs.

The wheels are mounted on roller bearings of far

Rear View of the Locomobile Five-Ton Chassis, Displaying the Heavy Frame Construction, the Wheels, Springs, Jack Spring, Brake Drum, Rear Sprocket, Spring Shackles, and Sprags.

greater capacity than they will ever be subjected to, being guaranteed to resist at the rear wheels 17,000 pounds to the axle, which will not be reached under the heaviest over-

Digitized by Google

load, while their size minimizes the wear. The spring saddles are fitted around the rear axle and from these the emergency brake shoes are supported, this bringing the braking strains upon the rear axle and relieving the springs of heavy stresses. These rear springs are semi-elliptic, are of 50 inches length and three inches width, with capacity of 6000 pounds each. Fitted above and paralleling the rear axle is a jack spring carried on a chair mounted on diagonal frame members reinforced by heavy gusset plates at top and bottom. This is intended to absorb severe road shocks and to protect the rear springs against overloading. Should there be occasion to carry a load that would necessarily be on a small platform area, not distributed over the entire machine, this construction would protect the rear springs. The front springs are semi-elliptic and 42 inches length and three inches width, with capacity of 2000 pounds. All springs are retained by heavy clips which fit grooves in the spring clip separators, thus preventing movement of the springs in their saddles.

The extreme care taken in the suspension construction is demonstrated in the spring link bolts and shackles. With one shackle the hardened steel link pin, which passes through a bronze spring bushing, is welded to the shackle to form a unit and prevent any movement. The other shackle for the same spring is bolted on. All spring link pins have grease ways and are drilled to distribute grease from the cups, which are cut from the solid metal and are integral with the bolts. The spring brackets are steel castings riveted to the chassis frame by .375-inch rivets. The eyes of these brackets, through which the spring shackle bolts pass, are bushed with phosphor bronze.

Chassis Frame Details.

The chassis frame is in keeping in design and construction with the other features of the truck. It is of channel section pressed steel alloy six inches wide and 2.5 inches deep, and .3125 inch thick. The six channel section cross members are heavily reinforced at top and bottom by large steel gusset plates. Few holes are made in the members and these are drilled and reamed instead of punched. All joints are hot riveted, the .375-inch rivets being carefully headed, inspected and tested. The wheels are of cast steel which are stronger, lighter and are not affected by road shocks. The rear wheels of this truck weigh more than 50 pounds less than similar wooden wheels. It was determined by the engineers after exhaustive experiments that much of the resiliency with wooden wheels was due to the movement of the members in the sockets, which was regarded as being a destructive influence. The wheels used are 40 inches in diameter, it being believed these are more economical of tires, afford larger clearance, and give easier traction. The rear tires are dual, each tread six inches, and the forward tires are single tread, six inches wide. This equipment is believed far in excess of any requirements and ought to minimize the tire expense.

Control Members.

The control of the truck is by a wheel mounted on a vertical steering column, the gear being of the screw and nut type, a triple thread screw of large pitch being employed. In the design large bearing surfaces have been provided to insure against wear, and to compensate any wear by adjusting bushings and nuts. The connecting rod and tie rod constituting the linkage between the steering knuckles are 1.37 inches in diameter, steel tubing, with universal joints. These are behind and have the protection of the front axle from road obstructions. The throttle lever is mounted on the steering column and a foot accelerator is available for use in heavy traffic, so that the driver may have both hands free. There is no hand ignition lever, the Bosch magneto firing the motor 19 degrees before top centre, and when starting the battery circuit fires one degree after top centre. There are separate pedals for the clutch and foot brake, and side hand levers actuate the emergency brake and effect the changes of speed.

The motor assembly is covered by a superstructure that also carries the driver's seat and which may be quickly removed should it be necessary to grind the valves, for instance, without removing any of the control apparatus. The driver's seat is hinged to be turned or folded backward on the truck deck, and the aluminum floor boards and the sides of the superstructure may be removed to inspect the motor. The gasoline tank, of 25 gallons capacity, is beneath the driver's seat and is connected with the carburetor by a flexible metallic tube.

The Locomobile truck equipment includes standard accessories and tools, such as Prest-O-Lite tank, odometer, lamps, jack, repair kit, etc.

NEW REMY LOW SPEED MAGNETO.

A new type of magneto, specially designed for trucks or tractors employing low speed heavy duty motors, is announced by the Remy Electric Company, Anderson, Ind., maker of ignition specialties. The new product is listed as type R F and has three sets of permanent magnets, large laminated inductors, ample stationary winding and a heavy oak coil.

Before placing the device upon the market it was subjected to most extensive tests for electrical and mechanical efficiency and it survived these successfuly. In addition it was subjected to endurance tests in the Remy plant and at laboratories of various motor car manufacturers. It was particularly subjected to throttling down trials.

The new magneto offers all of the details of construction found in the new Remy multi-cylinder high speed magnetos, and is designed to withstand severe service. All wearing parts are of the best chrome vanadium nickel steel, carefully and scientifically measured and tested for hardness and wearing qualities by instruments such as the scleroscope and other devices.

The magnets are of the finest tungsten steel, heat treated and hardened by a special process in the Remy plant. The inductor shaft is of high grade steel and ground accurately to size. The cams are of chrome vanadium nickel steel, ground to size, inside and out, fitting the magneto shaft perfectly. They are hardened in a special furnace equipped with a pyrometer insuring accuracy in temperatures.

The cam house of the new magneto is smaller and more refined than heretofore and incorporates effective improvements, retaining at the same time all of the Remy standard features of outside adjustability and simplicity. The contact screw is held by a lock spring and to make an adjustment the former is pulled up and the screw turned a few notches. This makes it possible to set the device accurately without tools of any kind. Inside of the cam house is an oiling wick which sets against the cam, ensuring proper lubrication at all times. The cam house, which is removable, is held in position by a stiff spring mounted on a stud which projects from the base of the magneto. The distributing parts are constructed of a new material known as bakelite. Special magneto cone type ball bearings are employed to eliminate noise.

SAMPSON DEVICE FOR WINTER DRIVING.

Recognizing that winter gives delivery systems their severest tests, three important features have been incorporated in Sampson trucks, made by the Alden Sampson Manufacturing Company, Detroit, a constituent of the United States Motor Company, New York City. These consist of detachable hubs, by means of which a change to winter equipment may be made quickly; a differential locking device for securing traction with both rear wheels, and an enclosed chain drive.

ANTI-FRICTION BEARINGS FOR WORM GEARING.

Victor W. Page, M. E., Again Makes Reply to Criticisms Offered Concerning His Original Discussion of This Interesting Subject.

CONSIDERING the subject of anti-friction bearings for worm gear mounting in the December issue of MOTOR TRUCK, Victor W. Page of the New Departure Manufacturing Company, Bristol, Conn., arrived at conclusions which were questioned by H. Kerr Thomas of the engineering force of the Pierce-Arrow Motor Car Company, Buffalo, N. Y. The discussion was continued in the January and February numbers, in the latter of which John Younger, also of the Pierce-Arrow engineering force, united with Mr. Thomas in questioning Mr. Page's position. Again Mr. Page makes reply and MOTOR TRUCK believes the discussion is of sufficient interest to its readers to reproduce the entire letter with accompanying drawings.

Editor, MOTOR TRUCK, Pawtucket, R. I.

Sir:

I am in due receipt of your favor of the 31st ultimo and again desire to express my thanks for your courtesy in permitting me to answer the letters of criticism, copies of which you enclose. I have read these over carefully, and while I can now see that I made an error of some magnitude, still I am not convinced that my critics are entirely correct in all their statements and I am sure that some of my remarks have been misunderstood.

As the article in question dealt with a main idea of adaptability of double purpose bearings to resist both thrusts and radial loads and not with points involving worm gearing design, I feel that the criticisms of both Messrs. Thomas and Younger regarding my practical experience with worm gearing were uncalled for. In my original article direct reference was made to the loss of efficiency when plain collar bearings were used to resist thrusts, in order to make the advantages of anti-friction forms clearer. Arguments advanced regarding difficulty in securing adequate lubrication and coefficients of friction applied specifically to plain collar forms of thrust bearings and not to worm gears. As Mr. Thomas agrees with me that these are not suitable, and that he would never advocate their use, I can see no reason why further discussion of this point should be made. It is admitted that one of the objections to their use is difficulty in oiling and power loss if subjected to more than moderate pressure.

In answering the criticisms anent my reply to Mr. Thomas it is necessary to remind your correspondents of one important fact, and that is, that I did not attempt to pose as an authority on worm gear design, and distinctly stated so, and did not attempt to attack worm gearing, as Mr. Younger and his confrere evidently believe if this can be judged by their justifiable defense of worm gearing. Surely the paragraph which follows, taken from the original discussion, would tend to dispel any thought that I wished to pose as an authority "It is not the purpose of the writer to consider design or analyze closely the methods of obtaining accurate tooth form, but rather to discuss the problem of mounting, which is recognized as one of the important conditions making for successful installation." This could never be misconstrued and make a discussion which pertained only to the adaptability of the double purpose bearing for resisting both thrust and radial loads an exposition on the merits, lubrication or design of worm driving gearing

If in his reply to Mr. Thomas' first letter, the writer brought forth facts to prove that plain collar type bearings were not suitable to take worm thrusts, it was because it was this point that was considered in the original discussion, and not difficulty in worm gear lubrication. No point was made that worm gears could not be lubricated satisfactorily. Surely the results obtained in actual practise would prevent any one even remotely familiar with automobile construction (and even without the advantages of the correspondence course so earnestly recommended by Mr. Younger), from making a statement so widely opposed to actual facts. The point was made, however, that there would be difficulty in securing adequate worm lubrication if the thrust were 30,000 pounds while the gearing was in operation, the truth of which will not be questioned. As Mr. Thomas has made plain that this pressure only exists at a time that one would not need any lubricant between the teeth because the gears were not turning, it would seem that the fact that no oil would be present between the teeth did not matter much, one way or the other. Let it be remembered, however, that Mr. Thomas' estimate of the maximum load existing, or 30,000 pounds, was figured when the gearing was at rest and was compared to the loads given by the writer when the gearing was in motion. This fact alone would account for considerable discrepancy between figures, even assuming that both of us were correct in our original statements. As Mr. Thomas did not fully qualify this rating, or state clearly the conditions obtaining at the same time the load existed, the writer assumed that comparison was made under the same conditions that existed when he made his deductions; that is, with the gearing in operation.

There was an error of some magnitude in following out the formulae in the writer's original article, and both Mr. Younger and Mr. Thomas are right in stating that my first estimate of tooth pressures was too low. I have carefully gone over my original figures and corrected the error. No excuse except gross carelessness on my part in going over the matter too hastily can be given for the original error. Needless to say, had the problem been one of actually selecting bearings for a typical installation and making recommendations, it would have been settled in a much different manner. A graphical layout would have been made and checked over by competent engineers before any sizes were recommended. If Mr. Thomas will overlook my first pique, at what on more mature reflection I see was well meant criticism on his part, and attribute it to zeal in defending the usefulness of a bearing that has so thoroughly proven its worth, rather than ignorance (as Mr. Younger perhaps a little too hastily assumed) I wish to express my thanks for his calling my attention to errors of some magnitude.

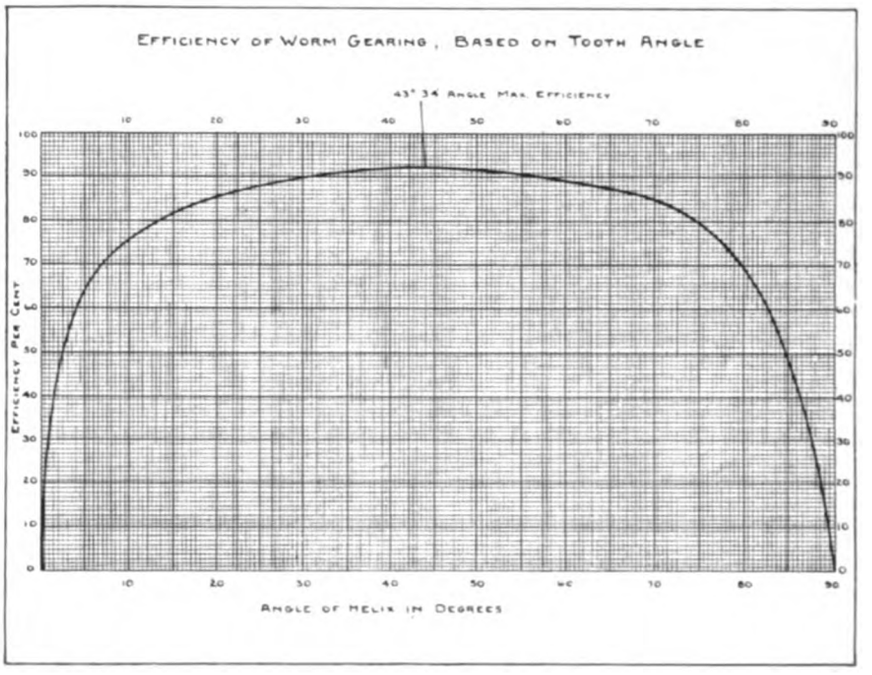

Chart Showing Efficiency of Worm Gearing, Gives a Value of 88 + Per Cent. for Tooth Angle of 26 Degrees 45 Minutes.

I wish to assure both of these gentlemen that I do not question their experience with worm gearing, and I questioned their loads merely because my experience with anti-friction bearings showed it would be difficult to use these if the loads were exceptionally high and the speed of rotation did not diminish in proper ratio to alter conditions.

Consider the conditions stated by Mr. Thomas where 30,000 pounds is given as the pressure between gear teeth caused by "sudden application of engine power," which would immediately cause the engine to stop because the resistance is so much greater than the force applied to the worm gear, or condition, "B Locking of brakes if fitted to transmission shaft." In either of these cases, the worm rotation is very slow. In one, that of braking, it may be stopped altogether. If this pressure obtains between the teeth under these conditions, the effect on the thrust bearing is materially different because it also is turning very slowly. This is recognized by Mr. Thomas in his letter of Jan 19 wherein he says, "But fortunately this force does not exist (except)

Digitized by Google

when running at very low speed." The slower a ball bearing of given size turns, the greater its load carrying capacity. For instance, a bearing of the cup and cone type having 35-degree load line which will carry but 55 pounds thrust at 2000 revolutions a minute will sustain 180 pounds at 200 revolutions. The capacity of a bearing of the cup and cone type under thrust load is not as high as that of the usual ball thrust washer type. With the line of contact practically at a horizontal plane or parallel to the shaft, the resistance of the stationary thrust bearing will be proportionate to the elastic limit of the balls times the number of balls used in the bearing. With a cup and cone type having an angular contact, the thrust resisting power will be less with increasing angularity of load line from the horizontal. If the bearing be rotated, the load capacity decreases when the number of revolutions increase.

Assume that a pressure of 30,000 pounds exists between the teeth when the wheels skid from a well applied braking effort. At this time the wheels are stationary or they would not skid and the worm gear and worm are also at rest. If the wheels are moving slowly, the worm shaft is moving correspondingly slow. Therefore, when the conditions are such that the worm teeth are subject to a thrust of 30,000 pounds, they are also favorable to the bearing, whose capacity for resistance is augmented many times because of the exceedingly slow speed of worm rotation.

Mr. Thomas has considered the loaded rear end weight of the truck to be 16,000 pounds. Perhaps this is right for the truck Mr. Thomas is interested in, but reasoning from current practise, it does not seem reasonable to impose such a proportion of the load on the rear wheels, as this appears to be.

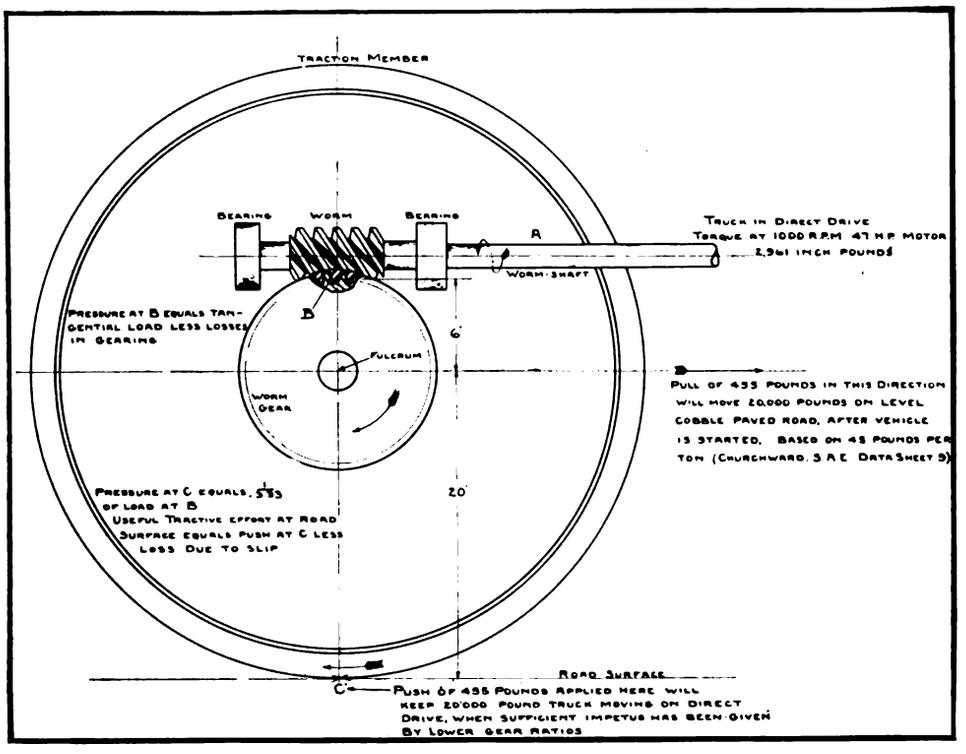

Fig. 1—Outlining Conditions Assumed in Determining Thrust Loads on Worm Teeth When Truck Is on Direct Drive.

The weight for a five-ton truck chassis and body, obtained by taking an average of the published weights of eight American trucks of that capacity show that the usual weight is about 8000 pounds. Say that it will weigh as much as its load capacity, or 10,000 pounds. If this be the case, the 16,000 pounds cited by Mr. Thomas is four-fifths, or 80 per cent. of the vehicle load placed on the rear axle. Engineers usually try to distribute the load more evenly. In fact, 70 per cent. of the net load over the rear axle is usually considered a fair proposition. The writer does not question Mr. Thomas' figures as relates to the weight of his truck, but if correct, it must weigh more than other trucks of its capacity. My recollections of the chassis as displayed at the show is one of unusually substantial proportions, which is a fault only when carried to excess. If the truck weight is not high, then the proportion of load carried by the rear end is high if compared to current practise.

In contending that the loads would be as given, the writer figured from the power plant and back through the gearset, and the tooth pressure existing at the various speeds was taken in order to find the greatest pressure which would be present while the gearing was in motion rather than at rest. Cognizance was taken of the power loss due to gears and bearings of gearset, because the net power applied at the worm and not the primary engine power must be considered in basing the size of the bearings to be used to resist both thrust and radial loads obtaining incidental to worm operation. Then, too, while the writer based his figures on the torque of the motor, both Mr. Thomas and Mr. Younger have worked from the other end of the vehicle. The writer is still under the impression that the figures stated by Mr. Younger are too high. Surely, they do not check up with the tooth loads imposed by the torque of the motor which must be considered a factor of some moment, inasmuch as it is the pressure resulting from it between worm and gear teeth that produces motion of the vehicle.

In selecting ball bearings to resist the loads given, we will not attempt to consider the tooth load when reverse gears are engaged; in fact, common practise in selecting bearings according to catalogue ratings is to take the load existing on intermediate speed as that for which the bearing should be selected. In his letter, Mr. Younger says that the thrust on second speed is 6400 pounds and intimates that it will be necessary to use a double purpose bearing 12 or 15 inches in diameter to take it. We will not consider this too seriously until we see what size ball thrust bearing of the conventional type will be needed to sustain this thrust at a worm rotation of 500 revolutions a minute. Surely, this thrust must be resisted by some means, and we all seem agreed that ball bearings are suitable for that purpose, if selected with reference to the loads which obtain. Refer to bulletin No. 25 issued by Standard Roller Bearing Company, Philadelphia, Penn. This gives capacities of various bearings of the regular ball thrust washer types. No bearing is listed to take this load at 500 revolutions a minute, but at 200 revolutions a minute we find that either bearings No. 1407, 2407 or 3407 can be used to support loads of 6480 pounds, which is about the load said to be present by Mr. Younger. In this connection we must note also that the speed of rotation is much lower; in fact, less than half that of the worm when it is on intermediate or second speed. This bearing has a bore of 2.5 inches, an overall diameter of 6.875 inches and uses nine 1.375-inch balls. Now, this is a fair sized bearing, and yet according to the tables prepared presumably for the guidance of engineers, this bearing will not support this load safely at speeds in excess of 200 revolutions a minute. At speeds of 500 revolutions we find that bearings 1309, 2309 and 3309 will sustain a load of 3510 pounds, or a little more than half the load determined to exist by Mr. Younger. This is also a respectable size bearing, as the bore is 3.5 inches, the diameter 7.125 inches and 11 1.25-inch balls are used.

Seeking still further we fail to find a bearing listed capable of taking the load said to exist by Mr. Younger at the speed or rotation at which the thrust exists. At the other hand, take the condition stated by Mr. Thomas, or 30,000 pounds on the teeth of a stationary worm. Here the same condition obtains as in a crane hook thrust bearing, where movement is very slow; in fact, it is merely an oscillating movement rather than a continuous rotary one. A S. R. B. bearing No. 1407 will resist a thrust of 33,000 pounds safely under the conditions stated. While this is not an exceptionally large bearing, it is a fair sized one as has been shown previously and could be used reasonably if its thrust-resisting capacity was adequate to sustain the load said to be present by Mr. Younger at 500 revolutions a minute, but it is not. Here, then, we have the peculiar condition of a bearing capable of taking the maximum thrust under one condition, being entirely unsuited to resist a stress of about one-fifth its value under other conditions of speed.

It was this fact that led the writer to question the load ratings given by Mr. Younger. Surely, these are too high or else bearings used when these pressure obtain are very much overloaded unless they are of very large size. By the use of large balls, very severe loads can be resisted, but when these are employed, it makes an increased bore and diameter necessary to take the same number, and if the bearing size is kept down, the number of balls and carrying capacity are reduced proportionately. There is a fixed relation between the two which makes it imperative to use larger bearings as the loads augment, a self evident truth that seemingly is not considered fully by Mr. Younger when stating the loads existing at the worm teeth. The effect of speed of rotation must be considered in figuring bearing capacity. It would be very difficult to select a bearing that would not be impractically large if the thrust loads were as high as stated. I agree with Mr. Younger that it would take a bearing at least 12 inches in diameter to resist a load of 6400 pounds at 500 revolutions a minute. A conventional ball thrust washer of that diameter would be needed if one were to judge from the capacities listed in bulletins considered. This will only resist loads in one

Digitized by Google

direction, which means that two of these, as well as two radial bearings, would be needed to support the worm shaft.

To show that double purpose bearings can be used for worm gear mounting, let us consider the load imposed by the engine, compare it to the tractive effort needed to maintain motion of the vehicle and arrive at the load existing between the teeth of worm gearing by considering the power applied, rather than the resistance or push at the contact point of road and wheel, said to exist by Mr. Younger. Obviously, this must be less than the useful energy given to the gearing or the vehicle will not move. An engine of given power can give no more than a certain torque, this in turn can only produce a definite pressure between gear teeth. This pressure must be greater than resistance to vehicle movement if the engine have sufficient power to propel the vehicle. Neither Mr. Younger nor Mr. Thomas questions the fact that 40 horsepower should be adequate to drive a five-ton truck under reasonable conditions. The writer will endeavor to show the line of reasoning he believes correct when determining bearing sizes to resist loads caused by pressures existing between gear teeth which must be taken when this gearing is in motion, and not at rest.

Let us endeavor to arrive at the reason for the variation between the loads given by the writer in this letter and those stated by Mr. Younger in his. Evidently, Mr. Younger has assumed that practically the same power is utilized at all vehicle speeds, which is not true. The road resistance is much less when the second speed gearing can be used than when the low gears must be employed. The gearing is used so the engine can be run up to speed and maximum power obtained at those times that the resistance is too high to permit of the truck moving ahead on the direct drive. Obviously, it is not just to base the tooth pressures on the amount of horsepower of the motor, by multiplying this by the speed of the vehicle and disregard the other conditions. I recognize that my faulty reasoning in original articles made the loads too low, which I would have discovered soon had I checked up the matter carefully. In his haste to defend worm gearing, could not Mr. Younger make an error and figure his loads too high?

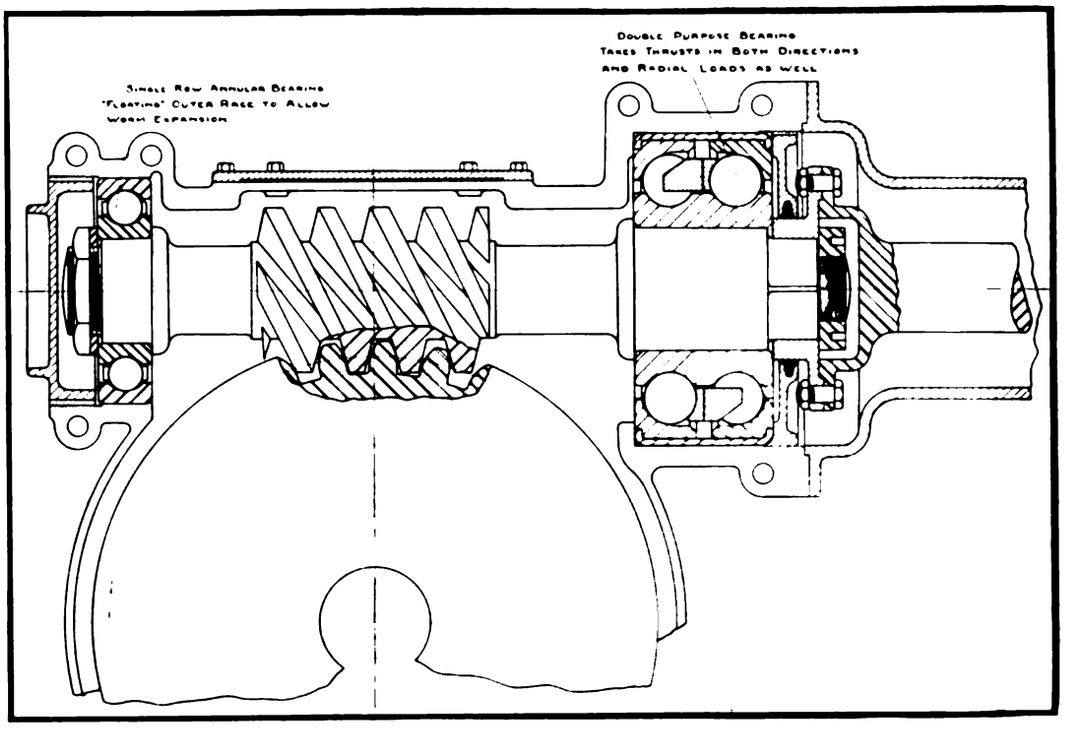

Fig. 2—Suggestion for Mounting Double Purpose Bearing to Resist Thrust in Two Directions and Carry Radial Load as Well—Note Simplicity of Housing and Unit Construction of Thrust Member.

In my first article I considered the matter solely from the point of view of the bearing enthusiast and when the loads worked out so favorably to ball bearings, I did not give the matter the thought it deserved. Mr. Younger considers the matter of load solely from the point of view of one interested in worm gears. In one case I was satisfied to find the tooth pressures and resulting thrust and radial loads low, because I thought only of bearings. At the other hand, Mr. Younger tries to make the tooth pressures as high as possible with a given horsepower to show the value of worm gearing. This leads both of us to make statements that are open to question and an unprejudiced engineer who followed the controversy might be forgiven for suggesting that a review of the elements of mechanics would benefit us both. In making an effort to end the controversy with this reply I will try to go more fully into the solution of the problem than either I or my critics have previously.

In his figures, Mr. Younger takes the horsepower delivered the worm when the change speed gearing is in operation at too high a value, because he quotes an ideal efficiency. While the motor delivers 47 horsepower at 1000 revolutions a minute, considerably less than this will be imparted to the worm gear teeth by the worm. Two main sets of losses must be taken fully into account. First, those existing in gearset when change speed gearing is in operation. Second, that existing at the driving gears at all times they are in motion. On the direct drive, one need only consider the latter, while the former must be considered first, then the other loss deducted when on the other speed ratios.

The writer agrees with his critics that his first figures were wrong, but cannot see how transmission losses can be disregarded. When on the low and intermediate speeds there are two pairs of gears and bearings working, besides the driving gearing. Considering a loss of 12 per cent. for the change speed gears the 47 horsepower delivered to the front end of the gearset becomes but 41.3 horsepower on the drive shaft, which in turn becomes 15 per cent. less (assuming a worm gear efficiency based on teeth 26 degrees 45 minutes angle), or about 35 horsepower at the worm gear teeth. Therefore, in figuring pressure existing between worm and worm gear teeth the materially reduced power effort, which is directly affected by the entering torque, must be taken into account.

The loss due to driving through ordinary worm gearing is greater than five per cent. It will more often reach a value of 15 per cent. loss as shown both by chart presented herewith and by formulae given in original article. On the reverse drive we would not be delivering 35 horsepower to our worm gear but the energy applied would be about 34 horsepower because of the 15 per cent. loss in the gearset with reverse gears in mesh. The actual pressure existing at worm gear pitch circle must be computed on this basis because of driving gearing losses. This might be reduced further by driving shaft angle and universal joint loss. We will disregard this, however, in the case in point, and assume that the truck has a straight line drive with no possibilities for power loss except through the gearing and it must be apparent that the gearing considered would have a materially lower efficiency than the form which Mr. Younger has in mind.

In basing his estimates of power or push exerted at rear wheels he has considered that his worm gearing is working under such conditions that it has an efficiency of 95 per cent. He also disregards my stated efficiency of 85 per cent. and substitutes in its stead his own value. I based the value I gave on the chart presented herewith, the exact derivation of which I am not familiar with, but which I used because it appeared reasonable and checked up the formulae. I would like to call Mr. Younger's attention to the fact that in the case stated the angle of thread was 26 degrees 45 minutes. Using the chart I found that the efficiency given for this thread angle was about 88 per cent., checking my previous calculation. Taking into account that this related to perfectly machined and fitted worm gearing; in fact, a tool room job rather than a regular commercial proposition, I deducted another three per cent. to take into consideration any defects which would make the actual efficiency less than that given in the chart. In view of this explanation, I feel that I was taking a safe value for the efficiency and ask why Mr. Younger should object to my retaining it in my calculations involving this specific case and not the nearly perfect worm gearing he has designed; and probably has in mind when he gives the higher efficiency? In fact, the chart shows that with a tooth angle of 43 degrees 34 minutes we reach the maximum value, which is given at but 92 per cent., this being less than that used by Mr. Younger.

Considering tractive effort needed for commercial vehicles with solid tires as given by Churchward on S. A. E. data sheet No. 9, we find a value ranging from 18 to 26 pounds a ton given for level asphalt. Multiplying the maximum value of 26 pounds by 1.75 which is the ratio the tractive effort required on cobble stone paving bears to that needed on level asphalt, we arrive at the conclusion that a drawbar pull of 45.5 pounds will keep a ton load moving if this be supported

Digitized by Google

by rotating members. This is a high value and it will probably take less than this. This would mean that a pull or push of 455 pounds would move 10 tons, or the loaded weight of the average five-ton truck after it had once been started. Operated under these conditions, the direct drive could be used. The point to determine now is the pressure applied to the worm gear teeth by the engine and see if it will supply the necessary tractive effort to the tires of the driving wheels. Take the engine rating first considered by the writer, that of 47 horsepower at the speed of 1000 revolutions a minute. Turning moment or torque delivered the worm shaft may be determined by the following simple formula (taking the constant 63 as a value based on 1000 rpm):

$$Pp = 63 \times H.P.$$

Substituting known values we have a torque at the centre of the worm shaft of 2961 inch-pounds. Dividing this by the radius of the worm or 1.5 inches we get a load at the worm teeth of 1974 pounds. This, minus loss, is applied to the short arm of a simple lever of the first class (with the fulcrum between the load and power) that has a ratio of 3.33 to one. The pressure applied at the short end will be reduced to less than a third at the long end. Taking a gear efficiency of 85 per cent. we will have an actual pressure of 1698 pounds at the short arm of the lever. Dividing this by the ratio of leverage or 3.33 to one we find that the actual push at the wheel peripheries will be about 510 pounds.

In this connection the writer would say that if he were considering a truck design, he would provide a lower ratio of drive than eight to one, especially if 40-inch wheels were used, because the vehicle speed under these conditions would

Using the same formulae given in the original article, but supplying correct values in this instance, I arrive at very much the same conclusion reached by figuring tooth loads from entering torque of motor at the worm. This line of reasoning follows, the condition assumed being 40 horsepower delivered to worm gear which is turning at 125 revolutions a minute with truck on direct drive:

First find turning moment on worm gear shaft by the following formula:

$$P = \frac{63{,}025 \times H.P.}{N} = \frac{63{,}025 \times 40}{125} = 20{,}168 \text{ inch-pounds.}$$

To find moment on worm shaft we can use the following formula:

$$Tw = \frac{T \times I}{E \times N}$$

Where—

T = Twisting moment at worm gear shaft.
I = Index of threads, 1 for single, 2 for double, etc.,
E = Efficiency for gearing,
N = Number of teeth in worm gear,

Substituting known values we have:

$$\frac{20{,}168 \times 4}{.85 \times 32} = 2965 \text{ inch-pounds.}$$

To find pressure at pitch line of worm we use the expression:

$$P = \frac{Tw}{R} \text{ or } P = \frac{2965}{1.5} = 1976.6 \text{ pounds.}$$

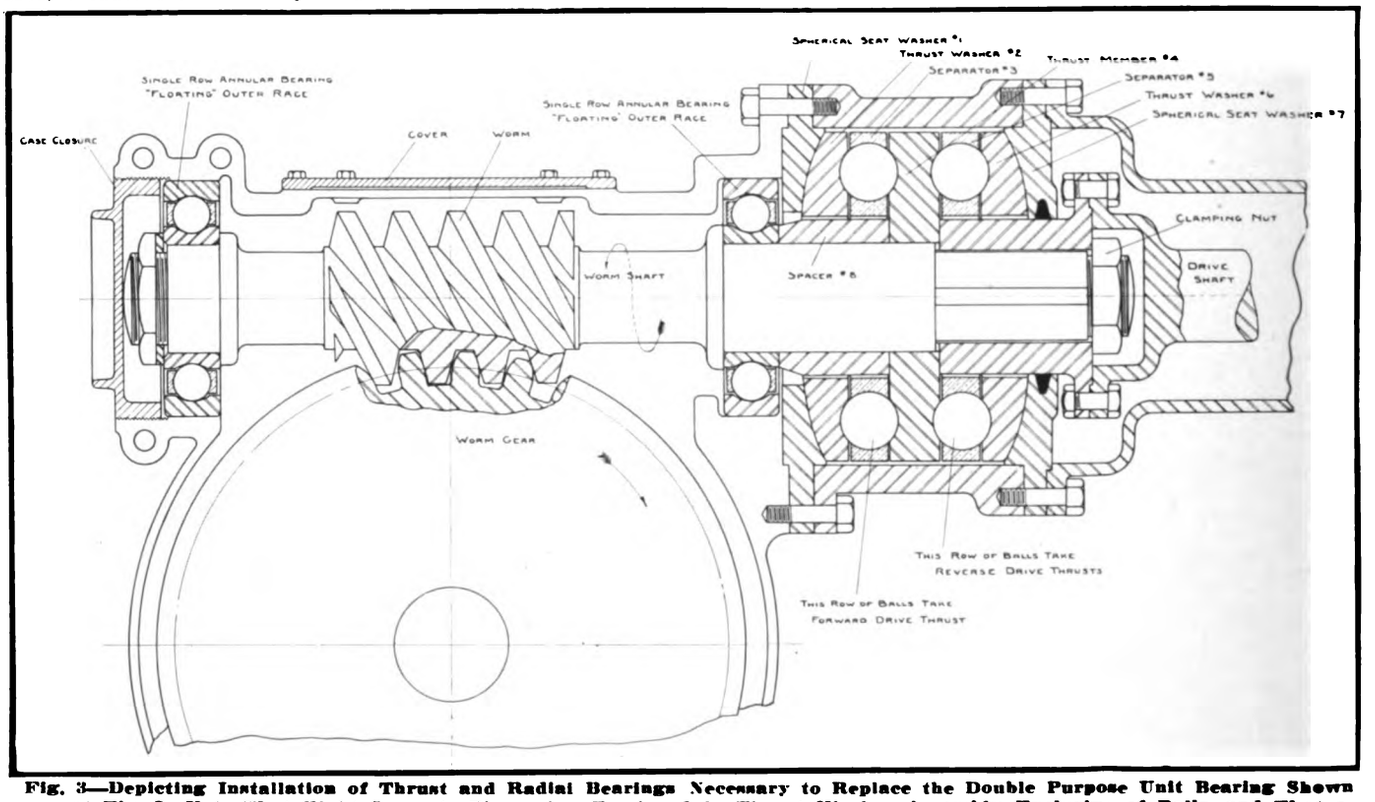

Fig. 3—Depicting Installation of Thrust and Radial Bearings Necessary to Replace the Double Purpose Unit Bearing Shown at Fig. 2—Note That Eight Separate Pieces Are Employed in Thrust Washer Assembly Exclusive of Balls, and That a Single Row Annular Bearing Must Be Used to Resist Radial Loads.

be too high for a truck of five tons capacity. As no attempt was made in the original article to consider anything but bearing mounting suggestions, it is not necessary to analyze too deeply a set of conditions relating to truck design or worm gear construction only assumed to make the main idea, that of bearing installation, clearer. For convenience in calculation, I have assumed a condition which does not exist in practise; that is the application of all the power at the rim of one driving wheel. This does not alter the reaction load on worm tooth because if two driving wheels were used, not only the weight to be moved and considered as resting on the rear wheels, but the useful driving effort, will have to be divided by two.

Take the other extreme case, where the tooth pressure would be greatest or when the reversing gear was engaged, we can arrive at the pressure at the worm pitch line by using the formula which follows:

$$P = \frac{63{,}025 \times H.P.}{R \times N}$$

Where—

R = Radius of worm,
N = Number of revolutions a minute.

Substituting known values we have:

$$P = \frac{60{,}025 \times 40}{1.5 \times 250} = 6722 \text{ pounds.}$$

The figures obtained by either method are very nearly the same, and if a pressure of less than 2000 pounds at the worm pitch line will drive the truck on the direct drive, and if this is a maximum that we can obtain from our 47 horsepower engine after losses are considered, it is difficult to see how a lever which decreases the load instead of multiplying it can exert more than a third of this amount at the point of contact of the wheel with the ground, under the conditions stated and shown at Fig. 1, herewith.

The load on the worm gear teeth cannot be taken as the amount of end thrust on the bearing, however, as it will be resolved into radial and thrust load components, the relative value of which will vary with the thread angle and the extent of which can only be determined properly by considering a carefully made graphical layout of the gearing in question. As a general statement, one may say that the thrust will vary from 90 to 75 per cent. of the tangential load, this depending upon worm tooth angle, and this is a high value.

Considering the thrust load to be resisted by the bearings, we will see if this is so high that it cannot be taken by a double purpose bearing of proper size. Take the thrust existing on second speed as a basis for selecting a bearing according to catalogue rating, the overload capacity of such a bearing being sufficient to cope with the greater but seldom occurring loads on the low and reverse ratios. Here we must consider

Digitized by Google

a 12 per cent. loss in the change speed gears before figuring the power applied to the worm. Instead of 47 horsepower which is applied to the front end of the gearset, we have 41.36 horsepower, delivered to the worm shaft at 500 revolutions a minute. To find torque at centre of shaft we use the formula:

$$P = \frac{63{,}025 \times \text{H. P.}}{N} = \frac{63{,}025 \times 41.36}{500} = 5213.4 \text{ inch-pounds.}$$

Dividing this by the radius of the worm we get a tooth pressure of 3475 pounds. Not all of this load is a thrust to be taken by the bearing, however. Taking the highest value, we can assume that the end thrust on second speed ratio is about 3000 pounds. The bearing to be used, if this be true, is one that will sustain 3000 pounds at 500 revolutions a minute.

If the conditions be as stated by Mr. Younger and a load of 6400 pounds is present when the vehicle is in intermediate gear, and considering that this is the amount of pressure that resists worm rotating, we must impart a little more than this to the gear by the engine in order to produce vehicle movement. This would mean that an entering torque nearly twice as great as that obtainable from the engine considered in this specific case would be needed, or that the engine power would need to be doubled to impart sufficient energy to the worm to drive the loaded truck, if this were the correct amount of pressure existing between the teeth.

The reason for the writer's previous remarks in replying to Mr. Thomas is just as Mr. Younger has surmised, and were due more to enthusiastic defense of the excellent features of the double purpose bearing than to proper reflection of the facts of the case in point. Mr. Thomas' statement that bearings should not be selected with reference to loads said to be present by the writer in the first article or they would fail in service, was correct, and I see no reason for questioning his estimate of maximum load on the stationary worm teeth, now that he has fully stated the conditions which are present at the time this load obtains.

Mr. Younger, at the other hand, goes on record in saying that it would not be possible to provide a double purpose bearing less than 12 or 15 inches in diameter to resist worm thrusts due to 38 horsepower torque and to support his contention he cites pressures twice as great as those the writer now believes to exist after revising the faulty figuring which led him astray in the first instance. If the writer's low estimate were an injustice to the power transmission qualities of worm gearing, surely Mr. Younger's statement based on "definite, cold blooded logic" which his years of experience have proven to be right, might be misconstrued by other readers, and double purpose ball bearings thought unsuitable for supporting worm gears, notwithstanding the fact that they have been used for this purpose with success.

If we consider, as is general practise, that the bearing should be selected with reference to thrust to be resisted on the intermediate gearing, we find that a double purpose bearing No. 415 having a 45-degree load line will sustain a thrust of 3000 pounds at 500 revolutions a minute. This bearing is considerably less than 15 inches in diameter; in fact, the outside diameter is 7.4803 inches. The bore is 2.9527 inches and it is but 3.25 inches in width. Ten 1.25-inch balls are used a row. This bearing, as shown in accompanying drawing, Fig. 2 (in which all parts are to scale), will replace the two thrust washers and the radial bearing depicted at Fig. 3.

To make the advantages more apparent, let us see what size ball thrusts of the conventional type would be needed. We find that a No. 2309 listed in Bulletin No. 25 of S. R. B. Company will take a load of 3510 pounds at 500 revolutions a minute. This has a bore of 3.5 inches and is 7.125 inches in diameter, 10 1.25-inch balls are used. Even if the construction of this type bearing permitted it to take axial loads in either direction, it would be necessary to use in connection with it a radial bearing to resist the radial component of the tangential load. However, it takes two of these in addition to the radial bearing to replace the double purpose member which the writer favors, and which will take thrust in either direction and carry radial load as well if properly mounted. The housing required for the double row bearing is just as designed for a plain radial annular bearing, and there is no possibility of disalignment between parts of the bearing. At the other hand, where ball thrust washers are used, they must be mounted in connection with spherical seat members, and if the worm expansion must be compensated for (a condition we are all agreed should be considered in designing) the problem of mounting involves some degree of engineering and construction skill, as evidenced by Fig. 3. In either case the thrust members are housed at the front end of the worm, the rear of the worm shaft being supported by a floating single row annular bearing of adequate capacity, and very easy to select from the manufacturer's lists without using excessively large members.

Mr. Thomas cites the maximum thrust pressure as unfavorable to a double purpose bearing. Under the conditions he states, where this load can exist only when the worm is stationary because of a braking effect, a single ball of the bearing recommended in this letter would sustain all of this thrust without being stressed to its elastic limit. I have determined the resistance to crushing of a 1.25-inch ball to be over 100,000 pounds in our laboratory, and surely 10 of these members, which do not vary more than .0001 inch from standard size will not be stressed alarmingly when at rest, by this load, even considering that the load line is angular rather than horizontal.

Judging from both the letters sent you, all my remarks pertaining to lubrication which applied specifically to plain collar types of thrust bearing, have been misconstrued to be detrimental to proper worm gear lubrication, which was not my intention. I do not need to look into a worm gear housing to see that proper lubrication is possible. My only contention was that if the pressure of 30,000 pounds were present while the worm was turning, it would be very difficult to force lubrication between surfaces held together by this force.

As other remarks in Messrs. Thomas' and Younger's letters are evidently based on misinterpretation of my meaning, I do not think it necessary to take any more of your valuable space in discussion. After all, the main point at issue was the suitability of the double row bearing of practical size to resist the thrusts of worm gearing, and not lubrication or design of worm gearing. If my reasoning be correct, I feel that I have shown it possible to save by using double purpose or unit bearings in place of combination mountings. As this has proven to be the case at all other bearing points of the automobile where both thrust and radial loads exist, I cannot see any reason why it does not apply to worm gearing as well. If my final analysis of the loads obtaining (which even now are approximations), based on formulae considering entering torque, are incorrect and the high thrust loads stated by Mr. Younger are present while the gearing is in operation, then the case is one extremely unfavorable to any form of anti-friction bearing except those of extremely large size.

I trust that this letter of explanation may make my line of reasoning sufficiently clear so that further controversy will be unnecessary, as the matter now resolves itself merely to one of differences of personal opinion, which are by no means rare when questions involving machine design are considered.

With a final apology to Mr. Thomas for my previous unwarranted attitude, I beg to remain,

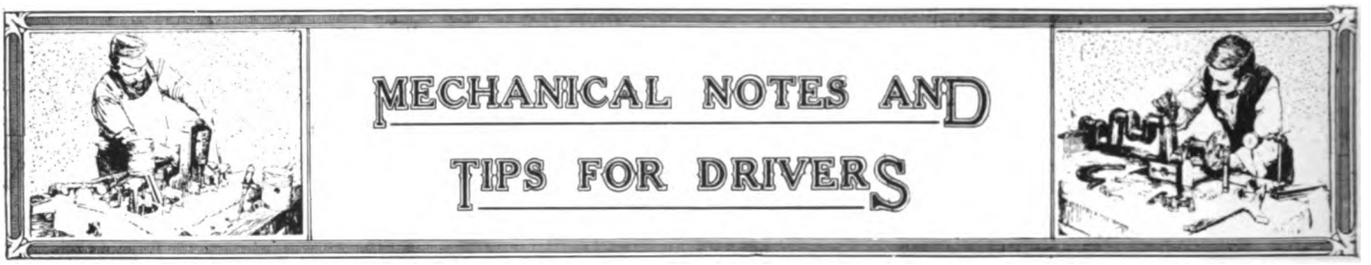
Yours very truly,

VICTOR W. PAGE, M. E.

Bristol, Conn., Feb. 6.

WHITE OPENS NEW SERVICE BUILDING.

The new service building of the White Company, Cleveland, O., in New York City on West 57th street, between 11th and 12th avenues is completed and is in operation, and the location is ideal, being in the centre of the commercial district. The structure is one story but has 25,000 square feet of floor space, and a feature is the absence of posts or pillars, the roof being supported by trussed spans. Overhead lighting is employed by means of large skylights. The department for the maintenance and repair of motor cars is very complete, including a modern machine shop, carpenter shop and a large stock room in which is carried a complete line of White parts.



H. R. RADFORD HAS NEW POSITION.

Harry R. Radford, who for several years has held the position of general sales manager for the Cartercar Company, Pontiac, Mich., has assumed the management of all its interests except the manufacturing department. The change follows the resignation of R. A. Palmer as general manager. Although there was considerable speculation as to who would succeed Mr. Palmer, Thomas Neal, president of the General Motors Company, of which the Cartercar Company is a constituent, announced that it had been decided to dispense with the position of general manager. Mr. Radford will have charge of the advertising, selling, credits of agents, etc., and the directing of the seven Cartercar branches in the leading cities.

BOSCH SERVICE STATIONS.

Arrangements for special installation service have been made in all branches of the Bosch Magneto Company, New York City, so that operators of motor vehicles in the vicinity of any branch, desiring to have their present ignition systems changed to that of the Bosch, may leave their cars and have the change effected promptly and at a reasonable figure.

STEERING WHEEL COVER DEVICE.

Although different forms of gloves are worn, many automobile operators complain of cold hands during the winter. One of the reasons for this is that in gripping the wheel the circulation of blood is more or less impeded by the pressure exerted in holding the member. Some drivers find that the old-fashioned woolen mitten is the warmest covering for the hands, but more or less difficulty is experienced in gripping the wheel because of its smoothness.

Some drivers wrap the wheel with friction tape, and while this material eliminates smoothness and permits the use of mittens, it is extremely cold. At Fig. 1 is presented a method of wrapping the circle with felt which will not only exclude the cold but absorb vibration as well, making long drives much easier of accomplishment. To prevent the cloth from slipping, tape is employed as depicted in the

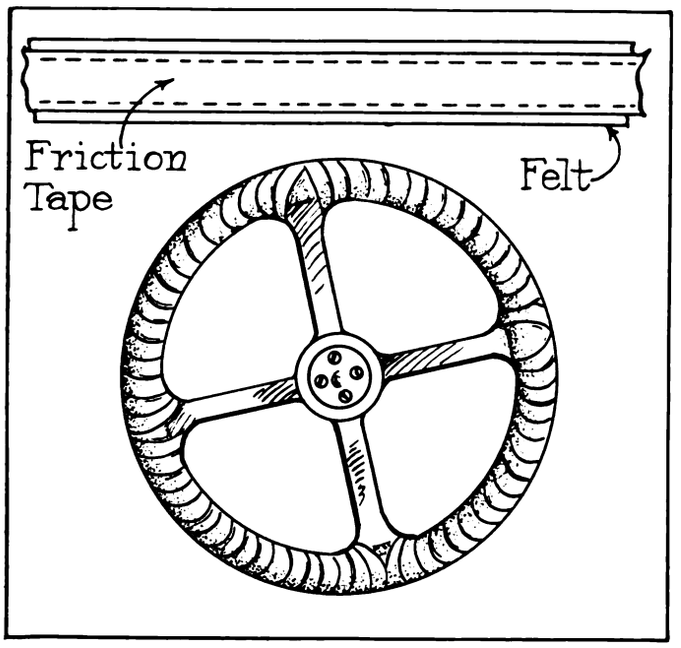

Fig. 1—Depicting How a Wheel May Be Wrapped with Felt Sewed to Friction Tape.

drawing. This cloth is sewed to the felt and should be less in width than the softer material.

The first step is to cut the felt into strips of about .75 inch and sew together as many as will be necessary. The tape is then stitched on and the rim of the wheel covered as outlined. In placing the covering on the wheel the edges of the felt should be wrapped closely together to provide smoothness. When the circle is covered the two ends are sewed together. The tape will grip the wood firmly and being fastened to the cloth will prevent the latter from moving.

SUGGESTIONS FOR VALVE TIMING.

To obtain the greatest efficiency from the internal combustion motor the valve and ignition timing should be correct. In the previous issue of MOTOR TRUCK the latter subject was discussed and the various methods of correcting faulty operation outlined. The average driver hesitates to attempt the correction of the valve setting, and although absolutely accurate adjustment is a delicate task, requiring as it does the expert, considerable improvement may be effected by the novice.

Generally speaking, with the modern motor there is little to cause the valves to become out of time, but wear at a number of points, such as cams, rollers, tappet rods, plungers, etc., will bring about a loss in power. The constant hammering of the tappet against the valve stem sometimes results in these being flattened out, causing the valve to open too late and close too early, or not lift high enough and thus retard the flow of gas to the cylinder. Excessive wear of the teeth on the crank and camshaft, or if either be loose, will affect the operation of the cams and consequently the timing, but with the large gears such as are now utilized in motor car construction, the amount of wear taking place will not make any great difference. And it may be stated also that considerable improvement has been made in the design of valve mechanism, eliminating much of the former troubles.

The correct opening and closing of valves is marked on the flywheel by the majority of manufacturers. These figures and their application puzzle the novice, but are understood easily if the motor's cycle of operation be taken into consideration. The figures, 1, 2, 3, 4, represent the cylinders while the letter I means the intake valve, and E designates the exhaust. Thus, the marking I, O, 2, 3, signifies the opening point of the intake valves of the second and third cylinders. Another set is I, C, 2, 4, which denotes the time the intakes close. When the letter C is employed alone it indicates centre.

The explosions of a four-cylinder, four-cycle motor do not take place in consecutive order; that is, the arrangement of the crankshaft is such that two pistons are up and two down at the same time, as will be noted at Fig. 2. In this instance the first cylinder, usually that nearest to the radiator, is about to be ignited by the spark while the fourth is about to take in a charge of gas. The pistons in the second and third cylinders are nearly at the bottom of the stroke and these are exhausting and compressing, respectively.

The order of firing is 1, 3, 4, 2, and it will be seen that the first to explode is No. 1, the next No. 3 and the last is the second cylinder. This order may be 1, 2, 4, 3, according to the design of the engine. In either case, however, there are four strokes of the piston and two revolutions of the crankshaft to bring about one impulse or firing stroke. By referring to the firing order below the illustration it will be noted that the sequence of the strokes is: Firing, exhaust, compression and suction of cylinders 1, 2, 3 and 4, respectively. By utilizing these tables one may become familiar with the order of explosions and these figures may be employed in timing where the flywheel is not marked.

Where wear has taken place at the tappet or valve stem, and these members are adjustable, the efficiency of

Digitized by Google

the motor car can be improved greatly by resetting to conform with the figures on the flywheel, previously mentioned. The usual method is to lengthen the tappet until an ordinary business card may be inserted and while this is commendable a better way is to utilize the figures upon the flywheel.

Many makers fit an indicating arrow or pointer to the motor, this device being installed to facilitate the operation of timing. If the engine be not thus equipped a mark may be made upon the centre of the cylinder or upon the dashboard.

As has been explained, the crankshaft makes a half revolution to each stroke. Referring again to the drawing, it will be seen that the first cylinder is about to fire and that both valves are closed. The exhaust of the second is about to open. If the timing be correct, the indicating arrow will point to the marking E, O, 2, 3. If late, these figures will pass by the indicator and the exhaust tappet of

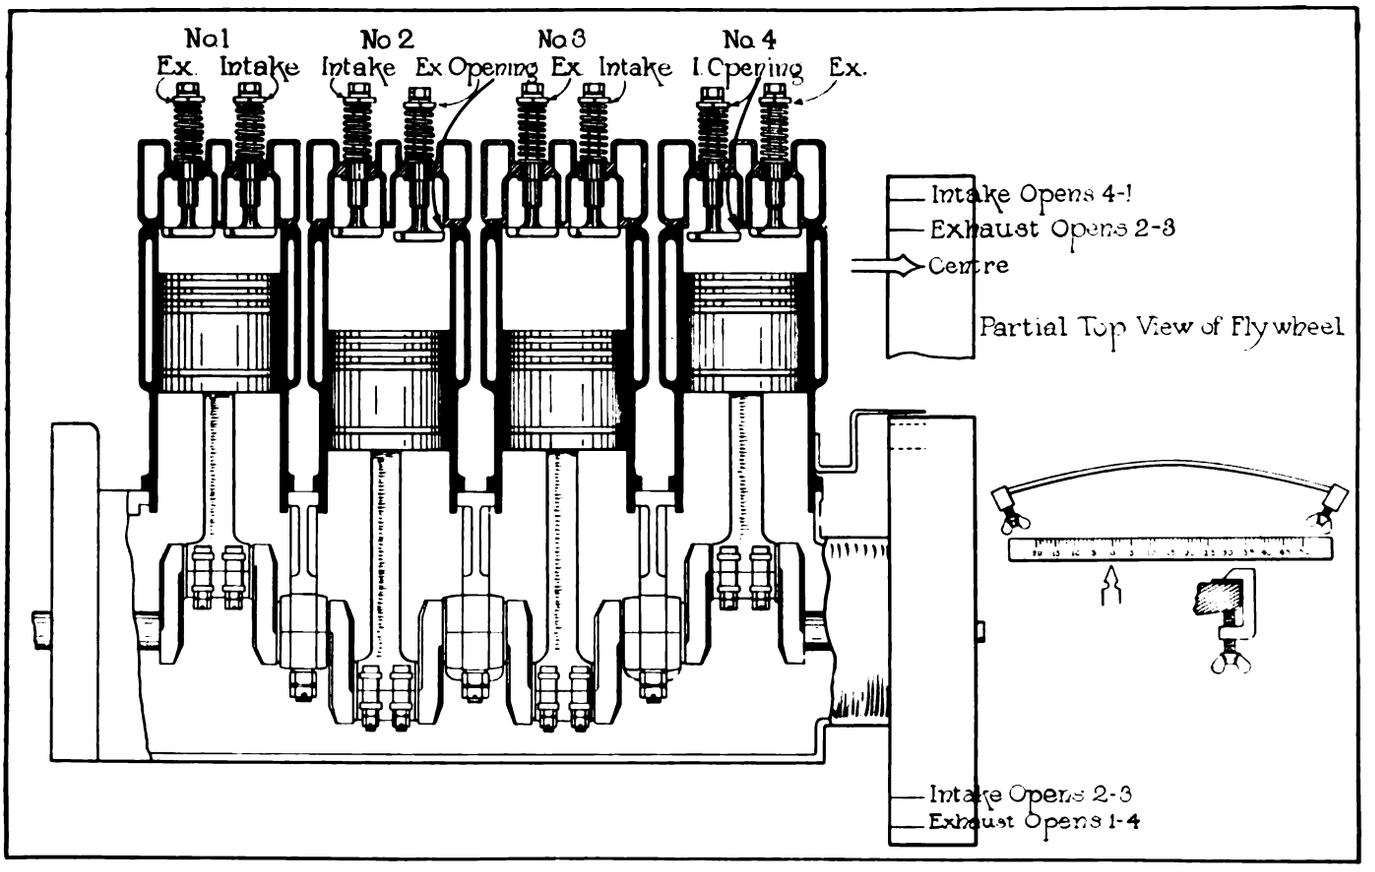

Fig. 2—Illustrating How Valves Are Timed and Tappets Adjusted by Utilizing the Markings on the Flywheel.

4—Compression	Firing	Suction	Exhaust

the second cylinder should be adjusted until the valve starts to open or lift in the line.

Moving the flywheel slightly, the marks I, O, 4, 1, should appear as the intake valve of the fourth cylinder starts to lift, and if it does not, this should be adjusted. The flywheel is now given nearly half a turn when the marking for the exhaust members, 1 and 4, and intake, 2 and 3, will appear and can be regulated.

Some makers include the closings on the flywheel and these also can be checked, but many simply mark the openings as too many figures are apt to confuse the amateur. It is not a good plan to attempt improving the setting of the valves as marked by the manufacturer for the motors are thoroughly tested and valves timed to give the best results intended by the designer.

Where the flywheel is not marked, the timing will have to be secured from the factory, but a gauge that will prove useful in timing valves from the crankshaft is shown in the sketch. The device consists of a piece of brass about .0625 inch thick by one wide. As the diameter of the average flywheel is approximately 15 inches, a foot of metal will be sufficient. The fraction of an inch that equals a degree is figured out and marked on the brass as depicted in the drawing. The degree can be ascertained by calculating on the basis of 360 degrees to a circle.

In using the instrument the top and bottom centres of the flywheel are located. This may be accomplished by inserting a rod through the opening in the compression cock or by removing the lower half of the crankcase, or an inspection plate, to ascertain when a piston is at the bottom or top of its stroke. The rule is then laid upon the flywheel with zero mark under the usual pointer or arrow. The points are then marked off or compared. The device can be fastened to the flywheel by clamps as indicated in the illustration.

All correction of timing should be done when the motor is hot in order to secure the best results. The relief cocks should be opened to reduce compression so that the flywheel may be rotated easily. If the motor be not equipped with these devices the spark plugs may be removed. The adjustment of the valve openings is a simple matter and the operation will be facilitated by studying the accompanying illustration, which was so drawn as to make clear the valve openings and their markings upon the flywheel.

CONSTRUCTION OF SOLID MOTOR TIRES. *

By Charles B. Whittelsey.

SOLID motor tires can wear away and suffer as much from misuse as the pnuematics, and it has been said that lack of knowledge of them lies largely with the manufacturers by their never educating, to any extent, the users of their product to an appreciation of the tremendous difficulties that have been surmounted in arriving at the present state of efficiency—or of the endless amount of experimental work they have done, and the discouraging setbacks that they have had in their efforts to place at the disposal of the public the solid motor tire of today.

Historical.

It is uncertain when or where solid tires were first used for wheels on vehicles. However, their use was not common until after the year 1881, when the Carmont tire was first employed on hansom cabs on the streets of London. The tire adopted was Carmont's patent of 1881 in 1883—"a rubber tire held in rolled steel channels in a state of compression between converging flanges."

The Carmont was the first solid tire introduced in America, by the late Channing M. Britton of the important New York carriage firm, Brewster & Co., for which Mr. Britton obtained the American right under the Carmont patent. Several manufacturers made tires for them.

The next practical advancement in the development of the solid tire made in America was under the patent granted to A. W. Grant in 1896, later known as the Kelly-Springfield. This tire being seated in a rim channel with diverging sides there was no loss of resilience from the compression of any part of the rubber. The channels were not as deep as in the Carmont type, and a larger percentage of rubber was available for wear. The rubber body was held into place by means of circumferential wires running through it and forming circles of smaller circumference than the rim flanges. Since the introduction of the Grant patent the use of solid rubber tires has increased steadily.

The Victor tire was similar in shape and construction to the Carmont and Grant, but the retaining wires were incased in leather to prevent their cutting the rubber. Later on, these wires were covered with specially woven fabric.

The next patented tire which was developed to any great extent was the side wire—a tire held into position by two endless circumferential wires sprung over the edges of the channel which engaged the ends of embedded cross bars, thus holding the tire securely in the channel.

These and many other solid vehicle tires were made and used on cabs, carriages, etc., until the vehicles became motor driven. The weight and speed of the motor vehicles increased as well as their carrying capacity, which made this style of tire altogether too light to perform the work required of it. This condition brought about the invention of the solid motor tire—a tire vulcanized in circular endless form to fit the dimensions of a wheel. This type has been brought out in different designs, such as a flange, internal wire, side wire, hard rubber and metal base; also the demountable.

Construction.

Vehicle tires were made in oval shape, in cross section from three-quarter inch to two inches, advancing one-eighth inch between sizes, and of compounded rubber which is forced through a tubing machine die, vulcanized in long molds with many cavities in the shape in which it has been designed. These tires were cut in lengths to fit the wheels and internal wires were inserted, of such lengths as to allow them to be spliced when applied to the wheel. The tires were then put into position in a channel on a wheel and held by mechanical devices while the ends of the wires were brazed together, the rubber having been pushed back, affording the wires sufficient space to allow this brazing process.

What is known as the cushion solid, which is perfectly round molded rubber in similar form, with a single hole through the centre of same for retaining wires, was put into use about this time.

The construction of the solid motor tires that have been put on the market up to the present time is very similar in a general way. The rubber is forced through a die of a tubing machine, or built up from thin sheets of calendered stock in endless form to fit the exact dimensions of a wheel, on a particular style of base or retaining body of the tire, as designed by the different rubber manufacturers, according to their various ideas of efficiency, which have taken various forms, such as circumferential and side retaining wires, which are engaged over embedded cross wires; base of hard rubber in various forms, also of semi-hard rubber which can be molded into the tire, and more recently, the plain metal base types which are most successful.

The rubber portion of a solid motor tire is usually about 2.75 inches high, and varies in width according to its design. The tire is built so that when it is applied over the steel band of the felloe of the wheel it fits so snugly that it has to be forced on with a press specially designed for this purpose. This is done so that the tire will not creep circumferentially or laterally. When the tire is in position on the wheel, it is further secured by steel flanges bolted on each side of the wheel, also to prevent its creeping or working off the wheel.

The side wire motor tire is built in similar shape, but cross wires are inserted throughout the base of the tire at stated intervals. It is placed in a channel made for this purpose and side endless circumferential wires are applied on each side of the tire over the ends of the cross wires in the base, which holds it in position in the channel. The tire in the channel is applied over a wood or steel band on the wheel.

Metal base tires are built up of compounded rubber in graduated consistencies from the hard base which forms their inside circumference next to the steel base to which it is vulcanized, to the resilient rubber that forms the wearing part of the tire. This rubber tire is vulcanized to a steel tire band which is applied by pressure to the wheel over the steel felloe band with either a hydraulic or specially built press. It requires from 60 to 90 tons pressure to apply these tires to a wheel and it has often been found necessary to use more than 90 tons to remove tires so applied. This frictional contact makes it unnecessary to use any side flanges or other fastening.

Size and Shape.

The size, shape and dimensions of these types of tires are varied according to the designs of the manufacturers—no two being the same in any of these particulars. The service obtained from a given diameter and cross section is as varied as the different types. The reasons for this can be attributed to the variation in the cubical contents of the cross section of the tire, some designs having a much greater amount of rubber than others, and, therefore,

*Extract from paper read before recent meeting of the Society of Automobile Engineers.

Digitized by Google

the distribution of pressure over the different sizes of tires caused by the intensity of pressure a square inch brings a greater or lesser area of the tire in contact with the road, and as it is only that part of the solid rubber tire which is in contact with the road that is carrying the load, the tire with the greater area at this point performs the more satisfactory service.

The height of the rubber from the tire seat governs largely its elasticity and cushioning effect. A tire too high and narrow cannot stand up under a heavy load. It will weave from side to side. A tire worn down to a short distance from its non-extensible base loses its cushioning effect, and instead of the uneven conditions of the road being absorbed by the rubber, the tire is hard and transmits the shocks of bumping over it to the truck, and soon racks the truck and its motor, so that repairs become necessary.

Life of Tires.

The life, strength and durability of the tire lie primarily within the compounded rubber of which it is made, and also its construction. Other conditions being equal, the tire made of the highest grade of rubber has the longest life and is the most resilient. Certain minerals are added to give it strength and durability, the quantities being varied according to the best judgment of the tire manufacturer. The proper size tires which are dependent on the speed of the vehicle, applied on an electric truck driven at eight or 10 miles an hour, will give greater mileage and much longer life than the same size tires on a gasoline truck driven from 12 to 15 miles an hour. The carrying of a ton at a speed of 10 miles an hour is a very different proposition to a tire than carrying the same amount of load at 15 miles an hour. Greater mileage can be obtained from tires run in a city devoid of grades.

Heat is the result of motion, and as the tire when in motion is continually being pounded between the road and the steel band of the wheel, it develops a greater amount of heat within itself, which is transmitted throughout the tire, and has a tendency to shorten the life of the compounded rubber. The heat developed in solid tires is much less in the fall and winter and spring of the year owing to the cold roads, water, snow and ice. The number of months' service, as well as the mileage, that a solid tire may give is influenced by the same condition; also by the weight the truck has to carry, the speed at which it is driven, and the nature of the country where it is used.

Driving Wheel Diameter.

Tires on wheels of greater diameter give longer and better service, because of the greater area of rubber in contact with the road, as well as the fact that they do not have to travel so fast, and, therefore, do not generate as much heat, or deteriorate so rapidly. Neither do they travel so far and wear down as rapidly as the tires of smaller diameter. Actual experience has demonstrated that big wheels and tires are better on heavy grades in particular.

Tires for Electric Vehicles.

A solid motor tire for an electric truck must be made from a compounded rubber stock which is soft and most resilient. It must absorb the unevenness of the road, and resume its normal shape instantly, so as to lessen the traction of the vehicle. By the absorption of the shocks the consumption of electric current necessary to drive the truck is reduced to a minimum. This is largely dependent upon the resiliency of the compound, as well as the shape and size of the tire.

Many shapes have been tried out for use on electric trucks—the standard oval shape prevailing. The corrugated or grooved treads present less road contact and assist in preventing skidding. Tires molded with these grooved treads and under-cut webbed sides afford an additional cushioning effect and are very successful on electric vehicles. The styles of tires used on electrics are the same as those offered for other classes of vehicles. The size of the cross section also affects the cushioning qualities of the solid motor tire on electric trucks, and a fair comparison cannot be drawn between two makes of tires, one of which is approximately eight square inches in area for four-inch section, and the other 10 square inches; for the one with the greater area will cushion and carry a greater load, absorb the shocks better, give longer life, and better service.

The life of the tire on electric vehicles is much longer than on gasoline machines—due partially to the low speed on the vehicle. From this class of vehicle being run at lower speed, it is handled with much more care than a high speed truck; therefore, unknowingly, the tires receive more consideration.

Dual or Twin Tires.

Dual or twin tires are applied on the rear wheels of trucks built to carry heavy loads, and subjected to the most severe strains, as it is known that when these dual tires are of the proper size they have greater sustaining power from the distribution of the load over the two tires on a single wheel. However, it is frequently demonstrated that one of the twin tires gives out before the other—due to the fact that they have been driven over uneven roads where one of the tires on the wheel has had to carry the entire weight of its wheel a greater portion of the time and has given out from being overloaded.

Block Tires.

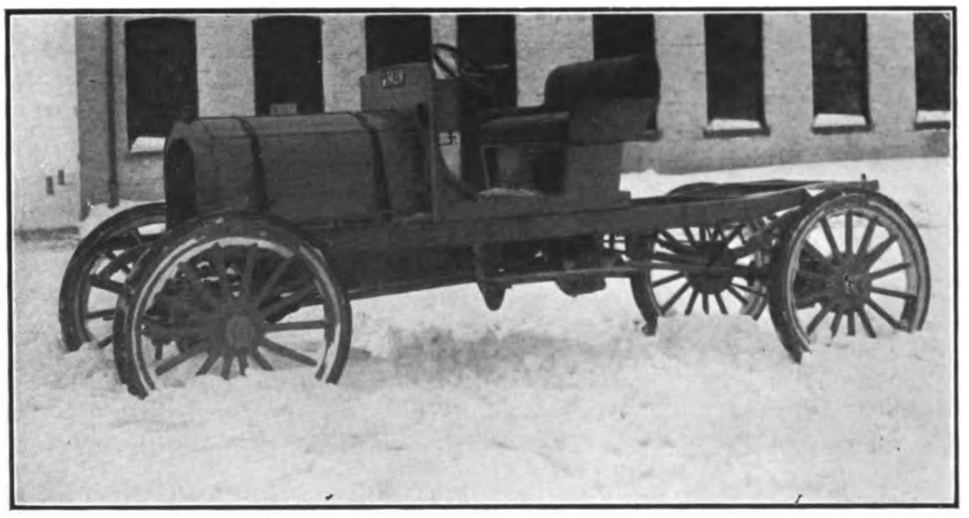
Block tires are sections of solid tires vulcanized to steel plates or held in position by steel sectional frame fitting over the blocks of rubber with a wider base, or protruding wires in the base. This style of tire is used principally in duals on the rear wheels of the larger motor trucks subjected to most severe work. When driven rapidly, there is but little unevenness of motion felt from the tire being so constructed. It does not generate heat within itself as rapidly as a solid tire, owing to the fact that there is a space of an inch or more between the blocks which enables the rubber to yield more as it rolls up ahead under the travelling load. There being no communicating rubber between the blocks, the heat is confined in each block, which can be removed or replaced when it is injured or worn.

Block tires afford a very good non-skidding quality, and are excellent on soft roads, as there is but little slipping in wet, slippery places. In winter the spaces between the blocks pack with snow and ice, and the tire then loses its non-skidding and gripping effect. In all seasons the block tire picks up stones between the serrations, and these small stones embed themselves in the rubber, and should be taken out with a strong screw driver or any other similar tool before they have time to cut and work into the blocks of rubber.

Demountable Tires.

The demountable solid motor tire has been too long delayed. The cost to the tire maker, truck manufacturer, and the truck owner, of the delay of laying up the truck while the wheel is taken off and sent by express to the nearest branch or factory of the tire manufacturer and the old tire taken off and the new one applied is entirely too great. This expenditure of time and money will be avoided when tires are all demountable and interchangeable like pneumatics for the pleasure car.

Tire Troubles.



The greatest of solid motor tire troubles is the separation of the tread from the base before the tire has given satisfactory mileage. While some of the troubles have been due to the construction of the tires, the principal causes

Digitized by Google

have been overload and overspeed. The truck manufacturers have not equipped their trucks with tires sufficient in size to do work demanded of them. The tendency is to under-rate the overload that is going to be put on the truck soon after it is turned into service, just as in the case of pleasure cars until recently. Sufficient allowance has not been made for the portion of the load that is carried on the rear wheels, and trucks are daily equipped with undersize tires that will go to pieces within 2000 or 3000 miles instead of lasting 6000 or 7000. Truck manufacturers will some day learn that the reputation of their trucks for "eating up tires" costs them more than the difference in cost between undersized and proper size tires—a great many times over.

Standardization.

This point leads us to the standardization of the tire and wheel dimensions and fastenings, which was accomplished by the Society of Automobile Engineers on July 15, 1911. What does this mean to the tire manufacturer? The expenditure of thousands of dollars to make an entirely new equipment in which to make his solid tires to conform with the new dimensions that the S. A. E. standardized. What does this mean to the wheel and truck manufacturers?

Four Wheel Drive Truck Purchased by Government for Quartermaster's Department and Which Participated in Army Manoeuvres at Washington.

A saving of thousands of dollars, instead of having to carry as many wheels in stock as there are varieties of tires to fill an order for any given size. The S. A. E. standardization has reduced this to one wheel for any make of tire for any given size.

The time will come when the cubical contents of the tire will be standardized, also the demountable fastening, so that the difference in service of any given size tire will be measured by the difference in the quality of the compounded rubber that it is made of by the different tire manufacturers.

Conclusion.

The pneumatic and the solid motor tires have made the development of the pleasure car and motor truck possible, and yet they have been given less serious consideration than any other part of the equipment. A given amount of rubber and fabric can perform only a measured amount of work, the same as steel and other products, and when it is overtaxed its life is shortened exactly in proportion to its abuse.

FIRESTONE ISSUES TIRE BOOK.

Any information relative to the care and maintenance of tires is appreciated by the owner and operator of mechanical transports. The Firestone Tire & Rubber Company, Akron, O., is issuing a booklet entitled "Minor Repairs and the Care of Tires." As the title indicates it describes the best methods for making repairs to tires and inner tubes and the brochure also contains a number of suggestions on their care and preservation. The booklet will be sent free upon written request to the Firestone Tire & Rubber Company, Akron, O.

GOVERNMENT TESTS FOUR WHEEL DRIVE.

Announcement is made by the Four Wheel Drive Auto Company, Clintonville, Wis., that it has constructed and shipped to Washington, D. C., a 1.25-ton truck which is to be utilized in the army manoeuvres planned by the government. The order was the result of a visit to the factory by a representative of the War Department who subjected the machine to severe tests. Owing to the short time allowed in filling the order, the company was obliged to fit the chassis with a remodelled touring body as depicted in the accompanying illustration, the picture being taken on the day of shipment.

The vehicle is propelled by a four-cylinder, four-cycle, water-cooled motor having a 4.75-inch bore and 5.5-inch stroke, and rated at 45 horsepower. A multiple disc clutch is fitted and a sliding gear transmission, back of which is a sub-transmission consisting of Morse silent link chain and gears. Inside the driven gear is placed a differential, from which two shafts drive to bevel gear differentials on both axles, all four wheels driving.

On the shafts, near the sub-transmission, is a patented locking device, one for each member, which are utilized as an emergency device for operating an opposite pair of wheels in the event of serious damage to either shaft or axle. Both axles are of the full floating type and the front member is fitted with the Four Wheel drive patent with ball and socket steering joint enclosed, and the universal joint permits the machine to be driven and steered by the front axle arrangement.

NEW DEPARTURE BALL BEARING DATA.

The New Departure Manufacturing Company, Bristol, Conn., maker of ball bearings of that name, is mailing the trade an interesting 76-page catalogue, the contents of which give valuable information of technical character pertaining to ball bearings. The book will be mailed on request to manufacturers, purchasing agents, designing and mechanical engineers. The New Departure Company suggests that applications be made upon the letter head of the firm with which the person is connected.

PLATINUM RISING IN VALUE.

The price of platinum is rising, this being due, presumably, to the enormous demand for the material in automobile construction. According to an official of the Remy Electric Company, Anderson, Ind., the material was quoted recently at $650 a pound in Berlin, Germany, which is one of the centres of the platinum trade of the world.

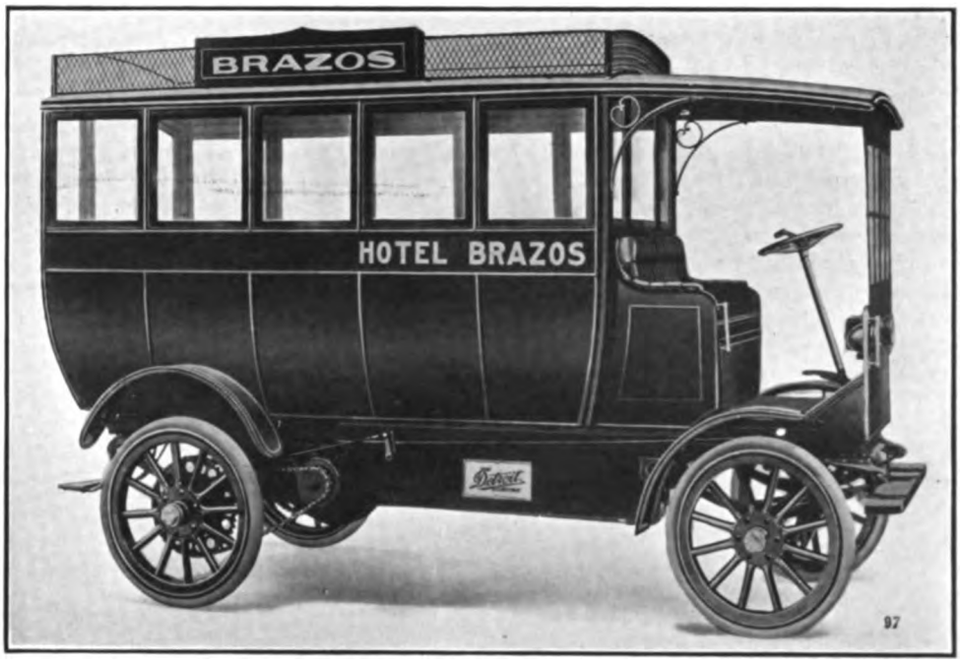
ELECTRIC VEHICLE BREVITIES

The mechanically propelled vehicle is rapidly replacing horse drawn equipment for transporting hotel guests to and from railroad stations. Not only is the service more comfortable but considerable time is saved and the progressive hotel men find the automobile useful for various other purposes, such as hauling supplies and carrying guests on trips to places of interest in the neighboorhood. The accompanying illustration presents a Detroit electric hotel 'bus, made by the Anderson Electric Car Company, Detroit, Mich., and placed in service recently by the Hotel Brazos, Houston, Tex.

The vehicle provides seating capacity for 14 persons in addition to the driver and the feature of the body is the placing of a roomy luggage rack on the top. This not only does away with the blocking of the aisle, an annoyance to the occupants of the car, but permits of carrying the baggage on the same trip. The rack is reached by means of a ladder.

The windows of the machine are of French plate glass, arranged so as to be dropped in warm weather and equipped with an anti-rattling device. The interior is lighted by electricity and the chassis is suspended on well designed springs insuring easy riding qualities. The battery, which is located amidships, consists of 60 A-6 Edison cells. Final drive is by side chains to wheels which are fitted with solid tires, 36 by four inches. The front members are also single, solid, 34 by 3.5 inches. The speed of the automobile is 11 miles an hour. One of the features which attracts the attention at night is the use of an electrically illuminated sign on either side of the luggage rack.

★



Day Baker, New England manager of the General Vehicle Company, Long Island City, N.Y., gave a stereopticon illustrated lecture before the New England Foundrymen's Association at Boston recently. He showed a large number of pictures presenting the progress of the electric vehicle from 1886 to the present. Of particular interest were the illustrations of baggage and factory trucks, six of which have been installed in the North station at Boston. The devices for factory work are operated at a moderate speed and are capable of carrying a very heavy load. A form of carrier utilized by large beef dealers also was explained and illustrated.

★

Realizing that the electric commercial and pleasure vehicle are entering upon a new era of prosperity and that the use of the former will be very largely increased throughout the country, the Westinghouse Electric & Manufacturing Company, Pittsburg, Penn., has mapped out an extensive campaign for the more general use of its electric motors for vehicles of all kinds.

At present about 24 makers are using the Westinghouse motor as a standard equipment. The concern has made a specialty of motors and controllers together with charging apparatus for batteries, for years, and it is the plan of the company to give every prospective owner of an electric vehicle the service of the Westinghouse Company regarding expert advice on the different kinds of equipment. This service will also be given freely to garage men, trucking companies and manufacturers who desire the opinions of the consulting engineer.

Standard vehicle motors are made in different forms for commercial vehicles including everything from those employed in transporting baggage in railroad terminals to the heavy duty types for trucks. The proper selection of a motor requires a careful study of a number of factors, of which the most important are: The character of the vehicle, its speed, the method of drive, and maximum weights when empty and loaded.

Detroit Electric Hotel 'Bus Which Was Placed in Service by the Hotel Brazos, Houston, Tex., Recently—The Vehicle Is Fitted with Electric Sign and Luggage Carrier on Top.

The first electric commercial vehicle to be constructed in Youngstown, O., was completed recently by the Youngstown Electrical Garage Company, the firm being composed of A. F. Clauss and Fred McVean. The machine has a carrying capacity of 1000 pounds, is capable of attaining a speed of 15 miles an hour, and is said to obtain 65 miles on one charge of the batteries. The price of the new car has not as yet been decided upon. Orders have been received for five machines and it is said the company will move into larger quarters.

★

After an experience of several years in designing, building and maintaining commercial vehicles, the Walker Vehicle Company, Chicago, Ill., has brought out the Walker balance drive for which is claimed simplicity, reliability and efficiency, as well as the elimination of

Digitized by Google

chains, shafts, etc. The power plant is all enclosed in the hollow rear axle and rear wheels and it is said this arrangement is not affected by load or road conditions, and

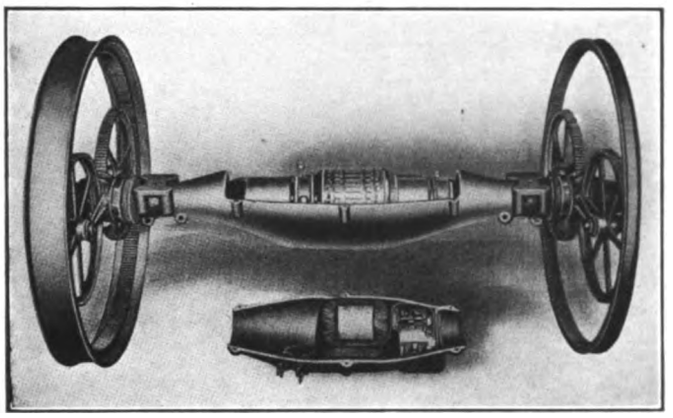


Fig. 1—Showing Compact Power Plant and Construction of Walker Balanced Drive.

that all moving parts are in perfect alignment, fully enclosed, dirt proof and very accessible.

A single motor is employed, this being housed in the rear axle, and power is transmitted through the directly connected differential and the two drive shafts extending from sockets in the differential into each rear wheel. Each shaft is equipped with a pinion at the wheel end and transmits the energy through idler gears to the large rim gears fastened to the tire rims of the wheels as will be noted in Fig. 1. Two idler gears are utilized in each wheel. The one differential is directly connected to one end of the hollow armature shaft.

The operation is obvious. The motor and direct differential drive the shafts, the pinions of which impart motion to the wheels by means of the idler and the rim gears. The drive pinions and shafts have no bearings except the teeth of the idler gears between which the pinions float in a balanced manner, this making for durability.

The motors are designed to meet the severest demands, and are said to be of ample capacity to perform the work continuously with the greatest efficiency. The hollow armature shaft runs in large imported Hess-Bright ball bearings. As will be noted, the motor, differential and drive shafts are all on the centre line of the axle and the power is developed on the centre of the axle and transmitted in balanced, opposite directions to each wheel.

The rear wheels are of special design, of ample diameter, and enclose the driving mechanism. The sides are formed by two pressed steel discs with radial corrugations in the form of spokes, which, in combination with the dished shape of the discs make for great strength and durability. They are mounted on Hess-Bright ball bearings of ample dimensions. The wheels are partly filled with lubricant, which is distributed over the working parts continuously when running and being oil tight prevent dust and dirt from entering as well as accumulating on the exterior. Drain plugs are fitted for the purpose of replenishing the supply or removal of old lubricant.

The disc type wheel is also utilized in front and these are mounted on Timken roller or Hess-Bright ball bearings. The front axle is a one-piece drop forging of I beam section type. The steering knuckles and front wheel stub axles are integral drop forgings of nickel steel and the use of Timken roller bearings not only makes steering easy but reduces wear and permits of adjustment.

On the standard design a triangular reach of channel section steel extends from the extremities of the front axle to the chassis frame where the two ends unite in a ball joint, this arrangement, which is depicted at Fig. 2 D, providing an extra bracing as well as absorbing road shocks, and the ball joint permits the axle to assume any angle which the road surface necessitates.

The Exide battery is furnished unless otherwise specified by the purchaser, and is located amidships, being supported by substantial steel cradles. It is accessible through a trap door, also side doors on either side of the container, this facilitating examination of cells.

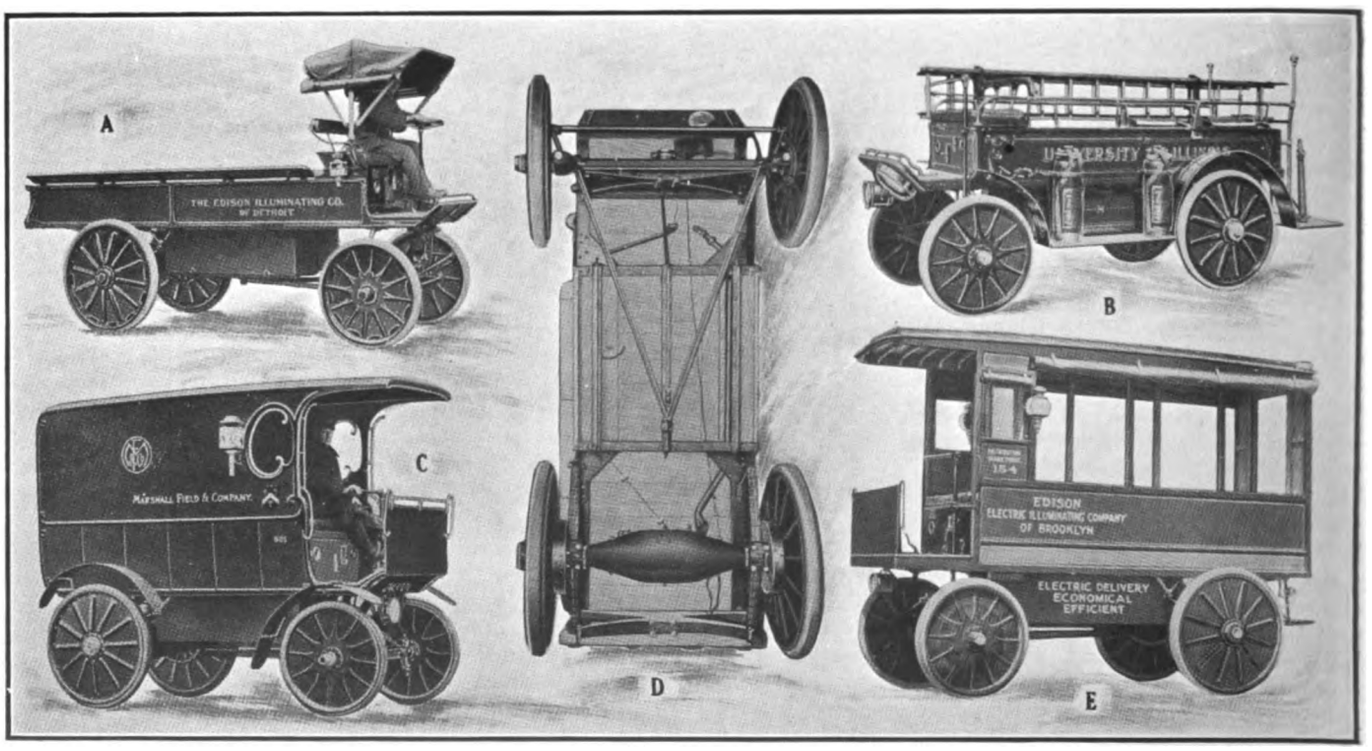

Fig. 2—Depicting Different Types of Bodies Fitted to Walker Balanced Drive Chassis: A, Flare Board Express; B, Combination Hose and Chemical Wagon; C, Panel Delivery; D, Showing Simplicity of Chassis Construction; E, Screen Body.

Digitized by Google

Four speeds forward and one reverse are provided, all controlled by the left hand, while steering is by wheel or lever with driver at the left. Two pedals are employed, one for the brakes, the other controlling the reverse, which is operated through the controller. Option is given in the matter of steering, a hinged horizontal hand lever or usual wheel being listed.

An ampere-hour meter is fitted to the dash in plain sight of the operator who may tell at a glance how much current has been consumed, this enabling the driver to operate in the most economical manner. It is claimed that the Walker drive is productive of 20 per cent. greater battery mileage, as all friction practically is eliminated. Regarding the mileage it is claimed that the minimum is 40 and maximum 80, according to the equipment.

The Walker vehicle is manufactured in normal load capacities ranging from 750 pounds to 2.5 tons, and the maximum speed varies from eight to 15 miles an hour. The battery, body, loading space and wheelbase are optional to suit the requirement of the purchaser.

★

In his address before the members of the Electrical Vehicle Association of New York City, recently, Stephen G. Thompson brought out some pertinent facts regarding the influence of the central power station on the use of electric commercial vehicles. In discussing the subject, "Is Central Station Activity in the Electric Vehicle Justified?" his general conclusions were that it is and that the electric is entering an increased field in commercial utility.

"It is estimated that 20,000 commercial machines are now in operation, and that within a year this number will be increased to 45,000 and in 1915, 200,000 will be in service, representing an investment of some $500,000,000," said Mr. Thompson. "The number of electric commercial cars is at present estimated to be 5000 of which 40 per cent. is employed in some 40 installations. This condition presents a new phase of the electric vehicle situation, and indicates a tendency on the part of the manufacturers to concentrate their efforts on a few customers and in the larger cities, thereby neglecting the less thickly populated territories.

"By cultivating this field the gasoline commercial car makers have been able in the past few years to market 200 per cent. more machines than have the manufacturers of electrics since their first entry into the market, and have emphasized the popular belief that the electric automobile is fundamentally for use in the larger cities alone.

"Of course, one may argue that in consideration of the number of gasoline vehicle makers, who outnumber the active electric commercial manufacturers in a ratio approximately 30 to one, the percentage of gasoline machines in excess of electrics is no indication that the makers of the latter type have been remiss in their efforts. However, the truth must be recognized that it is due more to the energy of the salesmen and agents of the internal combustion motor car than to any superiority of the machines themselves, that in a few years this type of automobile should dominate the market.

"If there be any truth in the oft reiterated statement that the electric will represent 65 per cent. of the total number of commercial vehicles employed at the end of 1915, instead of 50,000 electrics and 150,000 gasoline cars, based upon the present ratio, there should be 130,000 electrics and 70,000 gasoline; and it is this fact alone that justifies the central station in actively promoting the introduction of electric vehicles. There is no especially good reason why cities of 50,000 inhabitants or more should not present a fertile field for the sale of the electric in competition with gasoline cars, in that such communities represent the hub of a business area whose road transportation is confined principally within the city limits, while the bulk of suburban delivery is well within the economic zone of operation of an electrically driven machine.

"That the central stations are fully alive to the situation is evidenced by their present activity, which needs but the equivalent co-operation on the part of the vehicle manufacturers to precipitate an unprecedented electric boom. Many of the obstacles which opposed the early introduction of electrics have been removed. Excessive charging rates are a thing of the past.

"While some manufacturers entertain the belief that the charging facilities should be supplied by the central station for each individual user, the contention might just as logically apply to the free installation of motors, fans, etc. It would appear more rational to assume that the sale of a vehicle should include all accessories required for its proper care and operation.

"That the central station co-operation is effectively increasing the number of electrics in operation is manifested by the reports of the manufacturers themselves, who testify to an unprecedented demand for this type of machine, and that there is every indication that the central stations have more than performed their duty in nursing the electric vehicle industry to a state of healthful development.

"In Boston, New York City, Cleveland, Chicago, Detroit, Indianapolis, St. Louis, and many other localities, the increase in the number of electric vehicles has been quite marked; in some instances reaching 300 per cent. The aggregate increase is sufficient to warrant the belief that continued co-operation will produce a demand for electric machines far beyond the capacity of the present manufacturing facilities, and justify the prophecy that the time is not far distant when the general use of the electric vehicle may be expected to tax to the limit the existing central station installations."

★

Crowley, Milner & Co., a large department store of Detroit, and Toledo, O., has adopted the electric vehicle, having placed an order with the Anderson Electric Car Company, Detroit, for five Detroit electric trucks. Three of the fleet will have a carrying capacity of 1000 pounds and will be equipped with special delivery bodies. The remaining automobiles will be of the 1.5-ton type, fitted with furniture bodies with carrying space 13 feet long and six wide. Crowley, Milner & Co., made a careful and thorough investigation of the capabilities and possible service to be secured from various types of cars and decided upon the electric after it had demonstrated successfully its ability to make runs to Grosse Point, Wayne and other suburbs, 12 to 15 miles distant from the heart of the city.

★

The Springfield, Mass., fire department is to have another electrically propelled ladder truck similar to the one stationed at the Court street headquarters, this step having been decided upon by the fire commissioners. The new apparatus will cost about $10,000, it is stated, and will be installed in the new addition built recently to the Pine street station, affording better protection to that district, which has heretofore relied upon the horse drawn equipment. The new machine will be of the Couple-Gear storage battery type, made by the Couple-Gear Freight-Wheel Company, Grand Rapids, Mich.

★

The Edison Electric Illuminating Company, Boston, is planning one of the largest garages of the country for housing electric vehicles. It will be located on Commonwealth avenue, as a part of a large service plant.

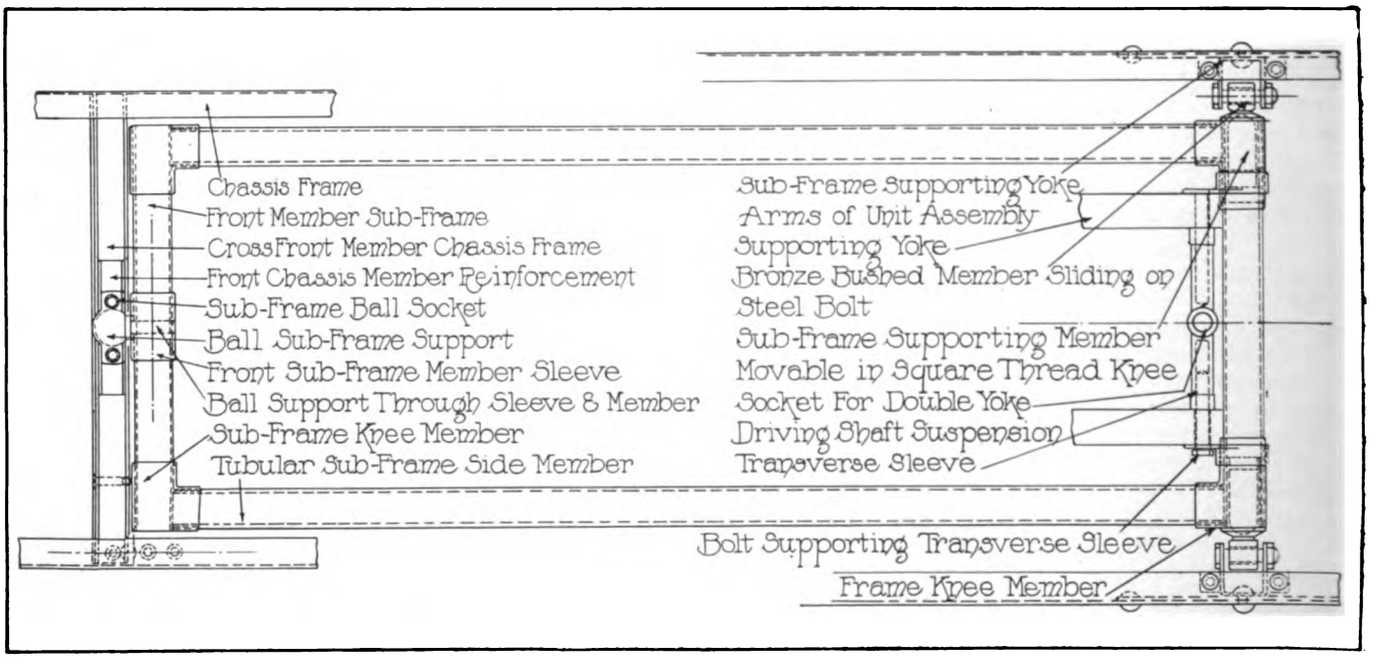
FOX SYSTEM OF POWER PLANT SUSPENSION.

Unit Motor Clutch and Transmission Assembly Protected from Chassis Frame Distortion, and Rear Axle and Shaft So Designed as to Be Relieved of Driving Stresses and Road Shocks.



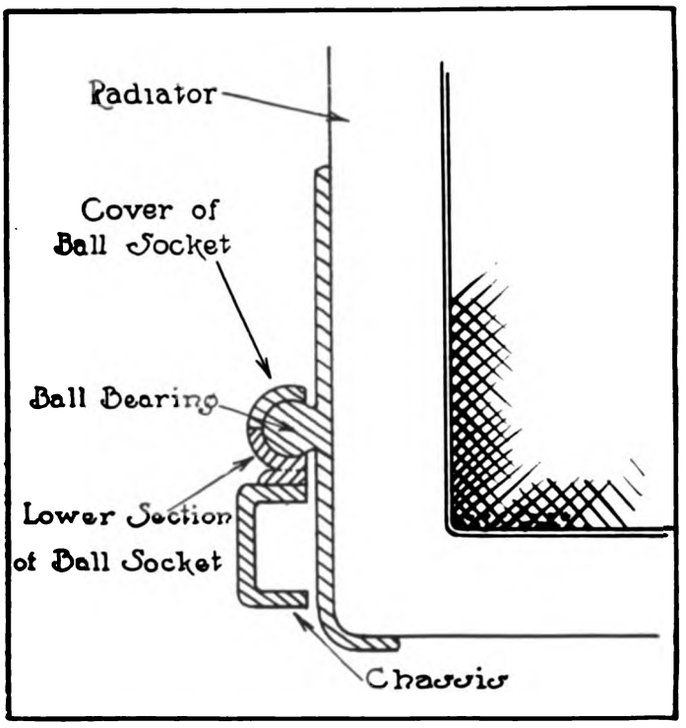
By Joseph P. Fox.

WHILE a motor vehicle chassis may appear to be a perfectly solid assembly while at rest so far as the unity of its members is concerned, when in motion it is subjected to stresses proportionate to its velocity, the load carried and the condition of the surfaces over which it is driven. These stresses are resultant from the shocks primarily communicated through the tires and wheels, axles, springs and frame. As the wheels may move or rest in a different plane the influence from each wheel may be more or less, unitedly or differently directed. The result is that the chassis frame is constantly subjected to twisting or distorting strains, which may be multiplied rapidly by the speed and road surfacing.

It is not practical to resist these stresses by heavier construction. It is essential to have light weight for many reasons. These facts have been long understood by engineers and manufacturers, who have sought to minimize the stresses by methods more or less productive of results. One design to receive material consideration has been the suspension of the power plant from three points, the purpose being to minimize the effect of the frame distortion which in turn is communicated to the engine case, the bearings and the shafts of the motor. Practical experience and theory have established the necessity of every moving part being in its precise relation to prevent the loss of power through excess motion or cramping of the mechanism. It is apparent that a very slight variation at a given point may be multiplied many times at another.

Then if this frame distortion cannot be prevented it must be compensated so far as possible. Three point suspension as applied by designers has many forms. It having been accepted as an engineering principle it has been employed to lessen the strains upon the motor or transmission cases, the bearings, gears and shafts, but as adapted by many the results have not been satisfactory. This has been due to the rigid installation of the motor or transmission in the chassis frame. Careful consideration of the proposition must establish conclusively that there can be little difference in results experienced from either three or four point suspension if the points for suspension are broad and firmly secured to the chassis frame.

Supporting arms of sufficient strength to carry the weight would undoubtedly strain or distort the engine case if immovably fixed. Then to obtain the precise result desired the means of suspension must not be rigidly fastened, but must be so designed as to maintain a perfect relation of members no matter what the influence of operation upon the chassis. That is to say, the mechanism to be preserved from the strains and stresses should have such movement as will compensate for the distortions or twists of the chassis frame. To accomplish this many constructions have been adopted, some by leading manufacturers.



Plan View of the Tubular Sub-Frame Carried by Ball and Socket Bearing at the Front and by Sliding Side Supports, Designed for the Fox Public Service Cab.

Daimler Truck Suspension.

An example is the latest Daimler truck, which has not only three point suspension for the motor, but for the transmission case as well. Both engine and transmission case have as one suspension point a large ball and socket, that for the motor being at the front of the case and for the transmission at the rear. Both motor and transmission cases have two swivelled bearings at the other ends. These swivelled suspension bearings are rigidly fixed, the purpose being to eliminate the twisting movement of the side members of the chassis upon the engine and transmission casings by the turning of the ball bearings in their

Digitized by Google

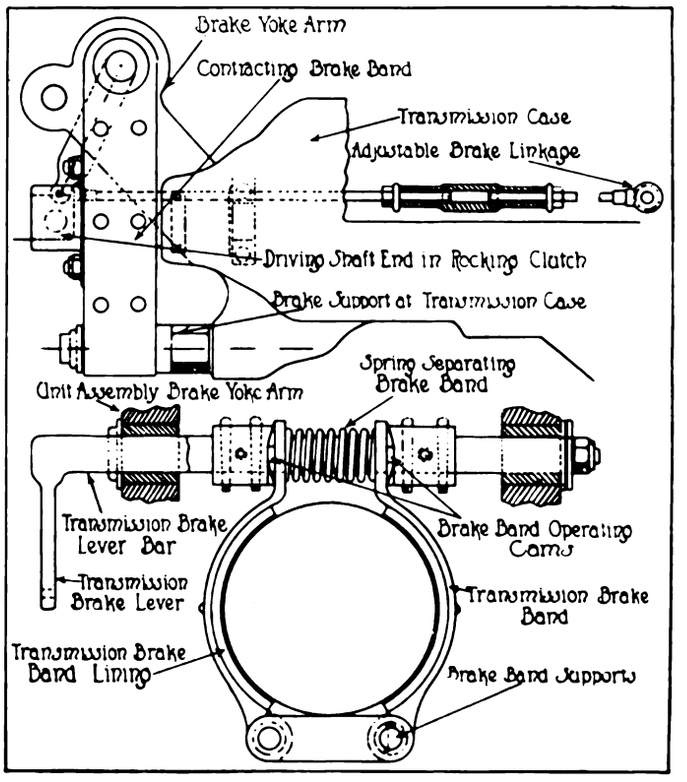
sockets. The intention is to compensate for the rocking motion of the frame. While this construction will no doubt afford relief from some of the strains of the flat, sinking

The Ball and Socket Mount for the Radiator That Eliminates All Twisting Strain.

movement of the chassis, it would appear that the peculiar assembly of the suspension points, as well as their rigidity against any bending motion of the frame, would be ineffective to protect the power plant against twisting strains.

There are many different forms of three point suspension, or at least applications of the principle. Some of the manufacturers who have adopted it have not redesigned their chassis, but have designed a form that may appear to be best suited to meet the requirements in the cars they build. The construction of many power plants is not such as to make possible the use of a true three point suspension and such vehicles may have the name but not the quality the term implies.

Value of Three Point Support.



The writer is of the opinion that there is no feature of car design paramount to three point suspension, and believes that the results obtainable are well worth the expense and trouble of reconstruction. But better still would be the designing and building of a power plant having all advantages of an actual or ideal three point suspension. This means that the power plant should be of the unit type in which the motor, clutch, transmission and gear shifting levers are assembled in one casing, this assembly being suspended in the frame from three points. The assembly should be so constructed as to rock or glide in a manner that will protect it, even on the worst roads, from all bending or twisting strains of the frame. With such construction the main shafts of the motor and transmission are sure always to be in line, thus dispensing with the usual universal joint between the two shafts and relieving the shaft bearings of all undue strains. When the engine and transmission are each suspended independent of the other in the frame of the car, even though each has a three point suspension, it is necessary to use a universal joint between them, so that in reality there is six, instead of three, point installation. The universal joint between the motor and the transmission at best but partly compensates for the influences of the twisting frame. The shafts are not in true line when the frame is twisted and the universal joint is expected to prevent shafts springing and excessive wearing of bearings. Universal joints cause friction and loss of power, are often noisy, require care and attention, and, worst of all, because of irregular transmission of power, cause shocks that affect the shafts and bearings, which theoretically ought to be free from friction. For the reasons stated the writer is of the opinion that the entire power plant should be suspended on three, not six, points. These conclusions were the reason for the design of the motor, clutch and transmission as shown in the description of the Fox cab.

Unit Power Plant Necessary.

This design has been worked out to have construction that will not be susceptible to the stresses upon the chassis, will maintain alignment of shafts and bearings, and compensate for any force that will create friction and result in lost power. To secure these results it has been found most practicable to use a tubular sub-frame, the plan view of which is shown herewith. This has been shaped to carry the full assembly and relieve it of practically all stresses. This frame carries the entire power plant, which is supported at either side by a wide flange or web extending from the front end to a point about the centre of the clutch housing. Besides firmly anchoring the plant this flange so strengthens it that it cannot be distorted by the greatest strain or shock it may be subjected to.

Sub-Frame in Fox Design.

By reference to the illustration the form of the sub-frame is shown, and into this frame is seated the engine, clutch and transmission assembly. The frame is of suitable tubing. The power plant is bolted to the sub-frame. The rear end of the plant is carried on the arms of a yoke supported by a bar which is parallel to the rear member of the

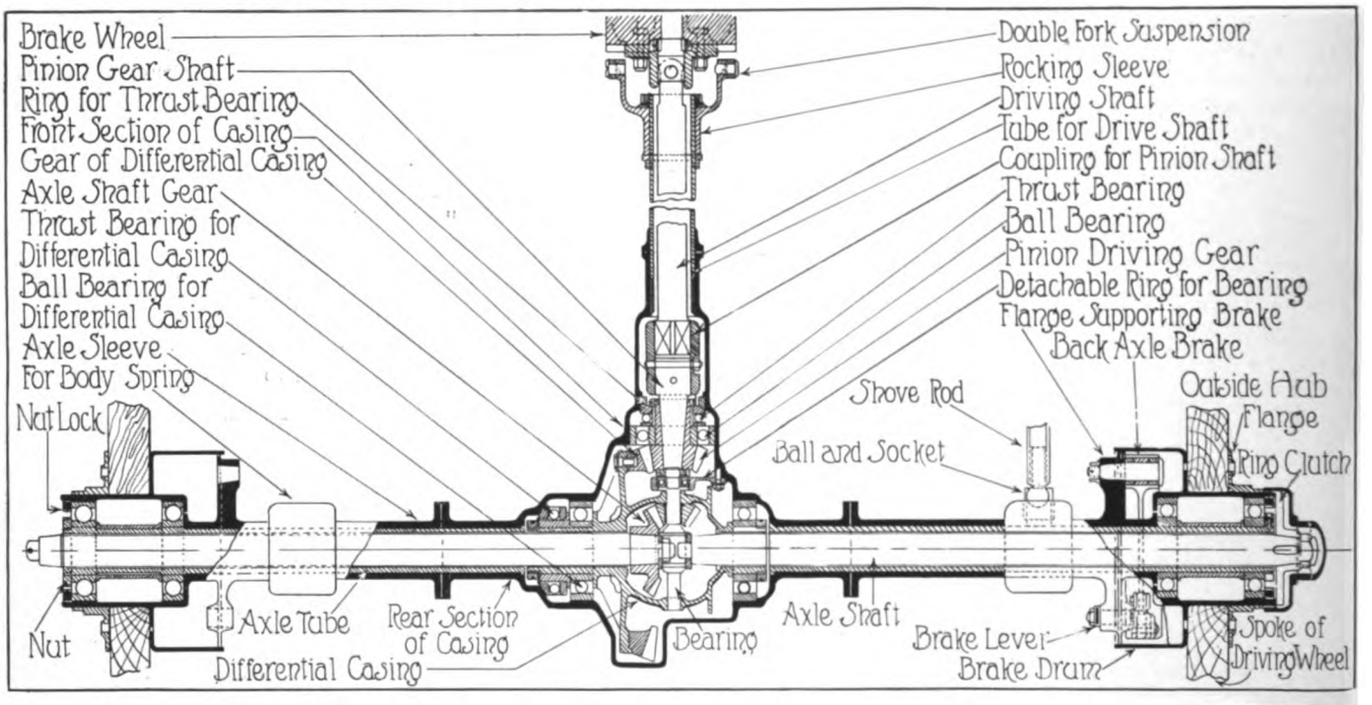
Plan of Construction of the Transmission Service Brake and Its Supports.

sub-frame. The side flange serves as a drip pan and protects the motor from water, mud, dust and road accumulation, quite as well as a sheet of metal.

Digitized by Google

A sleeve is fitted to the centre of the front sub-frame member which is the support for a ball shaped bearing. This bearing is supported by a ball socket centred on the top of the front member of the chassis frame. The upper half of the socket is fastened to the lower by bolts and nuts. By removing the nuts and the upper half of the socket the forward end of the sub-frame may be raised, the rear supports being designed to permit this movement.

The rear supporting members E are screwed easily into the knees at the ends of the rear member of the sub-frame by square cut threads, which permit an easy rocking movement in the event of the chassis frame twisting, or should the forward end of the power plant and sub-frame be lifted. The outer ends of the supporting members are bored and bushed with bronze and these bushings are secured by bolts to yokes having flanges riveted to the upper and lower sides of the channel section chassis frame side members. These supporting members have a longitudinal movement on the bolts. Obviously the movement of the chassis frame is least in the centre and greatest at the ends. Should there be any lifting or twisting motion of the frame sides the sub-frame will rock on the ball and socket bearing. Should there be forward or backward motion the sub-frame side supports will slide correspondingly on the supporting bolts. There will be no stress upon the shafts or bearings.



Time Economy a Large Factor.

This form of suspension minimizes the labor of assembling a power plant, a matter of decided importance with cab owners, for spare power plants may be used and the chassis kept in operation in the event of engine defect or failure. With proper facilities and skilled workers the plant may be removed and replaced by another in an hour. Under the conditions usually existing today such a change would require from one to two days and perhaps longer. As may be noted, it is only necessary to remove the upper half of the ball and socket support to free the sub-frame so that it may be raised.

As the motor is firm in the sub-frame, and the sub-frame has such suspension at the rear that it may move slightly in a longitudinal direction, and it may rock or swing at the forward bearing, it will be seen that it is free from all twisting strain. This relieves the motor shafts and bearings from all stresses and, strengthened by the supporting web, the engine case cannot sag. The section of the motor assembly back of the crankcase, containing the flywheel and the transmission, is also rigidly held by this construction, and yet any movement of the shafts is perfectly compensated. By making further reference to the sketch, it will be seen that the rear sub-frame member carries near the outer ends two firmly fixed sleeves, to which are fitted lugs. These lugs are bored and through them, paralleling the rear sub-frame member, is a transverse bar that may turn on the bolts that retain and support it in the sub-frame. From this bar is suspended a yoke that may move backward or forward by the swing of the bar or from side to side, this in effect being a universal joint. Into this yoke is bolted the yoke of the tubular driving shaft housing, affording a substantial but flexible suspension.

Transmission Brake Support.

The rear end of the motor assembly case carries arms for the suspension of the transmission brake band, which is the contracting type, the brake lever and the supporting rod. By following the driving system through from the engine crankshaft it will be seen that the crankshaft rear extension carries the flywheel and the movable clutch member. The cone of the clutch is on a sleeve that engages with a clutching member carried on the end of the driving shaft of the transmission. This shaft is coupled to the continuation of the transmission driving shaft. On this continuation of the transmission driving shaft is mounted the transmission brake wheel or drum. Attached to the brake wheel is a rocking clutch, so-called, in which the forward end of the driving shaft is socketed. This rocking clutch permits movement of shaft in all directions without causing a strain. This driving shaft is carried in its tubular housing held by the yoke suspended from the rear of the sub-frame. As the shaft is free to move longitudinally in a squared sleeve at the rear end there is a slight telescoping movement which compensates for the motion of the rear axle. It will be seen that there is no strain upon the shaft as the chassis frame rises or falls upon the springs,

Plan View of the Driving Shaft and Rear Axle Assembly for the Fox Cab, This Showing the Reinforcement of the Sectional Axle Housing, the Strong Wheel Bearings, and the Means for Compensating Road Shock Stresses.

Digitized by Google

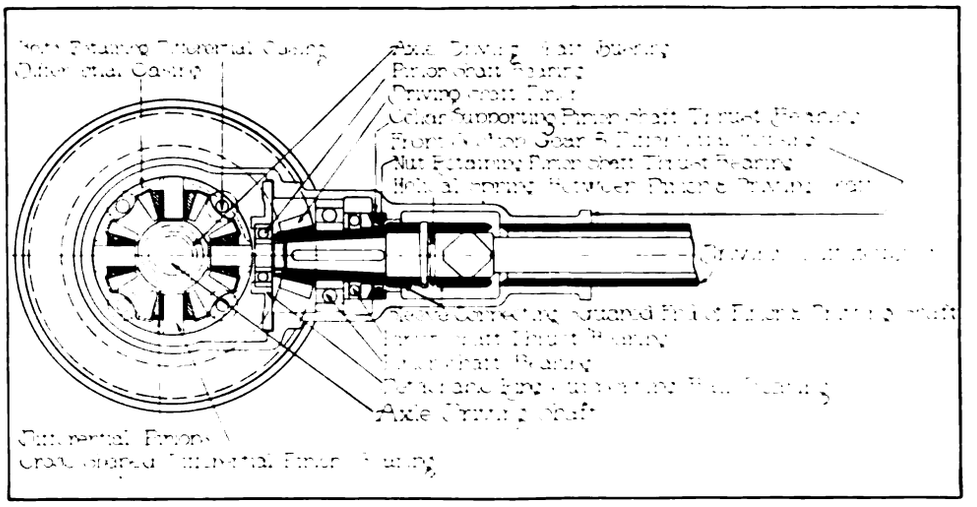
or when there is a twist of the frame. There is no thrust upon the shafts or the bearings at any time.

Considering the construction it will be seen that while the motor is held in the sub-frame and protected by this suspension from any strains or stresses, this same sub-frame carries the forward end of the driving shaft housing and, as there is allowance for movement of the chassis frame, the sub-frame and the shafts, there can be none of the stresses and but a small degree of wear as compared with a design in which all of these elements are rigid. It will be apparent that with imperfect suspension but little movement may cause bearings to be jammed, shafts to be bound so as to cause excessive friction, gears to be thrown from the precise relation necessary for efficiency, and other conditions precipitated that will cause lost power and destructive wear.

Driving System Protected.

Examination of the entire driving mechanism of the cab will demonstrate that the elimination of shocks and stresses has been carefully studied. Beginning with the clutch and concluding with the contact of the traction wheels upon the road it will be understood that there has been endeavor to have an elastic construction that will have every desirable quality. Considerable emphasis has been made upon the three point suspension of the sub-frame and the power plant, but it is also apparent that the driving shaft and the rear axle construction are given material protection through the yoked connection of the forward end of the driving shaft housing, which will yield slightly to compensate any straining movement, and the freedom of the semi-elliptic springs to move and cushion the road shocks. With the full floating type rear axle the axle housing sustains all the weight and the axle shafts and differential are protected against every influence so far as this may be done.

In explanation of the driving system it may be pointed out that the engine crankshaft, carried on five ball bearings, is always free from stresses. On the rear end of the crankshaft is carried the flywheel and this is very close to the rear main bearing to prevent vibration. The shaft is tapered and the flywheel is keyed on it and further retained by a locking nut held by a pin and a locking spring. Into the hollow end of the crankshaft is screwed a shaft extension or spigot which is also retained by the pin and locking spring. Surrounding the spigot is the clutch spring which is compressed and normally holds the clutch engaged by expansion. Back of the spring is a collar and then a ball bearing, and next is the adjustable collar by which the clutch spring tension is established. The flywheel is with the face divided, the inner face of the rear ring or section of the wheel being machined to the same angle as the clutching member. The flywheel is of cast iron, the clutch cone member of aluminum.



Flywheel and Clutch Assembly.

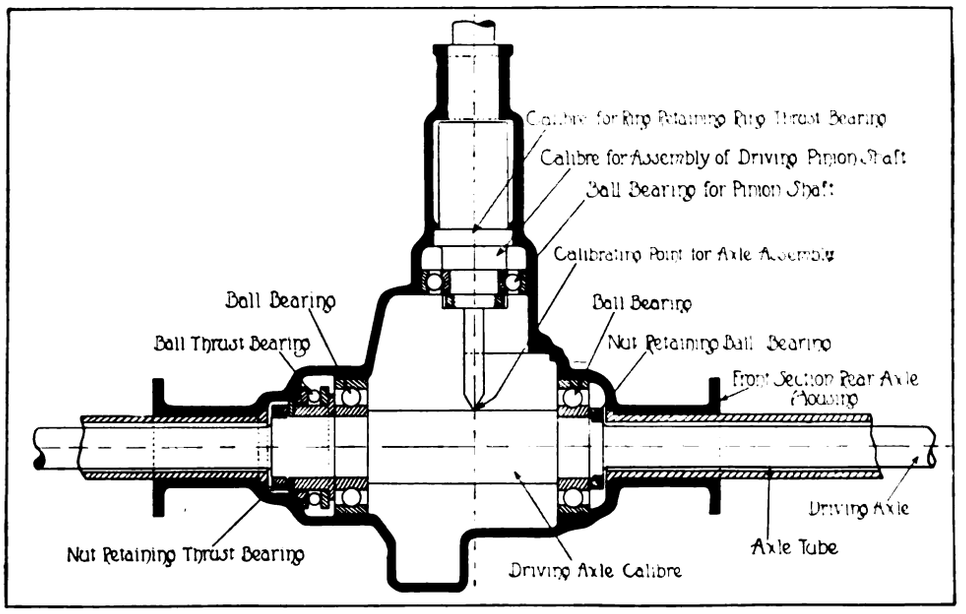
The flywheel sections are held by bolts so that normally the clutch cone contacts with the internal angular face. The clutch cone is mounted on a sleeve carried on the spigot on which it has a longitudinal movement. On the cone sleeve is a ball bearing for the fork of the clutch lever. This bearing is assembled with a member that carries the three pins of the shaft clutch. As the clutch spring is compressed the clutch is disengaged, it sliding forward on the spigot. As the clutch pedal is released the spring throws the cone backward into contact with the bevelled inner surface of the flywheel. At the rear of the transmission case is the clutch uniting the transmission driving shaft sections, and back of this is the rocking clutch that is carried at the rear of the transmission brake drum, in which is mounted the forward end of the main driving shaft.

This internal cone clutch is designed to be adjusted with a minimum of labor. It is wholly encased with the flywheel in an oil and dust tight compartment and it is free from the usual influences for wear. It is perfectly lubricated and it cannot be subject to the usual causes of clutch trouble. The clutch design is conducive to a minimizing of the oscillatory movement of the crankshaft of the motor and engagement can be made without perceptible jar or jolt.

Clutch Removal Quickly Done.

The clutch may be removed from the case by removing the upper case section, the operation being comparatively easy. By removing the bolts retaining the flywheel sections, the locking spring, the pin and the locking nut and the coupling members of the clutch, and then holding the clutch cone and the spigot in relation by means of a special wrench, the spigot may be backed out of its socket in the end of the crankshaft. This being done the clutch cone, spigot, and the detachable half of the flywheel face may be lifted from the case. This form of construction simplifies any work that may be necessary on the clutch. Every member may be removed and cone refaced or any part restored without affecting the other groups of the assembly. This is a condition that may be well appreciated by those who have to do with automobile maintenance. The lifting of the footboards and the removal of the upper section of the clutch case gives fullest access for any repair, while there is a large handhole for inspection.

Sectional View of the Differential Assembly, Illustrating the Driving and Pinion Shafts Engaging with a Sleeve in Which Either Has Telescopic Action.



There is conventional construction of the transmission gearset, which has been briefly described. This has the four forward ratios and reverse and the countershaft parallels the main shaft at the side. To secure rigidity of the assembly this end of the case is strengthened by bridging and the overlap of the section joints of the case, which, it will be understood by those who have noted this design, are large and strong. The transmission case is in three parts, the lower, which carries the shafts, gears and bearings, the upper, and the inspection hole cover. That the lubricant with which the case is filled may not enter into the flywheel and the clutch section of the case there is a stuffing box in front of the forward bearing, and a drain from the bearing

Digitized by Google

carries all excess grease or oil back into the base of the transmission case.

No Strains from Driving System.

This section of the case is subjected to no driving strains whatever, for the flange supporting the power plant assembly extends from the front to a point midway of the clutch compartment. The clutch lever is mounted at the base of the case and there is no transverse strain from its movement. The transmission brake is similarly operated, but the brake wheel is carried on the shaft directly in front of the double yoke supporting the forward end of the main driving shaft, and the rocking clutch at the rear of this wheel prevents any stress whatever upon the shafts. The arms at the extreme rear end of the assembly carry the brake band for the transmission or service brake. This brake band is of the contracting type with the ends carried on a bar. It is jointed at the centre below the brake wheel and is lined with soft iron. The ends of the brake band are normally kept separated by a spring. At either side of the brake band ends are collars having cams contacting with the band, so that when the supporting bar is turned slightly the cams contact the band tightly about the wheel affording a very efficient brake.

Section View of the Differential Housing, Showing the Method Employed for Calibrating the Gear Assembly to Secure Accuracy and Interchangeability.

Considering this construction for a moment it will be understood that there is no connection of the power plant through brake or clutch levers with the chassis frame. The control levers are mounted on the motor assembly and with the left side drive the driver has right hand levers which are in every way independent of the usual connections. Any twisting stress is avoided and the moving parts are free from influences that might cause excessive wear or friction, while accessibility is always pre-eminent. In fact this characteristic is extended to the cooling system. The radiator is regarded as being especially susceptible to the chassis frame stresses and to protect this the frame in which it is mounted is supported by two ball and socket bearings so that any movement is compensated and the radiator is never strained. The radiator may move independently of the motor because of the flexible connection of the water manifolds, and there is a swivelled rod extending from the dash to the radiator frame to maintain its relation without rigidity.

Three Point Rear Axle Suspension.

The rear construction, comprising the propeller shaft, differential, rear axle, driving shafts, wheels and brakes, has been designed with especial care to meet all of the conditions to which it will be subjected in the usual service of a public cab. There is no part of the mechanism of a chassis on which more time and money is expended than the driving wheels and shafts and it is essential that these be not only enduring but of such form that they can be easily maintained. That the rear axle is oftentimes so expensive is not an occasion for wonder when the heavy work it is constantly subjected to, the design, material and workmanship are considered. Other groups of the assembly are protected by three point suspension, elastic springs and shock absorbers from strains, twists and shocks, but the rear axle is carried directly on the rear wheels and must bear every stress from contact with road obstruction. The greater the speed the more severe the impact. There is absolutely no protection except in reduction of movement, which is precisely what is not wanted by those who desire cab service.

Every detail of design, construction and assembly, as well as the selection of parts and material, must be given the greatest care. The purpose is to obtain what will in every way endure, have ample margin of strength and yet be as light as possible. With only the tires to absorb the shocks it is evident that the one object is to escape every influence for deterioration and weakness. For these reasons I am not favorable to incorporating the speed-changing gear with the rear axle assembly. Not only would this increase the unsprung weight but would also subject this mechanism to greater wear. Besides this the weight is added to by the rods and levers necessary for operation, which must also wear, and there is always more noise as the service of the car is extended.

Advantages of This Design.

The rear axle construction may be likened, indeed, it may be classified, with three point suspension in that two points are supported by the wheels, while the connection of the forward end of the driving shaft may be regarded as the third. It is evident that every advantage should be gained from this so that an easy, rocking or swinging movement of the rear axle should be made possible by the construction and suspension of the shaft. This movement, once provided for, should not be restrained by other parts more than is necessary and consistent with the proper support of the vehicle.

It is necessary to assemble in such a construction, and within the centre of the rear axle, the differential gears, driving and axle gears, the shafts and bearings. To obtain good results the gears must be in perfect mesh and the shafts in perfect line if a quiet, frictionless and economical transmission of power is to be realized.

To accomplish this it is necessary to suspend the centre of the rear axle, where there is always a heavy strain, so as to protect the gears, shafts and bearings from the weight of the vehicle, as well as the other destructive influences. Of these the driving strain of the shaft pinion and the use of the brakes are by no means least. These purposes are best served by the use of a full floating axle, which has been adopted in the design of this cab.

Digitized by Google

Full Floating Rear Axle Drive.

By reference to sketch it will be seen that the frame or axle casing carries the full weight of the rear of the car, thus allowing the axles to be assembled at full float. That is, in such manner that they will be only subjected to the turning strains necessary for the transmission of power to the driving wheels, but never to the bending strains which the axles are required to sustain when the driving wheels are attached to their ends. With the semi-floating type the shocks received by the driving wheels are transmitted to the differential drive shaft, gears and bearings, naturally affecting all of them to a greater or less extent. With excessive wear comes greater friction, noise and eventually destruction. A bent axle shaft is not an unusual condition experienced with vehicles of such axle construction.

By further reference to the drawing it will be noted that the housing for the drive shaft is suspended from a point directly above the rocking clutch incorporated with the transmission brake by a double yoke and sleeve that permits the axle housing a free rocking movement in all directions. This suspension point is the transverse bar that parallels the rear sub-frame member. If there be any change of the rear axle with relation to the line of the engine and transmission shafts, the shaft housing always is free and clear of any strains that might bind bearings or gears or cause undue friction. The rocking clutch and the double yoke establishes the entire driving construction back of them to be as another group, practically separate and apart. This design largely eliminates the leverage pressure of the driving shaft and the heavy reactionary pressure on this shaft when the brake is applied. It relieves the shaft from all strains save those necessary for the transmission of power. It will be noted that the driving shaft is really in two sections, the shaft itself and the pinion shaft to which the driving pinion is fixed. The rear end of the driving shaft and the forward end of the pinion shaft are squared and these ends are fitted into a sleeve in which either may move longitudinally, a spring separating them slightly and maintaining a relation so that there is no thrust whatever upon the bevel gear, the pinion, the rocking shaft, transmission brake wheel or the transmission shaft extension. The forward end of the driving shaft in the rocking clutch has a ball head so that there can be no strain upon the bushings. The relation of the rear axle and the frame are maintained by two radius rods or shove bars having ball and socket connections at the axle which do not restrain the movement of the axle in any other direction. These rods relieve the springs from the strains of propelling the car and prevent a swinging motion of the body on rough roads.

Axle Housing in Four Sections.

The rear axle housing is in four sections, these being the central section which contains the differential and the bevel gear, divided vertically on a line paralleling the axle, and the two end members. Referring to sketch it will be noted that the axle sections are bolted together by flanges well outside the centre line of the differential. The ends of the end sections of the housing carry the heavy flanges on which are installed the shoes and the rods actuating the internal expanding brake. Through the axle housing from either end to the differential bearings extend heavy steel tubes which reinforce the construction and project beyond the flanges at the housing ends. On the ends of this tubing are the double ball bearings on which the wheels are mounted. The design is such that the axle housing joints will sustain many times the weight or strain they have to bear without being deflected from the true lines.

The differential assembly consists of four pinions and two gears, the whole carrying the bevel or driving gear of the rear axle. The driving gear is at the left side. At this side is both a ball thrust and a ball bearing, and at the right is a ball bearing, on which the differential assembly revolves. The axle driving shafts at the outer ends are fitted with clutch plates which mesh with clutch rings fixed at the outside of the hubs of the rear wheels so that the wheels are constantly retained. The leverage pressure upon the driving and pinion shafts is eliminated by the two ball bearings to be noted, the one in front of the pinion gear on a detachable ring and the other just behind this gear, supported by the driving shaft extension of the axle casing.

Ball Bearings for Moving Members.

Throughout the rear axle construction five ball bearings are used and there are two ball bearings in each of the wheel hubs, set well apart to secure steadiness and smoothness of wheel movement. The shafts and gears of the driving system are made from chrome nickel steel, this insuring the greatest strength and lightness. The driving shaft is suspended in the chassis so that when the vehicle is loaded the drive is practically in a straight line, this permitting the utilization of nearly all the power developed by the motor. The driving and axle shafts and the differential are operated in an oil bath, which affords the fullest quality of lubricity.

It is well known that with the full floating type of axle construction the application of a balanced brake does not load or strain the shafts and gears. In fact such brake gives the best service and is the most economical in its wear upon the transmission system. It is for this reason that I have designed the wheel brake for constant service, to be operated by the pedal, and the emergency brake on the transmission to be actuated by the hand lever. The importance of this assembly is not to be under-estimated, for the pedal is the quickest to operate, is the most convenient and will be used by the driver in practically every case in preference to the hand lever.

It will be seen by observation of the details described that the power plant and driving mechanism of the cab have been designed with the purpose to escape so far as this is possible all conditions that may cause unnecessary wear and deterioration. The assemblies have been made oil tight and dust proof and protected against all accumulations of abrasive substances. The flexibility of the constructions throughout has been sought with a view to insure against every condition that might cause wear The lubrication has been studied with a knowledge of the need of a sufficient supply at all times. The utilization of the power has been made with the smallest motor that would serve all requirements. The materials chosen have been the best and the workmanship necessary in the production of the parts is to secure standardization and interchangeability. The mechanism may be inspected, adjusted and restored with the least labor and consequently little loss of time and service. The cab is intended for long and continuous work that may be required under average conditions, and because of undoubted economy from the viewpoint of the operating company and the satisfaction to be obtained by the patrons, the design appears to the writer to have much to recommend it.

TURNTABLE MEETS WITH FAVOR.

Turntables are invaluable in garages, and the Portland Garage Company, Portland, Me., which produces these devices is the recipient of many testimonials from leading garages and factory branches praising its appliance. The company constructed a special table for a manufacturer who exhibited at the New York and other shows.

TO TEST SAMPSON ARMY WAGON.

Although it has been stated that the government intends to replace the army mule with the automobile, nothing has been done as yet in an official nature toward buying or ordering in large quantities.

The purchasing thus far has been confined to a few cars, and these have been ordered by the quartermaster's department. One of these contracts was placed with the Alden Sampson Manufacturing Company, Detroit, a constituent of the United States Motor Company, New York City, and the machine which is depicted in the accompanying illustration, was built under special requirements and specifications furnished by the government.

From the standpoint of army practise in field equipment, this truck is not unusual although its features are interesting in that they differ from what is standard practise with makers of commercial vehicles. For example, the wheels of the Sampson are 42 inches in diameter, both front and rear, this size being necessary to give the clearance required in cross country work.

As the mule drawn equipment has to ford streams, travel through open fields and run over stones, etc., the government requires that the successor to the old method shall be equipped to do this work. To haul the car out of mud holes or places where traction cannot be secured, the wheels are constructed so that winch heads may be attached by means of simple hook bolts. The rope is fastened to some fixed object and a few turns taken around the winch heads. The slipping of the wheels winds the ropes, drawing the car from its position. The driving chains are enclosed in sheet metal casings, these serving to keep out the dirt and mud as well as distance and torque rods.

Sampson Army Power Wagon Constructed for Quartermaster's Department, Which Is Undergoing Trial in Texas.

The seat is built over the engine, a practise characteristic of the Sampson 3000-pound capacity wagon. The inside body dimensions are nine feet by 43 inches wide. It is equipped with flare boards on side and a tail gate of height equal to that of the side members. These are heavily reinforced with iron and chained. Conforming to army practise the carrying receptacle is fitted with removable bows and a canvas covering.

It is interesting to note that the government specifies a maximum speed of nine miles an hour. The normal speed of the motor is 1000 revolutions a minute and the engine is restricted by a governor. A specially low gear is fitted. Another notable feature is the tread. This is 60 inches which suggests that a wide range of service is anticipated. The wheelbase is 110 inches and the vehicle is designed to carry a load from 2500 to 3000 pounds.

The motor is a four-cycle, four-cylinder, water-cooled unit, having a four-inch bore and five-inch stroke. It is mounted on a pressed steel frame, 4.5 inches deep, and the flanges are tapered from four inches wide in the centre to two inches at the ends. The front axle is a standard forged I beam section steel member while the rear is 2.5 inches square with hubs having roller bearings. A multiple disc clutch and a three speed transmission is fitted, and a double set of brakes, these being of the internal expanding type and practically self wrapping in either direction. The automobile was sent to the Mexican border recently.

MOTOR TRUCK STANDARDIZATION.

At a recent meeting of the special committee appointed by the Society of Automobile Engineers to consider the course of action to pursue in furthering the work of standardizing mechanical transports it was decided that it was desirable to attempt to standardize the sizes and capacities of trucks from the purchaser's or user's standpoint, and afterwards to extend the work in the direction of aiding the manufacturers in standardizing design.

The next proceeding was to determine the specification of normal load and the overload of machines from one to five tons and it was generally decided to vote that each car should be capable of rendering normal or continuous service under its tonnage rating and have an overload capacity for temporary or emergency service of 25 per cent. of its normal tonnage capacity.

Next an attempt was made to determine the desirable speeds for various sizes and by a process of voting the following was arrived at: For one-ton trucks, 15 miles an hour; two-ton, 12; three-ton, 10; four-ton, nine; five-ton, eight. These determinations may be modified later, however.

Considerable discussion took place as to what the determining factors for capacity should be and it was agreed that the committee would take under consideration in this connection horsepower expressed in the dimensions and speed of the motor, as well as in draw bar pull of the truck in completed condition.

It was determined that the committee should write to the manufacturers of axles for both motor trucks and horse vehicles and enquire their present practise insofar as dimensions relate to load carrying capacity. It was also determined to secure the specifications of machines now manufactured and at a little later date request the recommendations of manufacturers as to what their judgment would be in the matter of critical specifications on various truck sizes insofar as they relate to axles and their essential elements.

This subject is one which has an interest for manufacturer and user alike, in that with proper standardization the purchaser will be able to judge better the respective merits of the machines offered for his inspection.

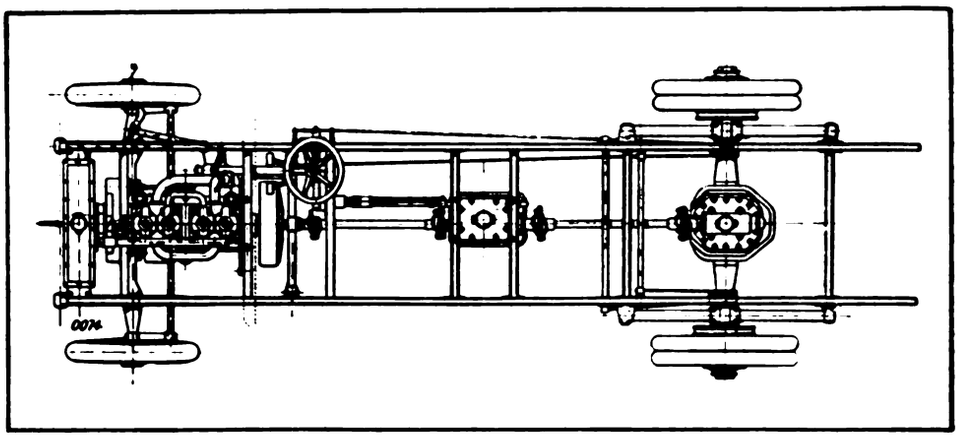
FOREIGN TRUCK NOTES OF INTEREST



KNIGHT ENGINE FOR DAIMLER TRUCKS.

While the Knight sleeve engine has been used with splendid success in a number of pleasure cars abroad and in this country, it has made little progress in the commercial vehicle field. The first models thus equipped are announced from the factory of the Daimler Company, Ltd., Coventry, England, these comprising: One-ton delivery wagon, two and three-ton trucks, 40 horsepower omnibus, five-ton truck and 100 horsepower agricultural tractor. In addition to the Knight engine these cars are fitted with the worm drive.

The motor in the one-ton vehicle has a bore of 90 mm and stroke of 110 mm, and is rated at 27 horsepower at 1200 revolutions. The cylinders are cast in pairs. Lubrication is by plunger pump, which delivers oil to troughs beneath the connecting rod big ends. Ignition is by Bosch high-tension magneto, as is true of all the models. A leather faced cone clutch is employed. The transmission is of the selective sliding gear type, giving three speeds forward and reverse.

The worm and worm wheel are carried inside a cast steel housing to which are attached the hollow forged flanged steel axle tubes. A large cover is fitted over the top, and this supports the worm and wheel as well as the differential gear. It is possible, by removing this cover, to take out the whole of the gearing.

Two sets of brakes are provided, both acting on the rear wheel drums. The frame is of ash, reinforced by nickel steel plates, and the cross members are of similar construction. The wheels are hollow steel castings, mounted on ball bearings.

General Arrangement of the New English Daimler Truck Chassis, Equipped with Knight Sleeve Valve Motor and Worm Drive.

The same description will apply to the two-ton model. The three and five-ton vehicles and omnibus are fitted with an engine of 40 horsepower, the bore being 110 mm and the stroke 150.

The tractor's motor has a bore and stroke of 150 mm, which is started by a three horsepower air-cooled engine, located on the footboard beside the driver. This auxiliary motor drives a belt attached to a pulley on the rear end of a shaft which runs forward to a small disc wheel, engaging with a groove on the flywheel of the main power plant. The worm, which is of ample proportions, is located directly over the axle, and the drive is taken from its cross shaft by means of pinions, which are located vertically over the final spur rings bolted to the road wheels, the latter being standardized at eight feet in diameter. It is claimed for this tractor that it can pull 14 to 21 disc plows, cutting a furrow up to eight inches in depth. Actual tests are said to have demonstrated that it can turn over 3.75 acres an hour on a gasoline consumption of 11 pints an acre.

STREET CLEANING IN PARIS.

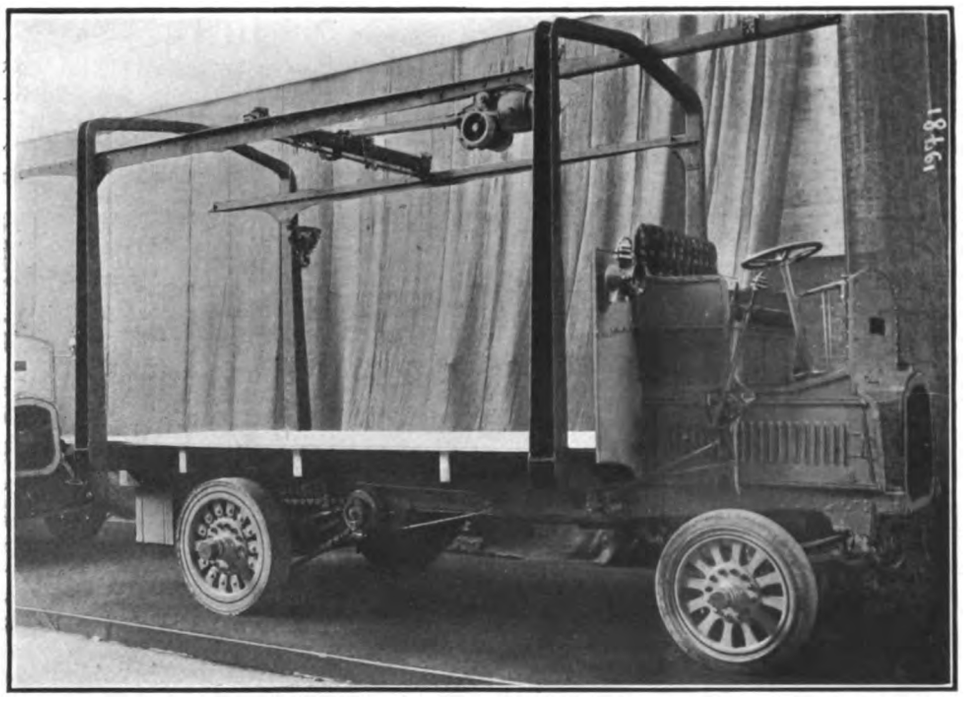
The municipality of Paris, France, is experimenting with four types of motor driven street cleaning machines. These include a straight sweeper, sweeper with spraying jet to prevent dust, combined sweeper and watering cart and watering carts with large capacity for washing streets.

The first named types are supplied by Louis Renault and Sautter-Harle & Co. The former maker utilizes the standard twin-cylinder motor of 80 mm bore and 120 mm stroke as employed on taxicabs. The Sautter-Harle machine is driven by an engine having 90 mm bore and 140 mm stroke. With the latter the brush is driven by means of side chains, operated from a countershaft engaging with a pinion within the differential housing. On being raised the brush is declutched automatically, and provision also is made for regulating its height as wear of the bristles takes place.

The sweeper and sprinkler is furnished by the De Dion-Bouton Company, and is distinctive by reason of the fact that the brush is located under the centre of the vehicle. The fan-shaped sprinkler is just ahead of the brush. The combined sweeper and watering cart is produced by the Laffly concern. A 77-gallon water tank permits the street to be thoroughly watered before the brush rolls over it. Still another combination vehicle is the front driven Latil, which is equipped to flush the street with water for washing immediately after the brush has passed over it. Two water pumps of low capacity are utilized for watering only, while a third with much larger capacity is used for washing.

POSSIBILITIES IN MALAY PENINSULA.

Good opportunities for establishing motor truck lines, possibly with a tractor and trailer combination, are said to be found in the Federated Malay States. One instance is cited in the vicinity of Kaula Lumpur, the centre of the planting country. The 30 miles of road between that town and Port Swettenham is in excellent condition and taps the fertile valley of the Klang. The present railway line is said to offer very unsatisfactory service, and the growth of the export business through Port Swettenham has been such as to compel the producers to seek some means of relief. Motor trucks would be able to cover the distance in a few hours.



The same thing holds true in Singapore, where the

Digitized by Google

transportation of goods from the wharves to the business houses is in the hands of two companies, one of which has begun the use of motor vehicles and with excellent success. Among the more recent ventures may be mentioned the establishment of a motor passenger and freight service between Kuching and several of the adjacent towns. A two-ton truck has been ordered from England, the promotor being Tan Boon Siew, manager of a local Chinese firm.

MODELS PRESENTED AT BRUSSELS SHOW.

Inasmuch as there has been a decidedly increased interest in commercial vehicles in Belgium, following important improvement in the highways subsequent to the international road congress of 1909, it is anticipated that this country will offer a splendid market for industrial transports during the coming year. The recent automobile and aerial craft exhibit in Brussels, demonstrated that local capital is taking advantage of the outlook, as no less than four new Belgian motor truck manufacturers were represented with vehicles of various capacities.

Delahaye Five-Ton Brewery Vehicle, Fitted with Electric Hoisting and Travelling Device Displayed at Recent Brussels Show.

Albert Bory of Brussels, regarded as the first commercial vehicle constructor in Belgium, presented a 3.5-ton chassis, which has been adopted by the Belgian army, and two light delivery wagons. Robinson & Co. of Antwerp showed a new electric vehicle, in which each front wheel is driven by a five horsepower motor. The Auto-Mixte Company of Liege displayed a tractor and trailer, comprising a six-wheeled train, in the rear compartment of which a flying machine was packed away as if ready for shipment. The Preudh'homme-Prion Works of Huy exhibited a six-ton truck, a duplicate of those ordered from this concern for the Russian government.

Among the more important exhibits of older firms was that of the Delahaye, which was represented by 3.5 and five-ton models. The first was of the subvention type, with 24 horsepower motor of 80 mm bore and 140 mm stroke. The five-ton vehicle was designed for brewer's use, although of course it might be employed similarly in other lines. The engine is rated at 32 horsepower, having a bore of 100 mm and stroke of 160 mm. The driving wheels are fitted with solid tires, in which steel studs are imbedded. The distinguishing feature is the electric hoisting and travelling gear, supplied with power from a small dynamo driven from the engine. The accompanying illustration brings out this feature.

SCOTLAND'S COMMERCIAL CAR EXHIBIT.

The annual show of the Scottish Automobile Club, which was held this year in Glasgow instead of Edinburgh, did not reveal any large number of new features, having in mind the display at the Olympia show earlier in the season. Some very splendid body designs were shown, particularly with respect to so-called municipal service wagons and ambulances. In the matter of construction, the worm drive appears to have been extended slightly.

Only one American car was seen, the White, made by the White Company, Cleveland, O. This was shown in the three and five-ton sizes. One other model is of special interest to Americans, inasmuch as it is made under license in this country. This is the Commer, which was shown by Commercial Cars, Ltd. It displayed the three and five-ton trucks, ambulance and two 'buses. One of the latter was fitted with a worm drive.

The Dennis concern, which supplies a large number of British cities with their fire apparatus, showed a new gasoline driven pumping engine, capable of throwing 500 gallons of water a minute. This company also displayed a three-ton vehicle fitted with a worm drive and other features characteristic of the Dennis make.

One of the most interesting exhibits was that of D. Stewart & Co., with the Stewart-Thornycroft steam vehicle rated at five tons. No change was noted in the boiler equipment, but the road wheels are now of the Reid-Rieke spring patent. These latter are of steel. Between the steel felloe and the outside steel tire are located some 25 coiled springs, so disposed as to take up all road shocks. The wheel has been given a number of satisfactory tests and is held to be thoroughly practical.

GRAMM TRUCKS IN RUSSIA.

What is claimed to be the first American truck purchased by the Russian government is a Gramm, made by the Gramm Motor Car Company, Lima, O. The vehicle was shipped to St. Petersburg last September for demonstration purposes, and has been in the service of the War Department for the past two months without repairs.

MOTOR TRANSPORTS IN SOUTH AFRICA.

Recent advices from Cape Town in South Africa indicate that there is to be a large increase in the number of motor trucks in use in that section during the coming season. While many of the country roads are not especially good, it is understood that considerable improvement has been made in the Transvaal, and that merchants in Johannesburg and Pretoria are in the market for many cars.

FIRE DEPARTMENT NOTES

During a recent big fire in Richmond, Va., the superiority of the modern fire equipment was demonstrated in a striking manner. Recently, Chief Joynes placed in service a Knox pumping engine, made by the Knox Automobile Company, Springfield, Mass. For 13 hours this machine kept two streams of water going on the fire, practically without intermission, and within a few minutes after it returned to headquarters it was ready for another call.

The alarm was rung in shortly before 6 in the evening, and it was not until 7 the next morning that the recall was sounded. During all this time the chauffeur, who also acts as engineer and mechanician, occasionally poured a bucket of gasoline into the tank and went over the mechanism with an oil can.

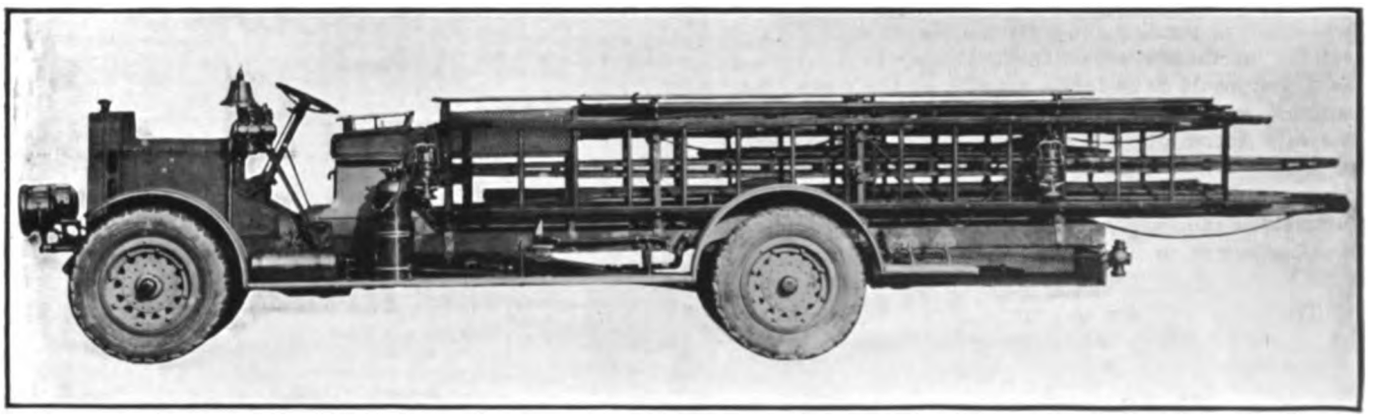
The steam fire engines at work during the same period each required two men, an engineer and a fireman. Their total consumption of fuel is said to have been over 25 tons of steam coal. The bill for running the gasoline pumping engine at full speed for the 13 hours was just $4.50.

This big Knox engine really is an entire fire department in itself. It is propelled by the same motor that works the pumps, a six-cylinder, 60 horsepower unit. It also carries a 35-gallon chemical tank with hose and 1000 feet of water hose. When not in action it has no horses to feed and its cost of maintenance between fires is practically nothing. In addition, it may be stated that it does not require horse wagons to supply it constantly with fuel when working at fires.

An accompanying illustration presents a hook and ladder truck recently supplied to the fire department in Indianapolis, Ind., by the Mais Motor Truck Company of that city. A particular feature of the equipment is the tires, said to be the largest ever manufactured. These are 38 by eight inches in size and made by the United States Tire Company, New York City, upon special order for the Mais concern.

The vehicle was placed in such service that it was essential to have more than ordinary speed possibilities, even for this work, and the truck was designed to obtain 40 to 50 miles an hour without difficulty. In order to accomplish this, the weight is carried very low, and while there are nearly 400 feet of ladders on the wagon, they are nested so closely together that the highest point of the equipment does not measure more than five feet from the ground.

The city of Paterson, N. J., has been progressive enough to purchase two motor driven chemical engines, and these have just been placed in service. The vehicles were made by the Alden Sampson Manufacturing Company, Detroit, a constituent of the United States Motor Company, which placed the order. All of the paraphernalia which is a part of the chemical equipment has been placed in a convenient manner on these trucks, so that quick action is possible when it is necessary for the vehicles to arrive at the scene of the fire.



Alderman James L. Harrop of Worcester, Mass., chairman of the joint standing committee on fire department of the city council, has been in conference with Mayor David F. O'Connell, relative to the purchase of additional motor driven fire fighting apparatus. The mayor is very much in favor of automobile equipment, and took the matter up exhaustively in his inaugural message. The plan contemplates the replacement of horse drawn combination chemical and hose wagons at two stations with the modern equipment.

J. W. Cristie, who is more or less well known in the industry because of his advocacy of the front drive, has brought out a two-wheeled tractor embodying features of this design, for use in hauling steam fire engines. The new vehicle was demonstrated recently in Washington, D. C., Hoboken and Paterson, N. J., and New York City, by C. J. Cross of C. J. Cross & Co., who it is understood will market the product.

A special committee on better protection of property, appointed by the town of Wakefield, Mass., will place an order in the immediate future for a motor driven combination chemical and hose wagon. The committee has $5800 at its disposal.

Many southern cities have been adopting motor driven fire apparatus, to the total exclusion of the horse drawn equipment within the past year. Macon, Ga., is one of the municipalities which gave the plan a trial about a year ago. The remarkable success resulting is best exemplified by the following resolution recently passed by the city council:

"Whereas, the auto apparatus now in use in the fire department has clearly demonstrated its advantages over the horse drawn apparatus, from the viewpoint of lessening expense of maintenance and increase in efficiency, and the use of much less apparatus is approved by the Southwestern Tariff Association; and

Hook and Ladder on Mais Chassis, in Use by the City of Indianapolis, Ind.—Note Tires, Said to be Largest Ever Made.

Digitized by Google

"Whereas, the committee on fire department, after careful investigation, is convinced that the city can effect a further saving from $800 to $900 a year by supplanting the horse drawn apparatus with the motor driven apparatus, besides greatly increasing the efficiency of the department; therefore, be it

"Resolved, That the committee on fire department be, and it is hereby, authorized to begin negotiations at once for the purchase of two auto fire engines and one auto truck, the same to complete the equipment of the department."

Commenting editorially on the subject of securing new fire fighting equipment, the Waterbury American, Waterbury, Conn., has the following to say:

"Here is the point for the consideration of the good citizens of the Walnut street district who seem to prefer a poorly equipped fire house in their own immediate territory to the equipment of existing houses with modern automobile apparatus. On an alarm from the West End today the new automobile engine from the East End reached the scene ahead of the horse drawn apparatus from Scoville street and from the head of Willow street, though it travelled considerably more than twice as far. In other words, the equipping of a house in the East End has improved the West End's fire protection as much as would the establishment of horse drawn apparatus, say in the vicinity of the Green.

"The money required for a new house on Walnut street would furnish three or four pieces of automobile apparatus, and these placed in the Baldwin street, Willow street, Brooklyn and possibly the Burton street houses would protect the northeastern section far better than any equipment they could hope for in a house of their own, besides being of incalculably greater value to the rest of the city. The substitution of an automobile for horses has the effect of moving a fire station at least half and probably two-thirds nearer any given point. With the introduction of automobiles the advantages of having a fire house next door have become more sentimental than real."

Combination Hose and Ladder Wagon Furnished to City of Tupelo, Miss., by Federal Motor Truck Company.

The following cities and towns have appropriated money for or are considering the purchase of automobile fire apparatus: Rochester, Minn.; Shawnee, Okla.; Moline, Ill.; Petaluma, Cal.; Reading, Penn.; Quincy, Ill.; Atlantic City, N. J.; Chelsea, Mass.; Marblehead, Mass.; Southington, Conn.; Watervliet, N. Y.; Bakersfield, Cal.; Johnstown, Penn.; Sandusky, O.; Syracuse, N. Y.; Middleboro, Mass.; Decatur, Ia.; Arlington, Mass.; Brockton, Mass.; Jackson, Miss.; Pittsburg, Penn.; Morristown, N. J.; Hartford, Conn.; Rochester, N. Y.; Somerville, Mass.; Detroit, Mich.; Rock Island, Ill.; West Springfield, Mass.; Rockland, Mass.; Cohoes, N. Y.; Ottawa, Can.; Oklahoma City, Okla.; Binghamton, N. Y.; Macon, Ga.; Lakewood, O.; Manchester, N. H.; Richmond, Va.

At the annual meeting of the town of St. Johnsbury, Vt., an appropriation of $7500 was made for the improvement of the fire department. This led to the purchase of an automobile truck and chemical engine.

Herewith is presented an illustration of the combination hose and ladder wagon constructed for the city of Tupelo, Miss., by the Federal Motor Truck Company, Detroit, about six months ago. This concern furnished the vehicle and equipment complete, with the exception of the ladders. The department in Tupelo reports that it has been doing most satisfactory work.

The chassis is exactly the same as that utilized in the Federal one-ton truck. The four-cylinder motor has a bore of 4.25 inches and stroke of 4.5, and develops 30 horsepower at 1000 revolutions. The cylinders are cast in pairs and are of the L head type, with both inlet and exhaust valves, which are interchangeable, on the right. Cooling is by water, circulated by gear driven centrifugal pump. Lubrication is by splash, and ignition by high-tension magneto, with set spark.

The clutch is a leather faced cone, and is supplied with six auxiliary springs which provide very easy engagement. The transmission and jackshaft unit is so mounted that it can be removed without disturbing any other part, or the transmission alone can be taken out without disturbing the jackshaft. This accessibility of parts is a decidedly important feature in the construction of this truck.

A newspaper in Baker, Ore., held a popular voting contest recently the prize for which was an automobile. It was won by the fire department, which will have the machine fitted with chemical tanks and apparatus for the use of the chief.

REO SAVES MORE THAN COST.

One of the many instances of how the commercial vehicle effects economy is noted in the case of a Reo light delivery vehicle sold some six months ago by R. E. Ingersoll, metropolitan sales manager for R. M. Owen & Co., distributor for the Reo Motor Truck Company, Lansing, Mich. During six months the car covered 4553 miles, making 3773 stops and the cost for gasoline, oil and repairs was $78.86, an average cost of less than 1.75 cents a mile. During its service the automobile has earned $900.54, or $150 more than its original cost. The machine was operated during the severe snowstorms and under conditions when the horse drawn equipment was seriously handicapped.

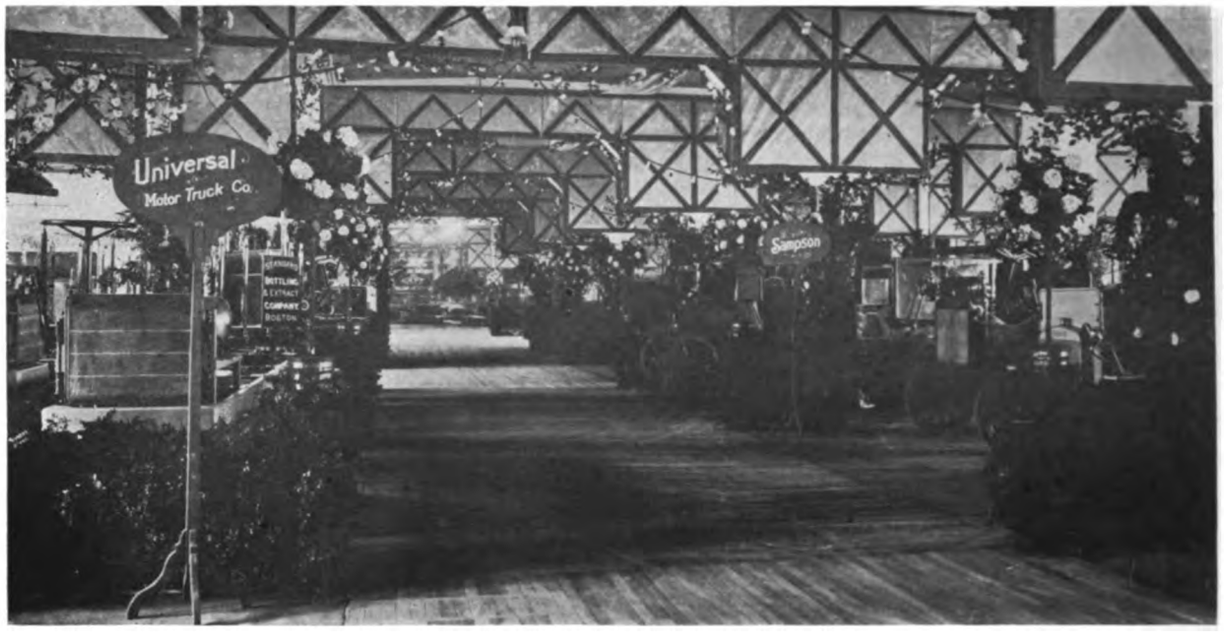
Devoted to Motor Driven Business Vehicles of All Classes.

VOL. III. PAWTUCKET, R. I., APRIL, 1912 No. 4

BOSTON SHOW BOOMS WORLD'S BEST MARKET.

New Trucks and Wagons Develop Much Interest---Many Agencies Made and Individual Sales Far Exceed Expectations---Public Accepts Results of Haulage Inquiries and Changes Methods to Adopt Power Service.

REGARDED from any point of view, the exhibition of power wagons made by the Boston Commercial Motor Vehicle Association, which was concluded March 20, was the largest and most productive ever held in America. It was the first show at Boston devoted exclusively to service wagons and its success was such as to justify the statement that in future these expositions will be the most important of the year. This statement is made advisedly and with a realization of the full value of the show to the people as a whole. It is not based on the desire of the industry or the trade, but upon the demand of the whole people for education in a subject that means more to them than any other. The service wagon is regarded primarily as being a means for economy in industry and commerce. As such it has been exploited and its utility developed. But its usefulness may be applied to every form of transportation. Through its use the business man may extend his activities, affording to the public the advantages obtaining from the larger and carefully organized enterprises. The cost of transportation may be said to be equal that of production. This may be the better realized from the enormous development of railroads and other means of public service. The United States is a nation of magnificent distances and each mile between communities has a distinct commercial value. There has been but little attention directed toward distribution with a view of economizing selling values. Production is seldom near the supply of raw material. There has been some consideration of this phase in metal producing and in textiles, but establishing the market cost has never been with reference to supplying the people at the lowest price that could be consistently charged. Competition has invariably dictated prices, if the market be uncontrolled.



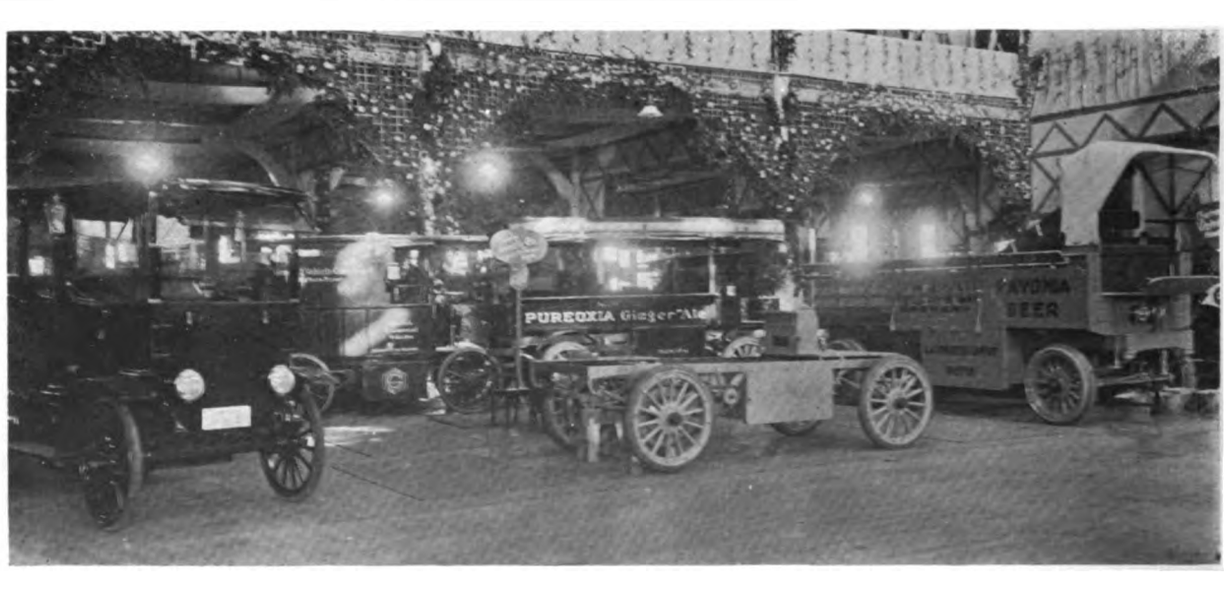
Looking Across Grand Hall from the Balcony, Showing the Power Wagon Display in Decorations Representing a Spanish Mission Scene.

It is entirely practicable that business development should influence the market. It is also a fact that activity should correspondingly affect it. That is to say, that it is possible through a lessened cost of transportation and delivery to make lessened prices, this being the logical manner of obtaining public patronage. This reduction of haulage may be accomplished by the power vehicle by performing a given service with less expense as compared with animal transport; by doing more work for no greater expenditure; by doing more work at no greater proportionate expense; by doing more work at less cost.

These facts are realized by the people who have given the subject of haulage serious consideration. The possibilities for business have been deliberated and established. With animal transportation the limitations were understood. Beyond them no one cared to venture. Some large enterprises have undertaken to extend their markets but the cost is necessarily much larger and the service has been given at what might be regarded as a loss. But with the knowledge that the service vehicle is in every way dependable and economical the business men have found themselves facing what is no less than a revolution in methods. During the period since the practicality of motor conveyances was established there has been conviction that eventually the mechanical vehicle would be generally, if not universally, adopted for all purposes save construction within the natural limitations. The barrier has been ignorance of the actual cost of animal service and inexperience with that afforded by motor driven transports.

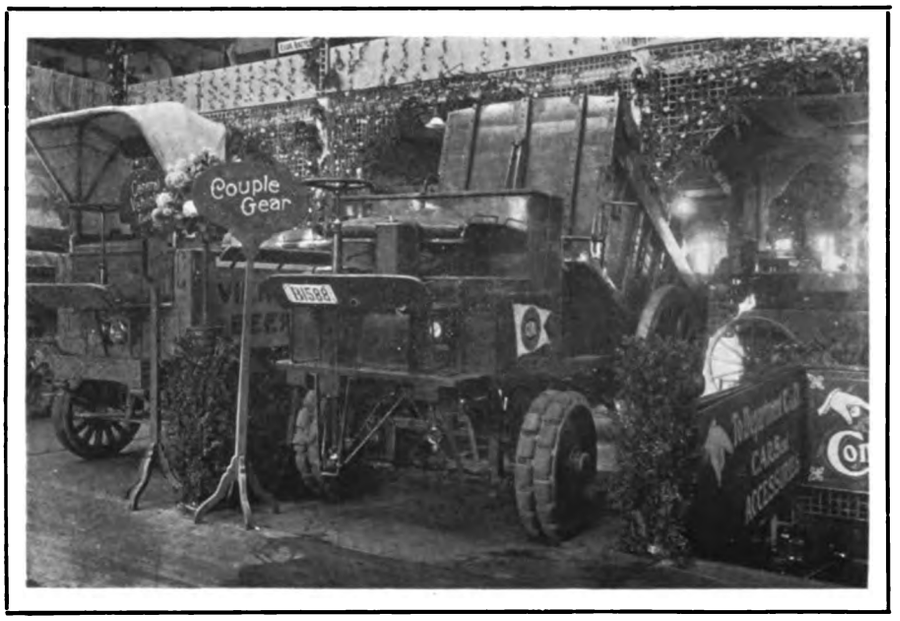
The point has now been reached when the value of the service wagon has been established. Its utility is acknowledged and its economy is not questioned. It is no longer an experiment. But there is realization that it is imperative

Digitized by Google



Looking Down a Long Aisle in Machinery Hall with Its Decorations Suggesting an Old English Rose Garden in the Early Spring.

to change the methods of delivery and distribution to obtain the fullest benefits of the improved service. The concentration of the attention of the business man has in the past been on his own affairs. He has met the problems as they have appeared and worked out solutions to best serve his purposes. He has been entirely satisfied with his results. While apparently similar, it is found upon analysis that there are conditions entirely different with two concerns engaged in the same business.



The manufacturer of service vehicles has been compelled to educate the people to the actual business necessities and requirements. He has been forced to begin with his selling agents and impress upon them the possibilities for mechanical transport service. Then in turn it has been necessary to deal with all business interests to demonstrate the practicality of the conveyances. Next it has been found imperative to study each individual need and to work out solutions that are so thoroughly practical and convincing that the service vehicle has been adopted. Conditions have been normal and logical aside from the fact that the business man had not been willing to apply to his own use information that had been worked out by those who had studied the subject because, in his opinion, he was not satisfied that what obtained with others did obtain with himself. He has been willing to accept every other business principle without question and has been guided by custom and precedent, but in that concerning which he should be the best informed he has been absolutely ignorant.

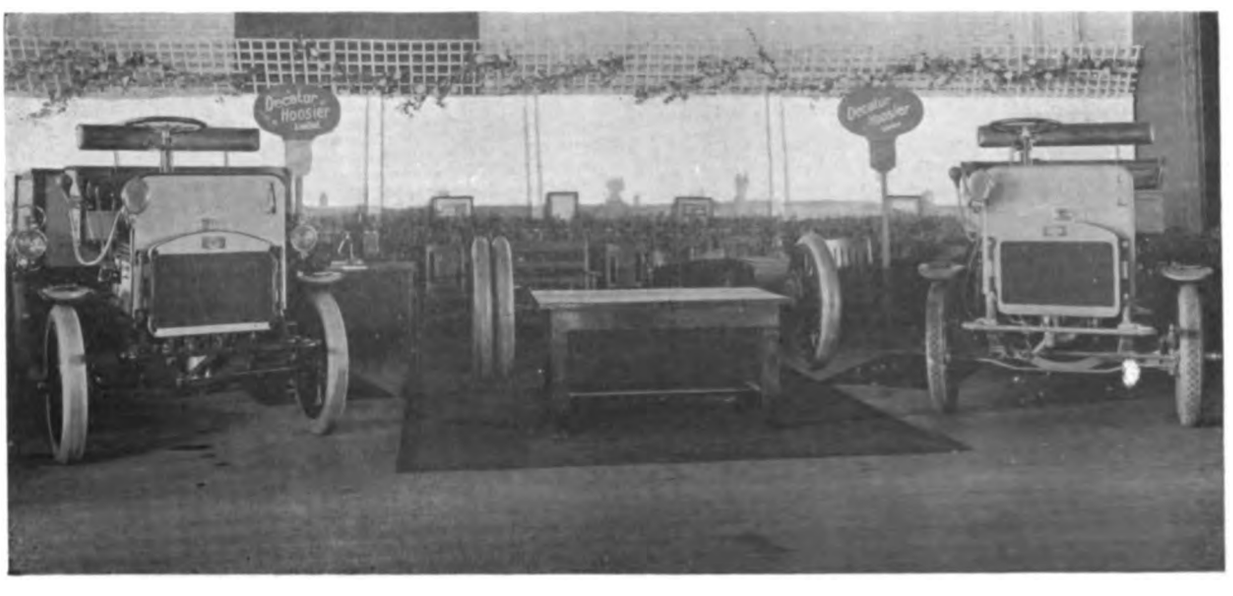
The organization of the service wagon show at Boston has been extremely beneficial to the business interests in that the vehicles, always shown heretofore as secondary to pleasure automobiles, have been given the prominence they should have and the exhibition has made possible the showing of a much larger number of makes, and of each type. This has resulted in first stimulating interest in the machines themselves, as there is competition in the exhibits in everything save service. This interest has impelled consideration of the different types in each class, and the

A Glance Into the Stand of the General Vehicle Company, Showing a Special Ambulance, Delivery Wagons, a Brewery Truck and a Chassis.

Digitized by Google

Democratic Vehicles, Couple-Gear Gravel Cart and a General Vehicle Brewery Wagon, Amid the Hedges and Climbing Roses.

adaptation of these machines to differing service. To make clearer the result it may be said that study of a condition may establish that a specified work may be done more economically and satisfactorily with another size or type of machine than was contemplated.



But the main value to the industry and the trade is in the fact that those who visited the exhibition have a sufficient concern to consider service wagon use and to take up the study of utilization. The importance of this to the manufacturer and the distributor is manifest. It has placed the industry on the same commercial basis that may obtain with any other. It has convinced the man of business that it is absolutely necessary for him to devote his attention and endeavors toward what has been neglected, and which must be improved to the fullest extent.

Largest Motor Truck Show.

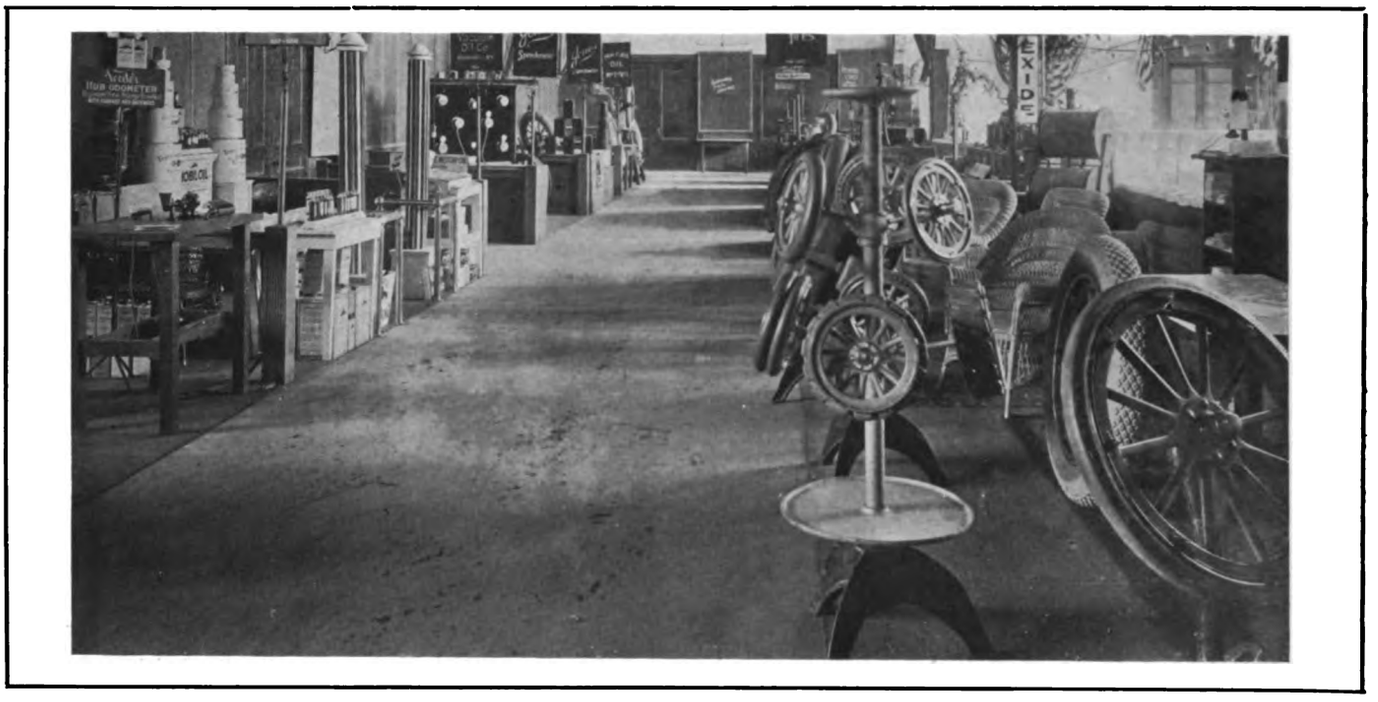
The Boston service wagon show was the largest exhibition of these vehicles ever held under one roof. This fact means more than may appear without reflection, for not only were all vehicles so displayed that comparison could be readily made, but there was certainty that all received the same attention. There is no question that it would be far better from the viewpoint of the visitor were the machines shown in classes and each class separated, departmentalizing by character and capacity of vehicle, but this is not possible under the system where there is a choice for space in the entire show. Were the exhibitors limited in their space selection to any given department this would seemingly eliminate a condition that was found to be decidedly unsatisfactory from the standpoint of the man who desired to see all of a certain class of machines and was compelled to search through the entire exhibition, with no assurance that he had found all that might interest him.

In addition to this there was a material delay of some of the exhibits, which was a distinct loss to the disappointed exhibitors, for in at least one instance a machine, and the only one of the make shown, was not received in the show until the last day. Others, for which space was engaged, did not arrive. One reason was the endeavor of some of the manufacturers to make display at other shows, suffering transportation delays that were of such a nature that only by allowing the greatest margin could the machines have been received for the opening. It is obvious that to take any chance that would curtail or prevent display at so important an exposition was ill advised. It is quite as evident that competition demands that every opportunity to obtain publicity should be accepted. To make exhibition after announcement of such showing is a duty that should be fulfilled, for the people who may have been attracted by that particular exhibit ought to be considered.

The number of complete wagons shown was 182, and the chassis numbered 42, this making a total of 224. In all 61 different makes were represented. The number engaging space for vehicle exhibition and entitled to representation was 64. It will be seen that average number of vehicles to exhibitors was approximately 3.66, but as a matter of fact six exhibits constituted about 33 per cent. of

Where the Decatur "Hoosier Limited" Was Displayed, the Exhibit Consisting of a Complete Vehicle and a Chassis.

Digitized by Google



the entire show, and 10 displays about 45 per cent., leav- for the other 51 about 55 per cent. Regarded simply from the number of machines shown and the proportions as indicated, it must be admitted that the possibilities of a real buyers' exposition, such as the Boston show has always been, were not understood by many. This is not criticism of those who had a single vehicle to represent them, but it is meant to emphasize that those who expected to obtain the largest returns of business made demonstration of the differing forms of chassis and equipment as their spaces would permit.

It is hardly necessary to point out how essential it is for the man who is examining the exhibits in a show, with the intention of buying or of changing his haulage equipment, to see as many bodies as can consistently be shown, for few men can conceive the possibilities of the bare chassis. If assisted by a body building expert it might be possible to draw fairly reasonable approximations, but the man who has practically no knowledge of body construction may be regarded as almost helpless. There are instances where but a single form of body is fitted to a chassis, but these are extremely infrequent, and it might be said that it is entirely practical to install any one of many types of construction upon a single chassis.

There was one condition manifest that should receive the most careful consideration of the exhibitors. Of the number actually showing service wagons 22 had exhibits at the pleasure car show. The strain of preparation for both exhibitions and the display and demonstration, with the additional work created by the general promotion of interest by the first show, and the inability to secure the experienced salesmen and demonstrators temporarily needed, was severely evidenced. The demands upon the exhibitors and their assistants by increased business and the activities of the show were such that the men were thoroughly exhausted and subjects that should have been given the closest attention were neglected or deferred. The interest in the service wagons was a sufficient reason to justify the exhibitor giving to each visitor every attention, yet in some instances displays were in the care of but one person for considerable periods, causing those desirous of obtaining information long waits and very evident impressions of business laxity or negligence, which were entirely unnecessary.

The Search for Knowledge.

If there was one thing impressed upon those who observed the show and its visitors it was that a prospective purchaser of a vehicle was systematic in his search for knowledge, and while there may not have been a specific object in mind at the outset there was unquestionably a class found suited to certain purposes that impelled and received attention. This fact differentiates the service wagon exhibition when contrasted with a pleasure car show. With the prospective buyer of a wagon or truck, capacity with reference to the operating conditions is the main desideratum. There may be differing values with a single classification, but service is the first and last quality sought, and this must be first of all determined by capacity. It may be possible for the purchaser to determine such systematizing of his delivery and haulage that he can adapt larger vehicles than were first considered, and it may be practical to turn from the large to the smaller by adopting another system, but under ordinary conditions the buyer must be attracted by what appears to be adapted to his purposes and within his financial reach.

The East Aisle of the Main Accessory Department Looking Toward Paul Revere Hall, with the Kelly-Springfield Tire Company's Display in the Foreground.

From the attitude of the exhibitor the show at its conclusion was a success because of its remarkable productiveness. The visitors were buyers and the exposition was hardly inaugurated before "sold" signs appeared, and as the exhibition progressed these were greatly multiplied. Business was transacted by all who had stands, and with rare exceptions the transactions largely exceeded expectations, for it was very generally assumed that while there would be prospects developed these would, if from a distance, conclude negotiations through the community representatives. The sales made were of all types of vehicle. The transition from animals to power is not confined to any classes of industry or commerce. There were, however, certain enterprises that were directly attracted toward wagons of large capacity, these including those dealing with freight and express haulage, coal, ice and building materials, contractors, builders, and others requiring the transportation of heavy and bulky loads.

The approach of warmer weather and the resumption of construction work of all kinds was a cogent reason for the

Digitized by Google

keen concern manifested by those engaging in such undertakings, and the anticipated activity in the coal and ice markets, as well as the impending removals of thousands from winter to summer residences had the effect of stimulating those who transport them to preparations to meet with the expected increase in demands. But beyond this was an intense desire to acquire information relative to all manner of transportations. One of the facts strongly impressed upon the observer was the acceptance by those in business of the knowledge of the manufacturers and salesmen of all conditions of haulage. There was recognition of the careful study of the subject as a whole and understanding that what had been regarded as theory was accurate information based on careful compilation of data accumulated from innumerable sources.

Until now there has been general assumption that it is impossible for a man, however expert, to determine the relative expense of animal and motor transports, but it has been proven by statistics that cannot be rejected that there is not only a sufficient economy to justify the adoption of the service wagon, but as the animal vehicles are eliminated there will be a saving proportionate to the use of the power conveyances. The realization of the proportions of the haulage problem and the possibilities for service vehicles has been very general and there is reason to believe that there will be as the result of the show a constantly increasing market for all forms of wagons and trucks.

One evidence of this was the considerable number of agencies made by makers and distributors. This insures to many active representation in localities that had previously been neglected and which are regarded as extremely promising. The opinion is well established that there ought to be the same constant market for service wagons that has obtained in the past with animal vehicles, and there is a prevailing belief that the establishment of service stations that will afford to those whose requirements are not such as to justify a private garage whatever attention is necessary or desirable, is the next logical development.

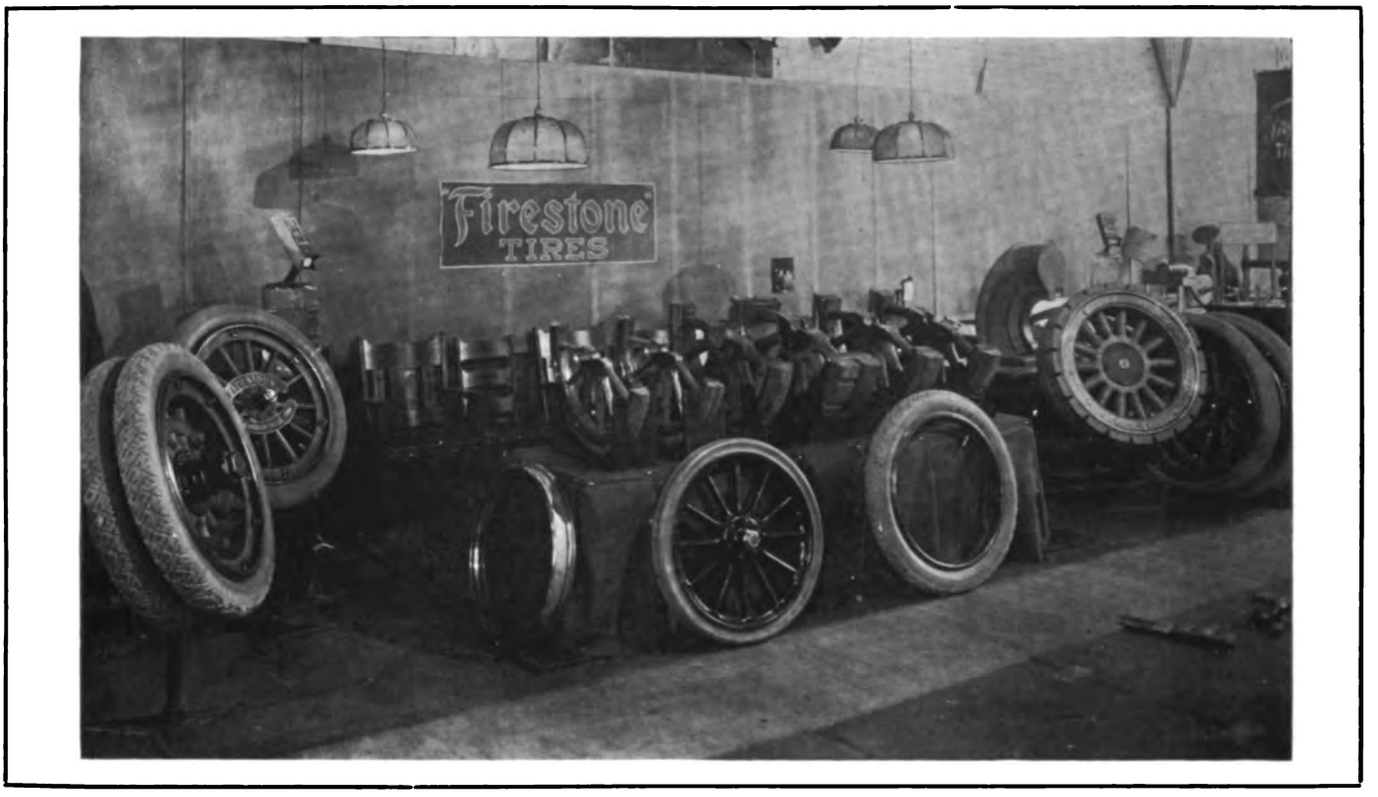
Details of the Exhibits.

The exhibits were as follows:

Alco—One two-ton and one 3.5-ton truck, and one five-ton chassis.

Atterbury—One 1500-pound delivery wagon, one one-ton delivery wagon, one 1.5-ton delivery wagon, one two-ton delivery wagon, one three-ton truck, one 20-passenger omnibus.

Autocar—Six 1.5-ton delivery wagons, one ambulance, one 15-passenger omnibus, one 1000-pound chassis, one 1500-pound chassis.



Bessemer—One one-ton delivery wagon.

Buick—Four one-ton delivery wagons, one combination chemical fire apparatus.

Baker electric—Two 1000-pound delivery wagons, one two-ton chassis.

Chase—One one-ton delivery wagon, one 1.5-ton delivery wagon.

Clark—One three-ton truck.

The Exhibit of the Firestone Tire & Rubber Company, Which Consisted Wholly of Shoes Designed for Heavy Vehicle Service.

Commer—One 6.5-ton dumping body truck, one 6.5-ton chassis.

Commerce—Two 1000-pound delivery wagons, one 1000-pound chassis.

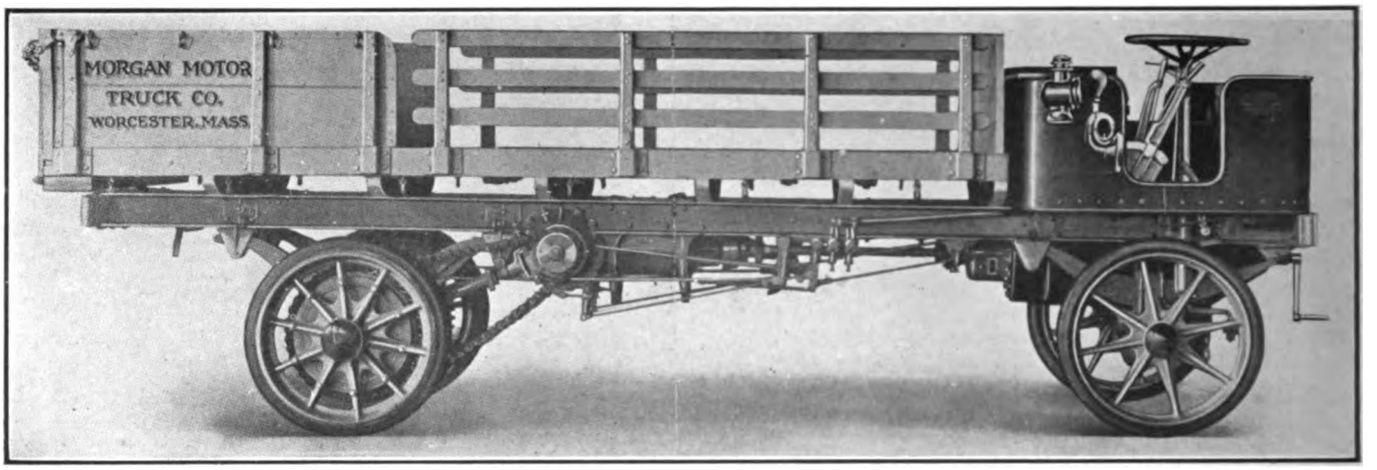
Couple-Gear electric—One five-ton dumping cart, one five-ton bottom-dumping wagon.

Chalmers—One 1000-pound covered delivery wagon.

Decatur—One 1.5-ton delivery wagon, one five-ton chassis.

Dayton—One 1.5-ton delivery wagon, one three-ton truck, one five-ton chassis.

Eckhard—One five-ton chassis.



Ford—One 700-pound enclosed delivery wagon.

Federal—Two one-ton delivery wagons, one one-ton chassis.

G. M. C. gasoline—One one-ton delivery wagon, two two-ton delivery wagons, two 3.5-ton trucks, two five-ton trucks, one two-ton chassis, one 3.5-ton chassis.

G. M. C. electric—One four-ton truck, one five-ton truck,

one three-ton chassis.

General Vehicle electric—One one-ton delivery wagon, two two-ton delivery wagons, one five-ton truck, two two-ton chassis, one ambulance.

Grabowsky—One one-ton delivery wagon, one five-ton chassis.

Garford—One 1.5-ton delivery wagon, one five-ton chassis.

Gramm—One one-ton delivery wagon, one two-ton delivery wagon, one three-ton truck.

International Harvester—One 1000-pound delivery wagon, one 1500-pound delivery wagon, one 2000-pound delivery wagon.

KisselKar—One one-ton delivery wagon, one two-ton delivery wagon, one three-ton truck, one one-ton chassis, one four-ton chassis.

Kelly—Four 1.5-ton delivery wagons, five three-ton trucks, one four-ton truck, one omnibus on 1.5-ton chassis, one sightseeing wagon with 1.5-ton chassis, one 1.5-ton chassis.

Koehler—One 1600-pound delivery wagon.

Knox—One two-ton delivery wagon, one three-ton truck, one six-ton chassis, one patrol wagon, one combination hose and chemical fire wagon, one 60 horsepower fire pumping engine and combination apparatus, one Martin tractor.

Lauth-Juergens—One three-ton truck, one one-ton chassis.

Locomobile—One five-ton chassis, one combination hose and chemical fire wagon.

Lozier—One five-ton chassis.

Lansden electric—Two one-ton covered delivery wagons.

Mack—One 1.5-ton furniture wagon, three two-ton delivery wagons, one three-ton furniture van, one three-ton oil tank truck, one five-ton brewery truck, two five-ton coal dumping body trucks, two seven-ton gravel dumping body trucks, one two-ton chassis.

Mais—One 1.5-ton delivery wagon, one two-ton delivery wagon, one 1.5-ton chassis.

Martin—One three-wheeled tractor.

Mercury—Three 1000-pound delivery wagons.

Modern—Three 1500-pound delivery wagons.

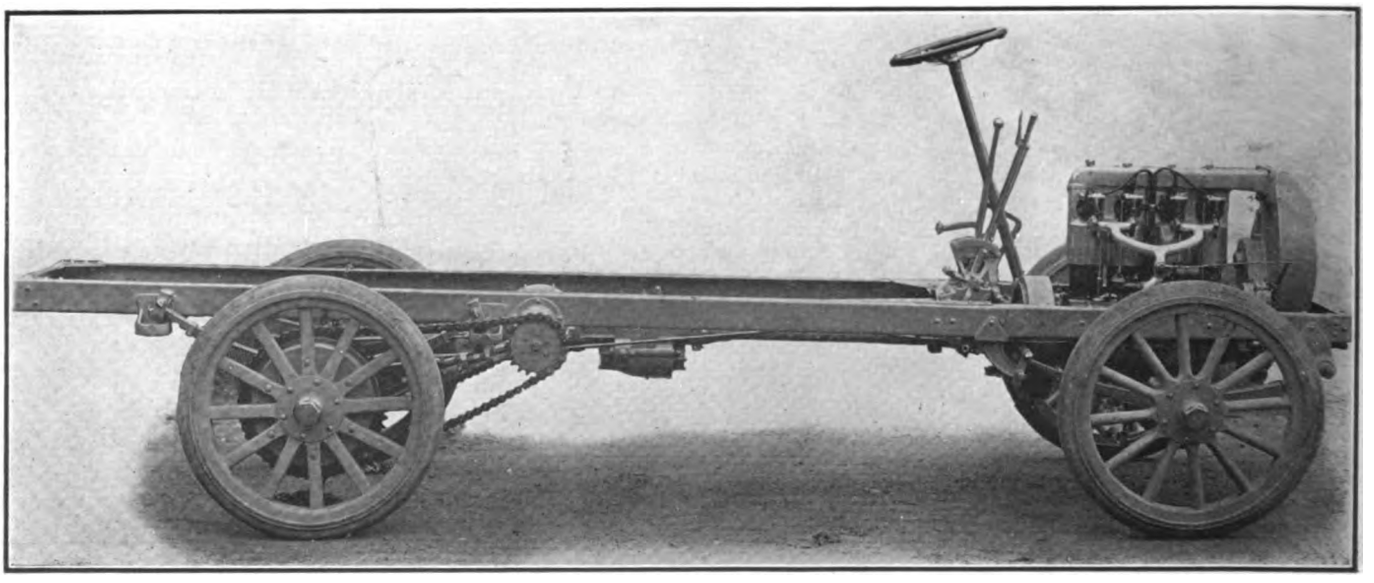
Mora—One 1000-pound delivery wagon.

Morgan—One two-ton delivery wagon, one three-ton truck, one five-ton truck.

Motor Wagon—Two 1000-pound delivery wagons.

McIntyre—One two-ton delivery wagon.

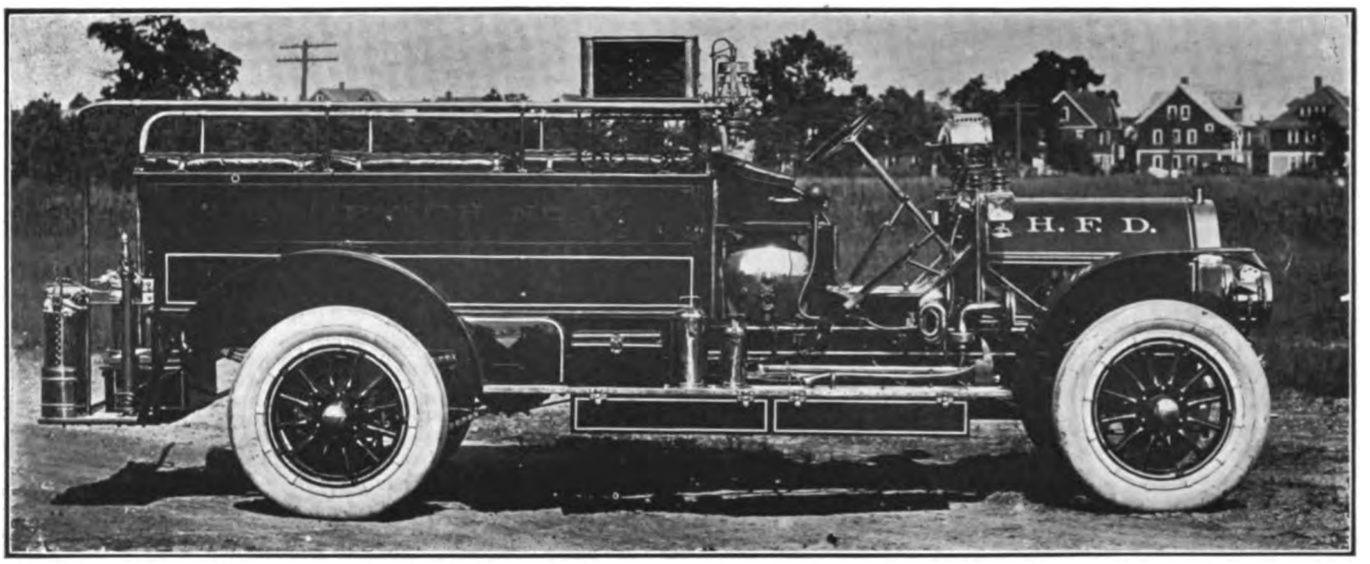
Packard—Eleven three-ton trucks with different body equipments, one two-ton truck, one two-ton chassis.



Peerless—One three-ton truck, one four-ton truck, one five-ton truck, one three-ton chassis.

Pierce-Arrow—Three five-ton trucks, one with dumping body, and one five-ton chassis.

Pope-Hartford—Two three-ton trucks and one combination chemical and hose fire apparatus.



Poss—Two 1000-pound delivery wagons.

Sampson—Two 1000-pound delivery wagons, two 1.5-

Combination Chemical Engine and Hose Wagon Equipment Installed on a Knox Chassis.

ton delivery wagons, one three-ton truck, one five-ton truck and one five-ton chassis.

Sanford—Two one-ton delivery wagons.

Sandusky—Two 1.5-ton delivery wagons.

Speedwell—One two-ton delivery wagon, one four-ton truck and one six-ton truck.

Stanley steam—One one-ton delivery wagon, one 12-passenger omnibus.

Stearns—One five-ton truck.

Sternberg—Two two-ton delivery wagons, one four-ton chassis.

Saurer—One 4.5-ton truck, one 6.5-ton brewery truck, one 6.5-ton chassis, one fire pumping engine.

Overland—One 1000-pound delivery wagon.

Reo—Three 1500-pound delivery wagons.

Teel-Woodworth—Two three-ton trucks, one three-ton chassis.

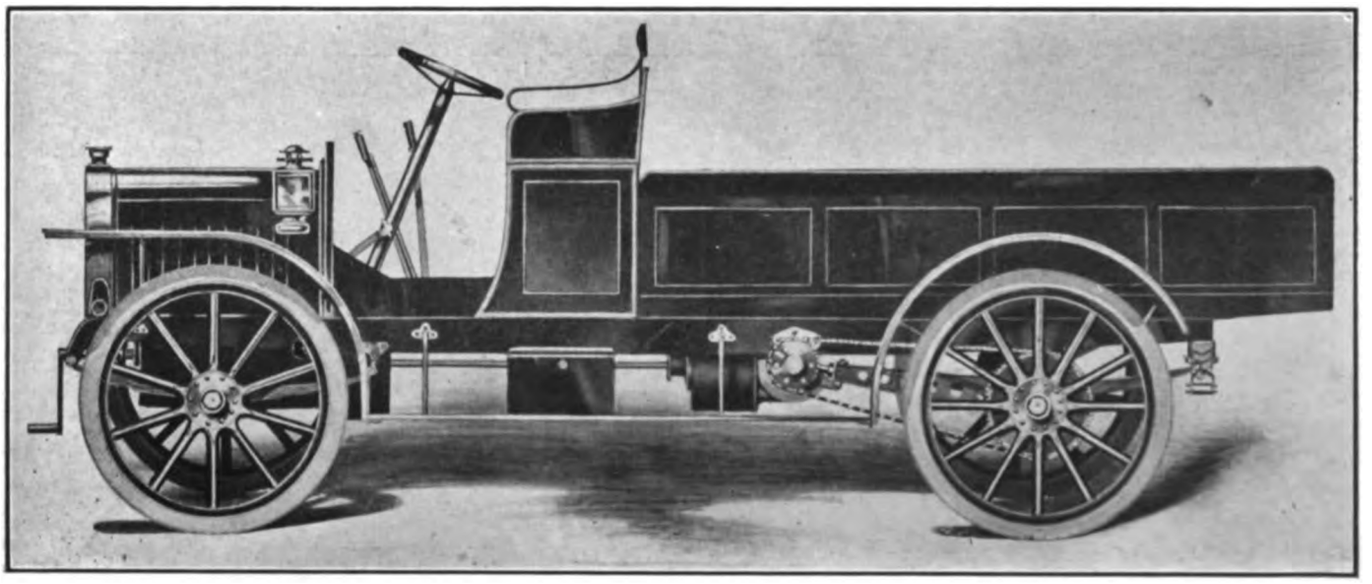
Velie—One three-ton truck, one three-ton chassis, one five-ton chassis.

Victor—One 1.5 ton delivery wagon, one 3.5-ton truck.

Walker electric—Two one-ton delivery wagons, one one-ton chassis.

White—One 1.5-ton delivery wagon, one two-ton delivery wagon, four three-ton trucks, two five-ton trucks, one 1.5-ton chassis, four three-ton chassis, one five-ton chassis.

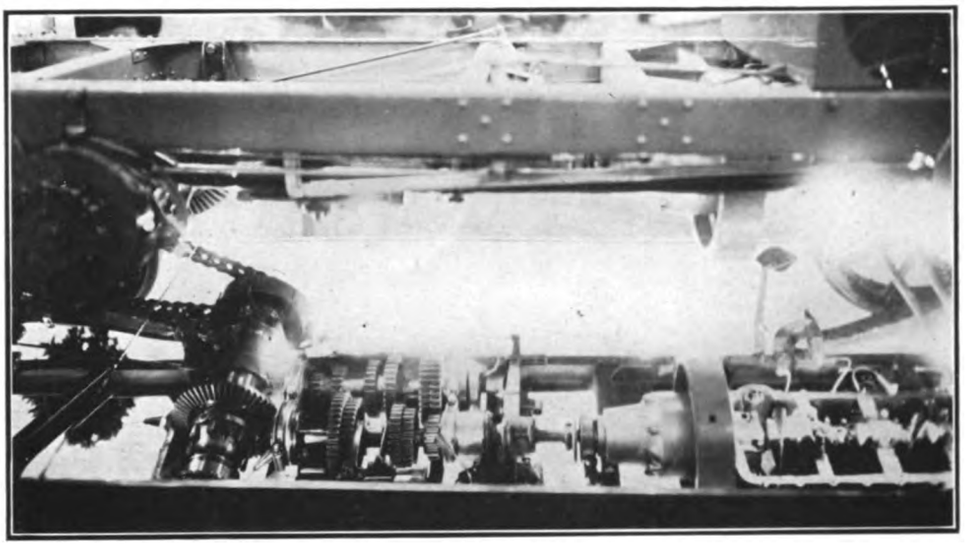
Waverley electric—Two 1500-pound delivery wagons, one 1500-pound chassis.



Seen for the First Time.

The makers of wagons shown for the first time at any show were the Clark, Eckhard and Stanley. Those displayed for the first time at any national exhibition were the Chalmers, Couple-Gear, Ford, Mora and Teel-Woodworth, and the Mais was seen for the first time at any 1912 show.

The makes that were not represented at the 1911 exhibition were the Bessemer, Baker electric, Chalmers, Commerce, Federal, Gramm, G. M. C. gasoline, G. M. C. electric, KisselKar, Koehler, Lansden, Lauth-Juergens, Locomobile, Lozier, Mack, Mais, Mercury, Modern, Mora, Motor Wagon, Martin tractor, Pope-Hartford, Poss, Reo, Sandusky, Sanford, Saurer, Stearns, Sternberg, Velie, Walker and Waverley.



The makes that were displayed in 1911 were the Alco, Atterbury, Autocar, Buick, Chase, Commer, Dayton, Decatur, Garford, Grabowsky, General Vehicle, International Harvester, Kelly, Knox, Morgan, McIntyre, Overland, Packard, Peerless, Pierce-Arrow, Sampson, Speedwell, Victor and White.

Those that made display in 1911 that did not engage space included the Atlas, Beyster-Detroit, Brush, Cass, Detroit electric, Franklin, Harder, Harrison, Hupmobile, John-

Locomobile Five-Ton Truck Chassis, Exhibited Above a Mirror with the Mechanism Exposed So That the Construction Could Be Clearly Seen.

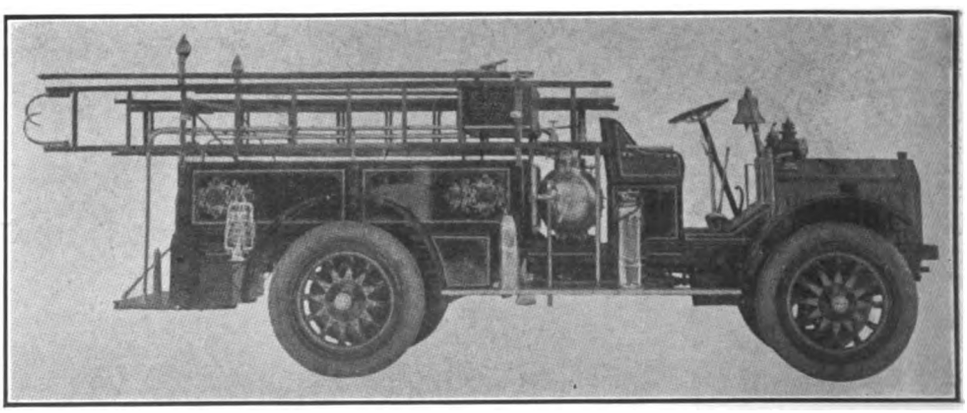
son, Randolph, Stoddard-Dayton, Warren-Detroit and Wilcox. The Rapid and Reliance have been succeeded by the G. M. C. gasoline vehicles, and the Ford taxicab and the Clark two-cycle motor truck were succeeded by the machines stated above.

The largest number of chassis shown was 14, the Kelly and the White each making that display. The Packard was second in point of numbers with 13, the Mack and G. M. C. third with 12 (both electric and gasoline being shown by the G. M. C.), the Autocar fourth with 10, the Sampson fifth with seven, the Atterbury, General Vehicle and Knox sixth with six each. Of the other exhibitors three showed five chassis, three four chassis, 19 three chassis, 14 two chassis, and 12 but one chassis.

The largest number of bodies shown of any one make of chassis was by the Kelly trucks, all the chassis being fully equipped save for one polished 3000 pounds capacity machine. Next was the Packard which showed 12 complete trucks and one chassis in the lead. Third in this classification was the G. M. C. with nine bodies, and the White and the Autocar were fourth with eight bodies each. Somewhat out of the usual manner of exhibition was the showing of the Koehler wagon, there being one chassis with an enclosed body and two bodies of other types, this giving the visitors opportunity of examining the equipment and passing upon the qualities as shown.

The Matter of Motive Power.

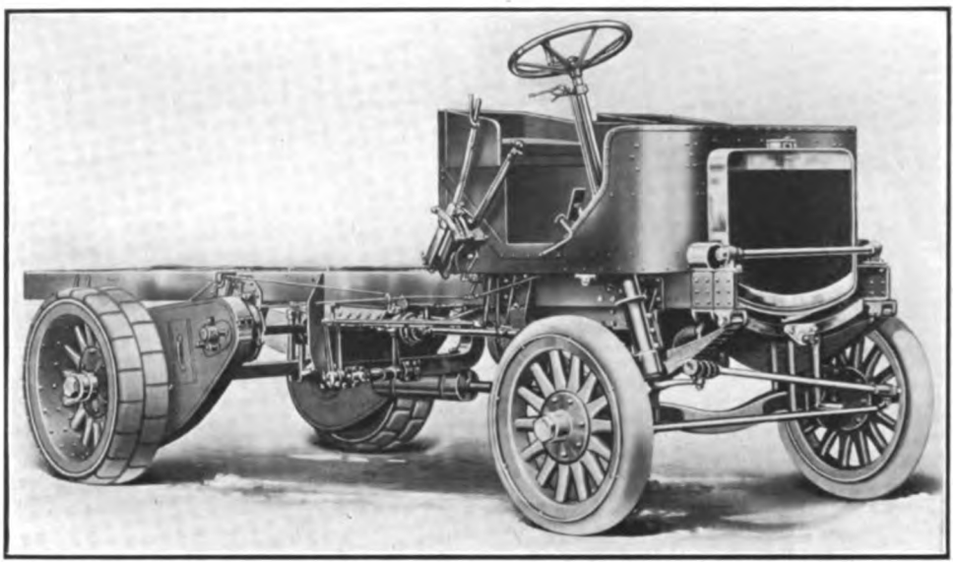
With reference to the motive power of the vehicles 53 makes were fitted with internal combustion engines, and of these 48 were of the water-cooled type, there being the Chase, International Harvester, Mercury and Sanford in the air-draft radiation classification, and the Kelly with blower cooling. Of the others the Baker, Couple-Gear, G. M. C., General Vehicle, Lansden, Walker and Waverley are electric motor driven, and the Couple-Gear and the Walker are equipped with wheel drive. The Stanley machines are fitted with steam engines in every way similar to those used in the Stanley pleasure cars, but the chassis construction is different.



While there was a gain of 19 different makes of cars in the total of exhibitors one of the conditions that emphasized itself was the increase of the electric wagons and trucks. The gain was from two a year ago, and while the Baker, Walker and Waverley are of the delivery wagon type, the Couple-Gear installations have been with particular attention to slow and heavy work and the G. M. C. vehicles are designed for moderate and heavy loads. There has undeniably been an interest created in electric machines that are intended for all classes of service and the attention of the manufacturers has been directed toward undoubted advantages of these vehicles for certain service. In the utilization of electric wagons the very rapid increase in the number of stations where energy may be obtained, and the preparations made by lighting and power plants to include vehicle battery charging as a public service, one of the obstacles to more general use has been largely dissipated, especially in the East, where these stations are to be found and where the price for charging has been uniformly established.

That the distance is really no serious condition was practically demonstrated when a Walker delivery wagon was driven from New York to Boston, the conditions being at least the average of a winter, at a speed approximating 10 miles for the time actually on the road. The wagon was exhibited at the show as it came over the road. The battery was given a "boost" wherever there was opportunity and the wagon was driven with ample reserve under all conditions of use.

Rated as to Capacity.



In considering the different vehicles exhibited and their capacities it will be realized that approximately 70 per cent. were of three tons or less, and it is interesting to reflect upon the following figures, which indicate that the wagons and trucks are types that ought to have material rapidity of movement. The summary demonstrates the following facts:

Capacity, pounds	Number shown	Capacity, pounds	Number shown
700	1	7,000	7
1,000	22	8,000	6
1,500	9	9,000	1
1,600	1	10,000	29
2,000	26	12,000	2
3,000	28	13,000	4
4,000	27	14,000	2
6,000	44		

The Kelly 1.5-Ton Chassis Equipped for Fire Service as a Combination Hose and Chemical Apparatus.

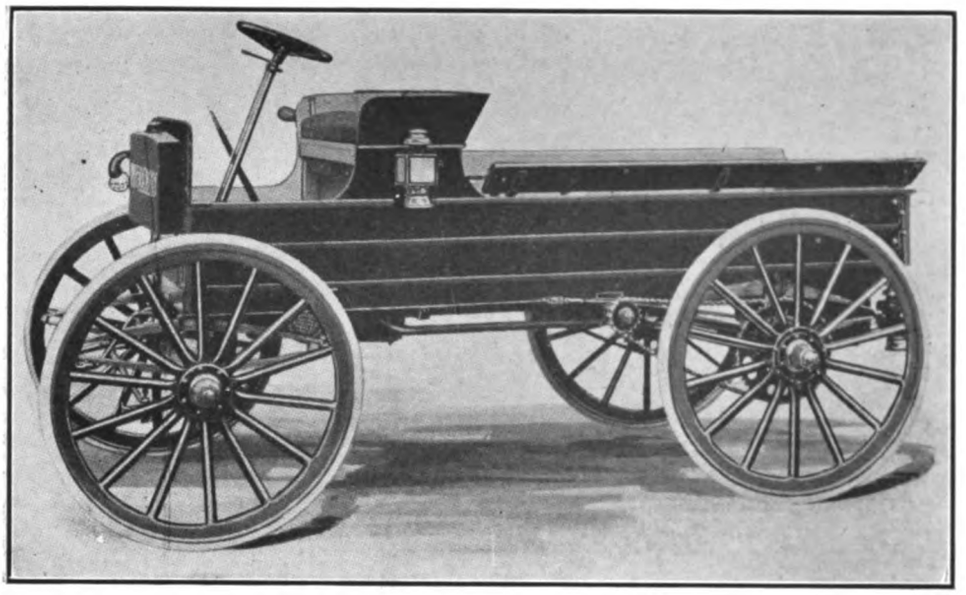
Digitized by Google

The Knox Truck Chassis of Six Tons Capacity, This Machine Being Displayed for the First Time in Boston.

Regarding these figures as fairly representative it will be understood that the representation is largely of vehicles that may be classed with heavy express wagons, there being a very uniform demonstration of the different classifications. The light wagon may be assumed to have capacity of 1000 pounds, the medium wagon from 1000 to 3000 when drawn by a single horse, the heavy wagon from 3000 to 5000, the light truck or dray from 5000 to 7000, the heavy cart or truck from 7000 to 10,000 when drawn by three or four animals. For unusually heavy service the dray or truck may be specially constructed to have capacity in excess of these figures. It will be understood that the reference to animal vehicles is made with the view of making clear the types of service wagons that may be regarded as suited for similar requirements.

A glance at these figures will also show that despite the supposition that the power wagon is necessarily heavy and has very large capacity the larger number of the machines purchasable in the market are what may be adapted to practically any haulage. Another fact impressed upon the observer is that the makers are producing wagons that are light, comparatively high powered, and with such speed as to justify a conclusion that they could be well adapted for delivery purposes.

The opinion prevails very generally that the greatest economy of the service wagon is in superior speed, next in its greater capacity, then in its uniformity of work for a considerable period, and in its reserve as compared with the animal. It is also assumed that increased load is the most potent qualification, especially if the hauls are long, but it would appear that the opinion of the designer and maker is that the largest utility obtainable is comparatively small loads and material speed. Though it cannot be said that the exact aspect can be obtained from a single exhibition, it is entirely reasonable to base a conclusion on a display that is in every way representative with reference to the industry, the trade and the market.



Relative to trucks of 10,000 pounds capacity or more the equipment was designed in the greater number for haulage of coal, ice, gravel and building and construction material. Being designed for such service the bodies were generally fitted with means for quick discharge. Some of the bodies, especially those installed on White, Peerless, Sampson and Alco trucks were elevated by power hoists. These were of differing types, those of the White and Alco being arrangements of compound gears, that of the Peerless by a worm and nut, and that of the Sampson by an air compressor. These hoists were all fitted with stops so that the power might be automatically stopped when the bodies reach maximum elevation, there being no possibility of mishap in the event of carelessness by the driver or operator. The principal purpose was primarily to minimize labor and expedite the time of discharging. The elevation of any body means a gravity discharge into chutes or through end gates, an entirely satisfactory method under some conditions, but for the unloading of coal in the street, especially if the way be narrow the side discharge is desirable. This is accomplished with the Monahan body equipment of the six-ton Speedwell truck by forward or rear side outlets, in addition to the large end gate, by which the coal may be carried across walks or to manholes by chutes. This machine is equipped with a hand hoist by which the body may be raised to a maximum of 42 degrees by the driver in two minutes.

The Morgan coal truck is shaped internally with the sides and ends forming a hopper with sides inclined about 35 degrees. The load is discharged through an outlet at the right side by a huge worm that revolves in a channel into which it descends by gravity and into an adjustable circular chute that may be extended from the side direct to a manhole or coal bin inlet. The majority of the other coal or building material trucks, including the Pierce-Arrow, Packard, Peerless, Kelly, Mack and Commer, were equipped

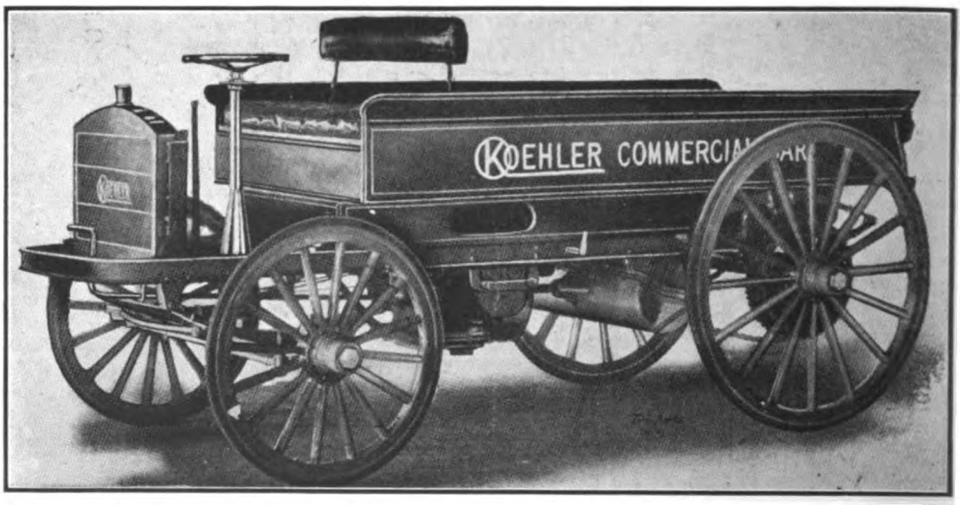
Digitized by Google

The Mercury Delivery Wagon, This Chassis Having an Opposed Cylinder Air-Cooled Motor and Transmission in a Unit Assembly.

with hand hoists and the discharge was generally at the rear gate. There is no question that the power hoist has many advantages and is desirable equipment, but most installations may be adapted to any truck. The expedition of unloading is a weighty factor with those who are engaged in construction and contract work and there is but little doubt that there will be special attention directed toward the improvement of the facilities that are now available.

Distribution of Load.

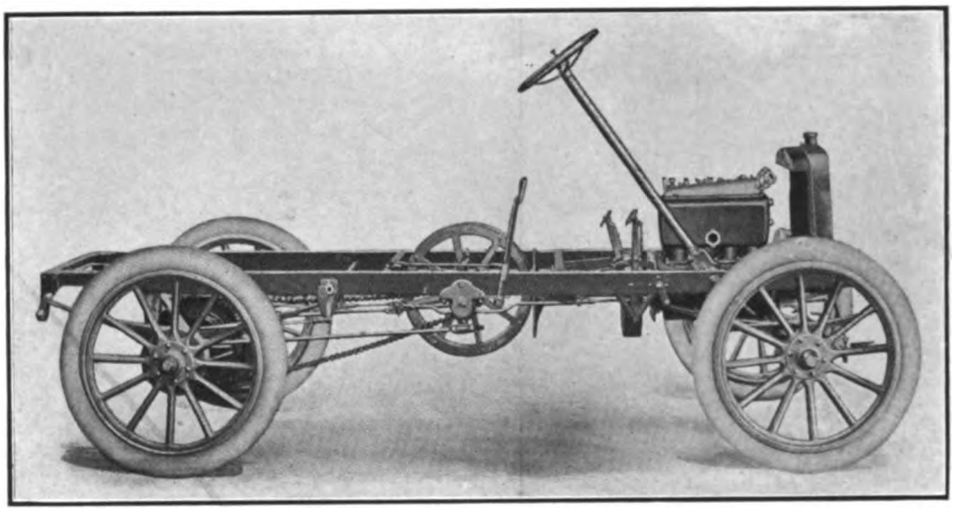
With many of the bodies carried on trucks it would appear that the one condition that could be studied advantageously is that of the location of the centre of load gravity. With the general construction the increased tread is a result of the width of the wheel rims, the ribs being often 12 or 14 inches wide, and this means from 24 to 30 inches must be allowed aside from a reasonable clearance outside of the driving chains. With many chassis the frame is carried above the rear springs instead of being suspended between them, and to permit sufficient compression and recoil of the suspension to absorb the shocks, the frame is considerably above the axle. This condition heightens the centre of gravity and when the load is bulky the weight is not equalized. There is apparently no unanimity of opinion as to the best form of body to be adapted to certain work. In fact, it would seem that there is as much variance in design as there is in any other mechanical construction.



Perhaps one of the most noticeable facts impressed upon the visitor to the show was the difference in the proportions of load with reference to the front and rear axles. The range for the front axle is from five to 35 per cent. and from 65 to 95 for the rear axle, this applying, of course, to the trucks, and especially to the largest types. With the lighter vehicles the proportions are much more uniform and it may be said that the variance is about 15 per cent. from 65 to 80. The wagons with capacities from 700 to 1600 pounds were often fitted with open bodies, it apparently being an assumption by the makers that these could be enclosed at will by the buyers, but it would appear that this is a condition that has not been as carefully considered as it should.

During the winter months the power vehicle must be driven through snow and slush, there being no substitute for it as the sleigh is occasionally utilized in the place of the wagon or truck, and for that reason it is desirable that it have such enclosure as will protect the freight, especially if the service be delivery. This protection is necessary during storms and against heat and dust, and there is need of sufficient carrying space to take a capacity load should the freight be bulky. This means that a single type of covered body will not serve all requirements and it is just as necessary to adapt the light vehicle to a service as to adapt a heavy machine. There is no reason to believe that a standard body installation will serve the maker as an identification of a vehicle. Should there be such supposition it is reasonable to assume that this will be a handicap to marketing instead of a stimulus. Taken as a whole there was not the improvement made in vehicle bodies as in the chassis. This is probably due to the fact that the makers of the wagons have not a realization of the extreme variation in requirements, and to inexperience with demands that will be made upon them with the increased use.

The Clark Truck.

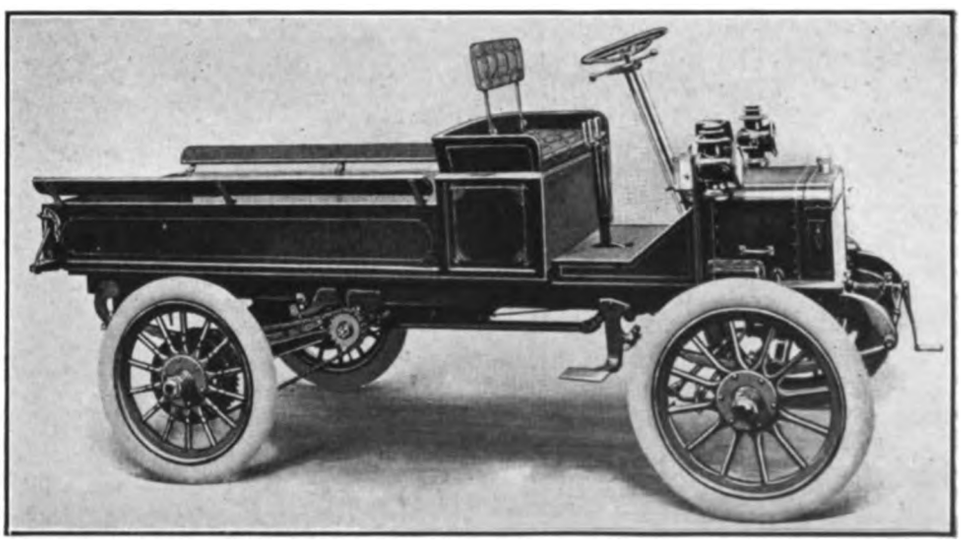


A truck that attracted much attention was the Clark, built in Boston by Edward S. Clark, who has been for years identified with the industry, but until the past two years principally by specialized steam pleasure cars, of which he produced a limited number. Last year Mr. Clark exhibited a power wagon with a two-cycle engine as a power plant. This design he has given over and is now building two types, one of three and the other of five tons capacity. The machine shown was the three-ton model, and there was also displayed the front and rear axles, jackshaft and radius rods of the larger truck.

The Clark truck is noticeable from the fact that it combines every desirable quality that long experience could

The Koehler Wagon Chassis Equipped with an Open Express Body, This Having a Capacity of 1600 Pounds.

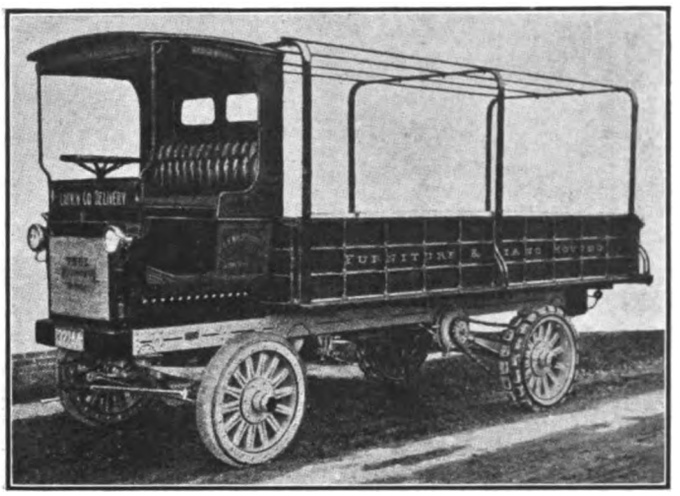
Digitized by Google



The Poss Delivery Wagon Chassis with Friction Drive and an En Bloc Motor of 25 Horsepower.

suggest, and the design's purpose was to insure service and endurance with economy of time of the vehicle and the driver in the attention necessary to insure maintenance and upkeep. The motor is mounted in a sub-frame and so low that the footboards of the driver's cab are well above it, so that there is abundant light and space for one to work on the engine under any circumstances. The motor is unusually clear of fittings and for the ordinary adjustments and attention it is not necessary to remove wiring, levers, linkage or any of the obstructions that might be expected. The steering, brake and transmission connections are installed at either side and above the motor so these may be easily reached and be out of the way of any one working on the power plant.

The motor cylinders are cast en bloc with bore of 4.125 inches and stroke of 5.25 inches, the engine being rated at 35 horsepower. The casting is carefully finished and very careful workmanship is noticeable throughout the assembly. The water jackets are liberal in size and the water is circulated by a large centrifugal pump, the cooling being by a large vertical tube radiator and a fan mounted forward of the engine, driven by a flat belt. To insure complete lubrication two gear driven plunger pumps operated by the camshaft are used. The oil is carried in a reservoir in the base of the engine case and from this the lubricant is drawn through filters and circulated through a system of tubes to a sight feed on the dash and thence the main bearings are flooded whenever the motor is in operation. There is a level of lubricant maintained in the engine case and the other moving parts of the motor are lubricated by splash. The ignition is a dual system using the Bosch high-tension magneto, the wiring being especially well protected from wear and saturation by water or lubricants. The carburetion of fuel is by a float feed carburetor with a water jacket to insure uniformity of mixture.



The clutch is a cone type engaging with the flywheel and under the leather facing flat springs are installed to prevent harsh or sudden engagement. The drive is by shaft to a Timken rear driving system, through a large jackshaft and double side chains to a dead rear axle. The transmission gearset is a selective type with three forward speeds and reverse, it being fitted with Timken adjustable roller bearings throughout. The jackshaft is equipped with a locking device by which the differential may be locked and the rear wheels driven as a unit in the event of unequal traction. This lock is operated by a handle at the left side of the chassis frame. On the jackshaft is the service brake operating on drums 12 inches in diameter and 2.25 inches width, being actuated by a pedal. The emergency brake is by expanding shoes within drums 18 inches diameter on the rear wheels, operated by a hand lever that may be set by a pawl and notched quadrant. The frame is six-inch rolled steel channel section, 42 inches width and length proportionate to the body. The standard wheelbases are 120 and 130 inches. The tread is 68 inches. The frame is built with heavy cross members and is strongly braced. It is mounted on semi-elliptic springs 42 inches length forward and 52 inches length rear, three inches width. The rear suspension is supplemented by a heavy cross spring that strengthens the action proportionate to the load carried. The front axle is a drop forged steel I section and the rear axle is a rectangular steel forging 2.25 by 3.625 inches. The wheels are 36 inches diameter, mounted on Timken roller bearings, with 36 by five-inch solid shoes forward and 36 by four-inch dual at the rear.

The control is by a vertical steering column located at the left side, pedals operating the clutch and service brake, hand levers at the centre that actuate the speed changes and the emergency brake, and hand levers on the steering wheel controlling the throttle and the ignition. As regularly geared the truck has 12 miles an hour maximum speed. The manner in which the chassis frame is mounted on the forward springs, there being a short and heavy spring horn, the installation of the radiator on helical springs carried in substantial tubing to eliminate the vibration of the truck on rough roads, the grease cups on every wearing part of the chassis, the location of the 20 gallons capacity gasoline tank under the driver's seat, the jointed starting crank,

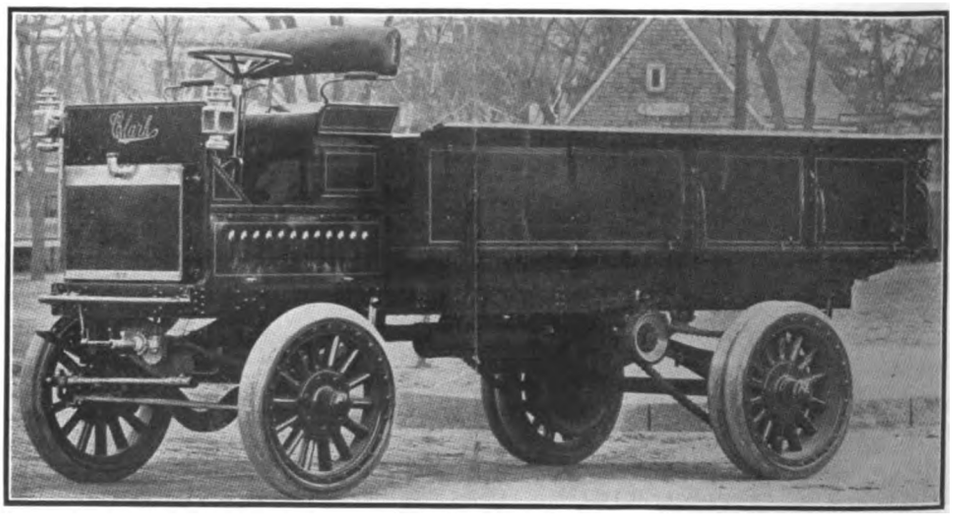
Digitized by Google

The Teel-Woodworth Truck of Three Tons Capacity, Which Has Fixed Spark and Foot Accelerator Control.

the heavy tube bumper to protect the radiator and the lamps, the strength of the steering connections and the tiebar, indicate a studied attention to design detail that appeals to the mechanical mind.

Eckhard Six-Cylinder Model.

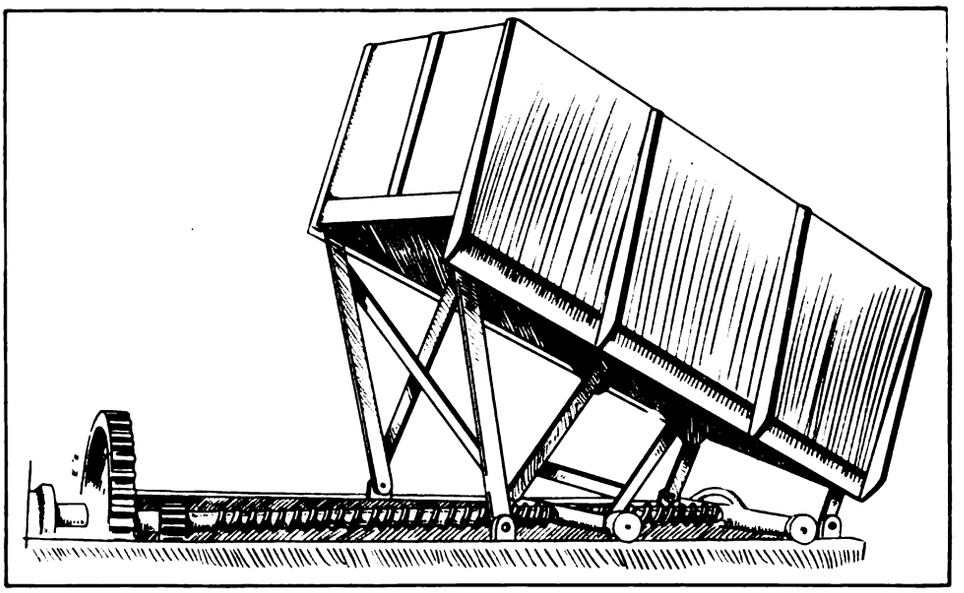
What may be regarded as the novelty of the show was the Eckhard five-ton truck, another Boston production, made by the Hercules Motor Truck Company, which was fitted with a six-cylinder motor of highly commendable design and finely finished. It is rare indeed to find a pleasure car engine that has been as carefully built, the workmanship being such as to attract the attention of every engineer and mechanic. It was exhibited as the result of 12 years' experience and experiment, and the features, aside from the motor, are the double clutch, the interlocking device, the torsion bar, the torsion chain, and the governor. It is the design of John Eckhard and there is in every detail the evidence of the care to construct what will yield service and endure under extreme conditions.



The engine is of the valve-in-the-head type with the cylinders cast in pairs, having bore of 4.5 inches and stroke of five inches. The horsepower rating by the S. A. E. standard is 48.6, but the maximum service speed permitted is 900 revolutions, at which, by brake test, 54 horsepower has been developed. In the engine every element has been designed with a view of securing the height of accessibility, and there is no operation or work necessary under ordinary conditions that cannot be performed with extreme ease. To illustrate, the valves are operated by pushrods lifted by a camshaft at the right side. The valves are all installed in separate cages and each pair of cages is retained by a yoke which may be removed by turning off a single nut, this permitting the cages to be taken out. The cams are large and the pushrod lifts are in the form of square sleeves fitted into steel guides, the sleeves carrying large hardened steel rollers, this minimizing the wear. These guides are yoke retained and can be lifted out by the removal of a yoke retained by a single nut.

The rocker arms are of splendidly finished bronze and they are pivoted on hardened steel pins of large size, the bearings being lubricated by oil ducts drilled in the rocker arms which are supplied from individual oil wells. Should it be necessary the main bearings, connecting rod bearings, and the interior of the engine may be reached by removing a cover plate extending the length of the crankcase, at the left side, while three large hand holes afford access as desired at the other side of the case. The single camshaft drives a series of bevel gears and in turn actuates the water pump, the oil pump, the magneto and the governor. The gears are encased by a bronze housing that may be readily removed and an extension of this protects the governor, which is of the ball type. The crankcase is of aluminum.

The cooling system is unusual, having very large water capacity and generous water spaces, the jackets being designed to secure rapid circulation. The water pump is of correspondingly large capacity and is installed in a bronze housing. The radiator is bolted to the main frame, its construction being such that it is not subject to damage from vibration. The top and bottom sections are bronze castings and copper tubes with large flanges for radiation are swaged into them, being expanded in the holes as are steam boiler tubes. The tubes are very heavy and are numerous, the flanges greatly increasing the radiating surface. The tubes are protected by an iron screen installed before them on the radiator frame, this being carried upward to support the forward end of the cab roof. The engine is further cooled by a large blower with bucket shaped blades that causes a circulation through the radiator.



The engine lubrication is by a gear driven pump that circulates a supply of oil through a system of tubes and a sight feed on the dash direct to all bearings and to each cylinder, and by splash, there being a constant level maintained in the base of the engine case. The fuel is vaporized in an automatic float-feed carburetor, this being water jacketed to afford a constant quality of gas. The ignition is by two independent systems and 12 spark plugs, using the Bosch high-tension magneto for the one, or the storage battery, transformer coil and timer for the other. These two systems may be used simultaneously if desired.

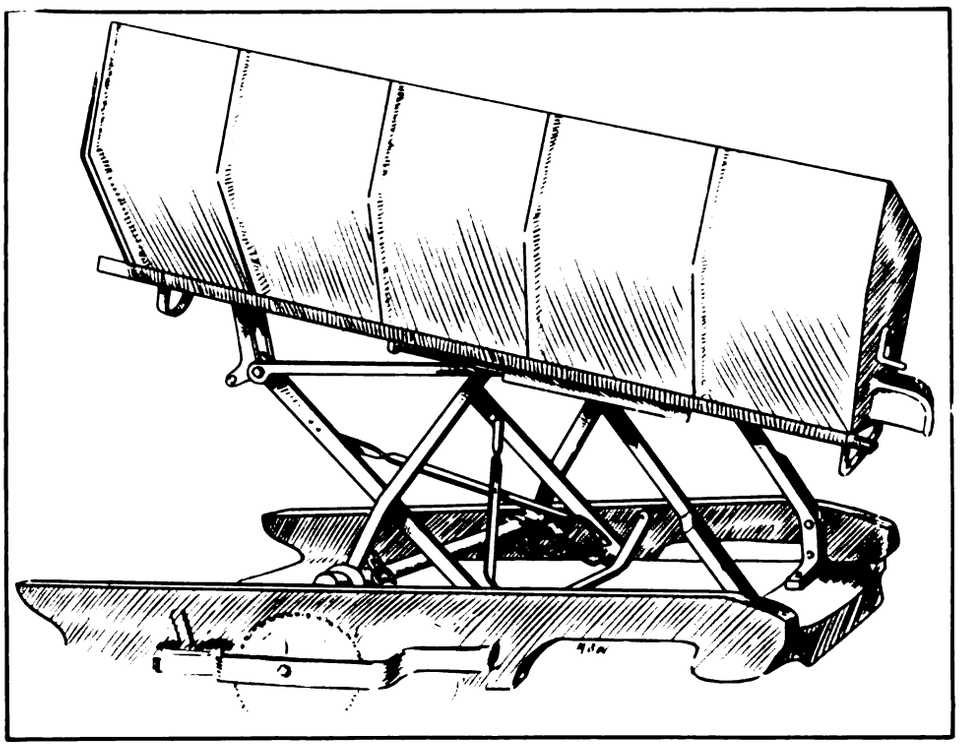
The motor is installed in a sub-frame that is mounted at the forward end on the heavy chassis frame. The rear of the sub-frame is supported at either side by swivelled links from a wide yoke that is pivoted on a frame cross member. The driving system is unique in that there is between the motor and the differential two cone clutches. These clutches are very large and both are of the reverse type. Between the forward clutch and transmission is a universal joint and the connection with the mainshaft of the transmission is flexible. The transmission is very large

Clark Three-Ton Chassis, 35 Horsepower, with En Bloc Engine, Fitted with a Furniture Body.

Digitized by Google

Steel Lined Wood Coal Body with End Discharge, Elevated by Horizontal Worm and Gear Hoist Operated from the Driver's Seat, Installed on a Peerless Chassis.

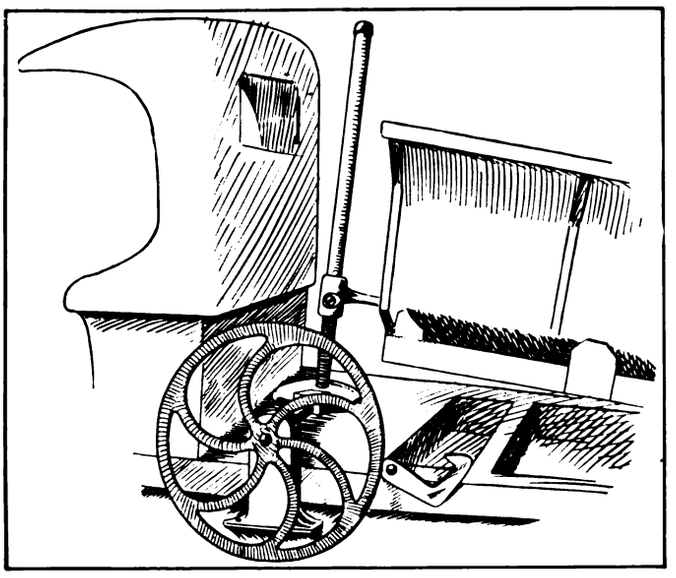
and the shafts and gears are nearly double the size of those designed for vehicles of this class. Between the differential and the extension of the main transmission shaft is a second clutch. There is an interlocking system by which when the clutches are disengaged the transmission shaft is brought to an instant stop by a brake and change of speed can only be made when the transmission gears are not moving. The vehicle may move ahead by its momentum but the gears cannot clash nor can they be stripped. The teeth are rounded so that engagement may be made under any condition.



The transmission case is carried in a sub-frame, the forward end of which is suspended by swivelled links from the arms of a yoke pivoted to the heavy frame cross member, exactly as is the motor sub-frame. The rear end is suspended from a cross member behind the jackshaft. There are no stresses upon the driving system and it is maintained that under no circumstances will frame distortion have any effect upon the shafts and transmission, while the alignment will always be preserved by the radius rods. The drive from the jackshaft is by double side chains. The frame is mounted on semi-elliptic springs and these are supplemented by patented helical springs interposed between the axles and frame, these taking the load and reducing the stress upon the main springs in proportion to the needs.

Extending from the centre of the rear axle to the centre of the front axle is a long rod that is fitted with a heavy spring buffer at the forward end. The function of this device is to carry the drive of the rear wheels to the forward axle, to distribute the road shocks on the front wheels to the rear construction, and to prevent unequal movement of the axles. In this respect it serves as a distance rod and has precisely the same effect as has the perches of the animal wagon. To prevent the turning movement of the rear axle resulting from driving and braking action a torsion chain is used, this being attached to the centre of the rear cross member of the frame and extended to the end of a stout arm mounted on the centre of the rear axle and rising to a sufficient height to afford full leverage. The entire construction is with a view to minimizing the strain that might result from work under extraordinary conditions, as from striking obstructions of any kind.

The frame is of heavy steel channel section, strongly reinforced and hot riveted. The wheels are 40 inches diameter and the tires are six inches, single forward, and five inches, dual, rear. The wheelbase is 144 inches. The control is by a pinion and gear connection and a vertical steering column, with ignition and throttle lever mounted above the steering wheel, by clutch and service brake pedals, by foot accelerator, and by speed change and emergency brake levers at the right of the driver's seat. The service brake is with contracting bands operating on brake drums on the jackshaft, and the emergency brake is with shoes expanding within drums on the rear wheels. Both brakes are very large and efficient. As a further protection there is a double sprag of heavy construction that may be dropped at will by a hand lever at the driver's seat. The capacity of the gasoline tank is 22 gallons, there being a reserve tank containing two gallons that may be drawn upon when the main supply is exhausted.



Bessemer Delivery Wagon.

The Bessemer delivery wagon, produced by the Bessemer Motor Truck Company, Grove City, Penn., was the only ve-

Steel Coal Body with Chute Discharge at the Rear, Elevated by Power Hoist, Capacity Five Tons, Mounted on an Alco 3.5-Ton Chassis.

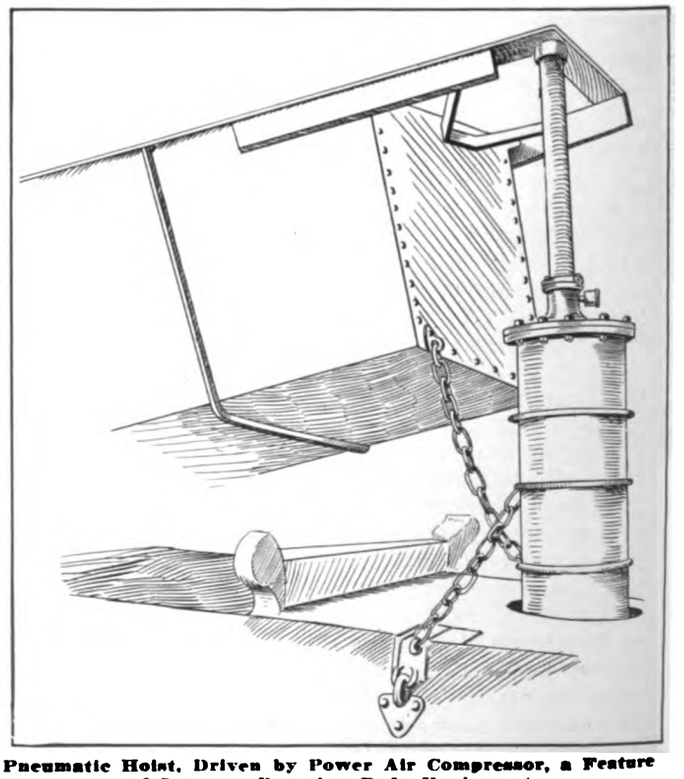
Worm and Nut Hand Hoist as Fitted for Use on a Pierce-Arrow Five-Ton Worm-Driven Truck.

hicle designed for purely industrial purposes that was shown with a self-starting device. This machine was noticeable for the strength and simplicity of its construction, it being maintained by the maker that it has every quality that makes for long endurance with heavy service. The capacity is one ton. But one type of chassis is built, this being with wheelbase of 107 inches. The four-cylinder motor is of en bloc construction with bore of 3.75 inches and stroke of 5.25 inches, which has an S. A. E. horsepower rating of 22.5, and is conservatively rated at 25 horsepower by the maker. The motor is water-cooled and the water is circulated by a centrifugal pump. The radiator is large and is supported by springs to eliminate vibration stresses. The lubrication is by mechanical force feed to the main engine bearings and splash. The ignition is by the Bosch dual system with high-tension magneto. The carburetor is a float feed type, automatic in action, supplying a constant mixture.

The clutch is a cone with cork inserts, having 110 square inches of frictional surface, insuring against harsh engagement or slipping, being always positive in its action. The transmission is a selective type with three forward speeds and reverse, with nickel steel gears and shafts, the gears having .9375 inch face. The drive is jackshaft and double side chains to a dead rear axle. The chassis frame is a pressed steel channel section and is strongly reinforced. It is carried on semi-elliptic springs forward, 39.5 inches length and 2.25 inches width, and platform suspension at the rear with springs 45.25 inches length and 2.25 inches width. The front axle is a nickel steel I section with spindles 1.6875 inches diameter, and the rear axle is of the same material with spindles 1.9375 inches diameter. The wheels are 34 inches diameter, with 14 spokes, the forward tires being 34 by three inches and the rear tires 34 by 3.5 inches. The control is by a steering column at the left side, with clutch and service brake pedals and speed changing and emergency brake levers in the centre. The brakes are external contracting and internal expanding with 14-inch brake drums on the rear wheels. The turning radius of the wagon is 33 feet, especially adapting it for service in congested traffic.



The New Chalmers.

The Chalmers light delivery wagon chassis is a model M pleasure car construction with adaptations that strengthen it for continuous service. The chassis frame is straight and longer and the springs are heavier, and the speed is reduced by gearing the motor four to one. The wheels are fitted with 34 by 5.5-inch pneumatic tires. The capacity is 1000 pounds. It is furnished with three types of body, an open express, or with enclosed body with curtains or panel sides. The open body has a load space 46.5 by 72 inches, and the close bodies have the same area with a height of 60 inches. The maker is the Chalmers Motor Company, Detroit.

Couple-Gear Vehicles.

Exhibited for the first time in the East were the Couple-Gear contractor's wagons made by the Couple-Gear Freight-Wheel Company, Grand Rapids, Mich., these being designed especially for haulage of heavy loads under conditions where ordinary power vehicles could not be used advantageously. Two were shown, the one being a Philadelphia dump cart and the other a bottom-dumping wagon. With these the wagon bodies are mounted on heavy dead axles and large wheels, these being fitted with steel tires. The wagon frame is extended forward of the bodies and the front wheels are replaced by the motor driven disc wheels peculiar to the Couple-Gear vehicles. In brief to the heavy wheel spindles are fitted electric motors each having a normal capacity of three horsepower. The armature shaft of the motor extends to the periphery of the discs forming the wheel, pinions at either end of the shaft meshing with racks integral with the discs. Outside of the discs is placed the wheel rim and the tire.

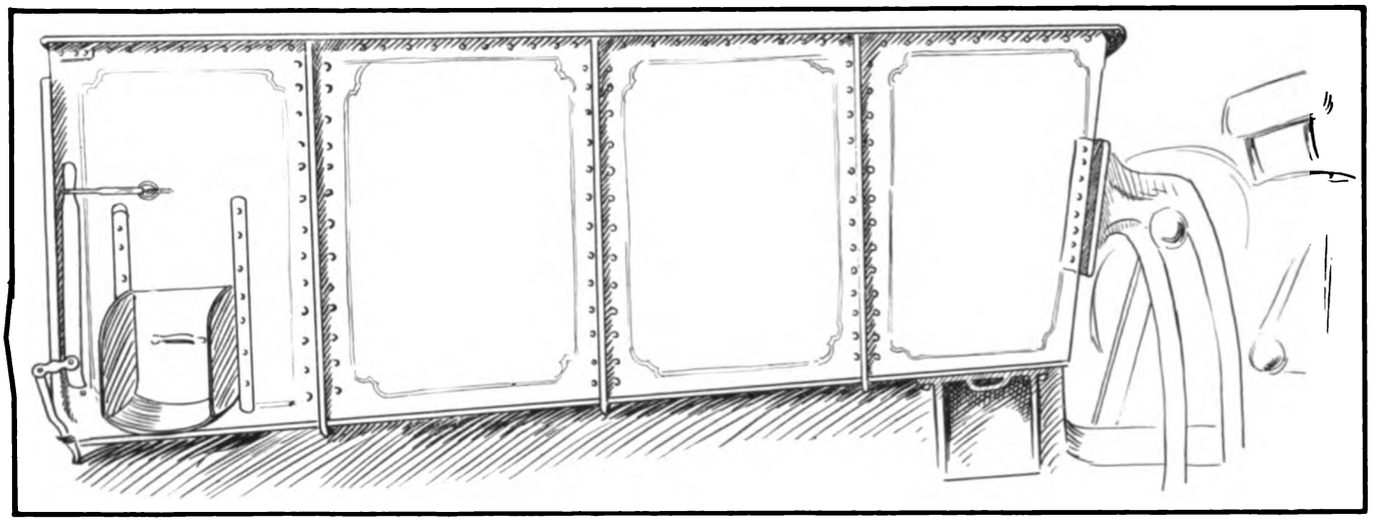
The energy is supplied by a battery carried under the seat of the driver. The control is by a lever, as is the electric street car, giving five forward speeds and five reverse speeds. As the motor revolves the pinions at the ends of the shaft turn in the racks and cause the wheels to revolve. As the pinions have nine teeth and the racks 240 it will be seen the reduction is 26.66 to one, this permitting the utilization of the power slowly and with an efficiency that is claimed to be 97 per cent. With this form of vehicle it is maintained that the pulling capacity of the motor is greater than its pulling power, that these wheels permit the use of standard wagon construction, that the large rear wheels minimize the tractive effort, can be drawn over road obstructions readily, reduce the vibration and can be used with better results in soft ground.

Pneumatic Hoist, Driven by Power Air Compressor, a Feature of Sampson Dumping Body Equipment.

Digitized by Google

Steering the driving wheels always causes the tractive effort to be in the direction in which the vehicle is moving. The construction is not designed for speed, but for continuous work. About 90 per cent. of the load is carried on the steel tires. These carts are built with capacity from one to five tons. The same company builds all manner of trucks driven by four wheels, either by battery, or by battery that is constantly charged by a gasoline motor operated on the truck. It also builds tractors with gas-electric power plants that are fitted to draw loads carried on two large wheels with steel tires, these being another adaptation of the same principle of loading as has been described for the dumping wagons. The trucks are constructed to six tons capacity.

The control of these wagons is such that they can be handled by one not possessed of mechanical knowledge, the main requirement being judgment of speed and distance. As the load speed is about five miles an hour, and the maximum pace about seven it will be seen that speed is not an element of danger. Instead of the usual volt-ammeter is fitted the Sangamo ampere-hour meter which indicates zero on a dial with amperes as the scale unit when the battery is fully charged. As the battery is drawn upon the meter shows the exact energy remaining in the battery in amperes, and so at any time the condition of the power is shown. It is possible to reduce the battery to the capacity. The indication is not changed until the battery is charged when the dial will show the process of charging as it did discharging, and when the charging is complete the circuit is automatically cut off, so that the only operation necessary in storing the battery is to make the connection and leave the wagon.



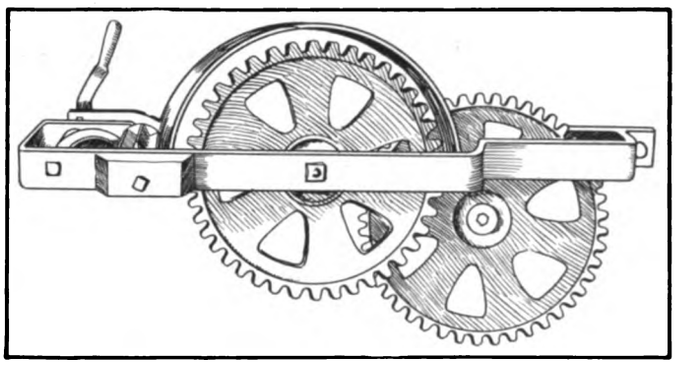
The wheels are accessible by hand holes in the outer discs so that the axle spindles, the bearings, the motor, the shaft, pinions and rack are convenient for examination or work. There is no other mechanism save the steering linkage and the steering column, and the driver has but comparatively little labor to perform. So far as simplicity and durability are concerned it is maintained that these vehicles may be used without regard to the ordinary attention given to motor driven vehicles.

The display was wholly for the benefit of those engaging in heavy haulage and was with regard only for those who have to do with a character of service for which the horses are even now considered to be best suited. It is possible, however, to employ these wagons for excavating and similar work. Incidentally the motors are of three horsepower each, making a total of six for the vehicle, but as these are capable of yielding an overload capacity of 300 per cent. for a limited period it will be understood that this equals 18 horsepower whenever that energy is needed.

Teel-Woodworth Display.

The Teel-Woodworth truck of three tons capacity was shown for the first time at a national exhibition and attracted much attention because of the practicality of the design and the substantial construction. The truck is built by the Teel Manufacturing Company, Medford, Mass., a firm that has produced animal vehicles for nearly a century, and which has in recent years devoted some of its activities to producing high grade automobile equipment. The company is widely known to the automobile industry, but only recently has it engaged in motor vehicle construction.

In producing the truck the designer has made no experiments. To the contrary he has combined elements produced by manufacturers of reputation, there being a Continental engine, for instance, a Hele-Shaw multiple disc clutch, a Cotta transmission, a Timken jackshaft, rear and front axle and brakes, a Ross steering gear, and a Mayo radiator, these being incorporated into a vehicle that has been created to afford a maximum of everyday service, to be operated with fullest economy.



Monahan Body, Affording Forward and Rear Side and Rear Discharge, with Hand Hoist, Six Tons Capacity, Exhibited on Speedwell Chassis.

One of the objects sought was to eliminate many of the ordinary causes for delays, and to secure this every element that might be subject to derangement has been safeguarded. In other words the truck has been made as nearly fool proof as long experience would dictate was desirable or necessary. All the parts are jigged to insure perfect interchangeability, these being produced by one of the best known of the fine machine builders. All of these parts are carried in stock and may be obtained quickly. Practically all the bolts are of four sizes, standard thread, and these may be purchased in any good hardware store in the country. Every nut and bolt is cotter pinned, two sizes of pins being used, All the small pins and shafts are hardened and ground. The spring eyes are bronze bushed and should wear indefinitely, but the bushings may be replaced with slight cost. It is maintained that these qualities make for inexpensive upkeep and insure against delay.

The motor is water-cooled, with the cylinders cast in pairs, and is rated at 30 horsepower by the S. A. E. power standard. The water is circulated by a centrifugal pump and a fan driven by a belt. The radiator is of large capacity and the engine will not heat under any condition of operation. It is lubricated by a gear driven pump from a reservoir integral with the engine case that floods the

Digitized by Google

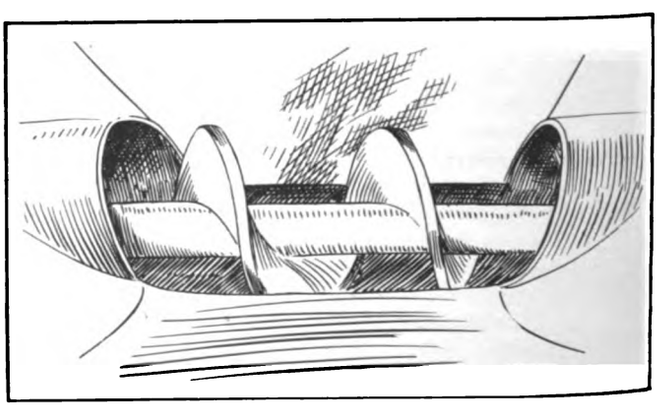
Hand Lever and Gearing of the Power Hoist as Exhibited on an Alco Five-Ton Truck with Dumping Body.

engine bearings, and by splash. The carburetor is a float feed automatic type that will deliver a uniform gas at all times. The ignition is jump spark by a Bosch high-tension magneto with fixed spark. There are but five wires, four to the spark plugs and the other to the switch, and these leads are encased to protect them against wear and saturation by lubricant or moisture. The attention to the ignition system is minimized.

The Hele-Shaw multiple disc clutch has 28 discs and these are contained in a case that retains a sufficient quantity of sperm oil so that the discs are constantly lubricated. The clutch engages without harshness and it may be slipped continuously if desired without damage. The transmission is so designed that the gears are in mesh at all times and the speed ratios are secured by the movement of dog clutches between the gears. At high speed the gears are all idle. It is impossible to strip the gears. The speeds are three forward and reverse, with a maximum of 14 miles an hour, this being limited by the governor.

The jackshaft is with shafts 1.75 inches diameter and it is mounted on Timken roller bearings, that may be adjusted for wear, and which take the end thrust. The bearings are carried in the steel housing of the jackshaft. The drive is by double side chains. The axles are heavy steel drop forgings, the wheel spindles being fitted with Timken roller bearings throughout. The wheels are 36 inches diamter, with 36 by five-inch solid tires forward and 36 by four-inch, dual, rear. The chassis frame is a heavy steel channel section, with strong reinforcements. The springs are 45 inches front and 54 inches rear, half-elliptic, with the spring bolts case hardened and fitted in bronze bushings. The wheelbase is 125 inches and the tread 63 inches.

Control is by a vertical steering wheel with clutch and service brake pedals and a foot accelerator, there being no throttle lever. Side levers operate the transmission gearset and the emergency brake. The service brake has bands contracting on drums 14 inches diameter and three inches face on jackshaft, and emergency brake has shoes that expand within the 20 inches diameter on the rear wheels. These brake shoes are faced with Non-Burn. The gasoline capacity is 20 gallons with the tank under the driver's seat, and beside this is a separate tank that will contain two gallons of oil, the contents of which may be supplied to the motor by turning a petcock. The driver's seat is covered by a standing canopy that is supported by stanchions from the back of the seat and the radiator frame. The radiator is mounted on springs to nullify vibratory influences and it is protected by installation behind the strong front frame cross member. The dash and tail lamps are lighted from a storage battery.



Koehler Delivery Wagon.

Of the delivery wagons of small capacity the Koehler machine, 1600 pounds capacity, was especially noticeable for the series of innovations, all of which had been combined with a view of obtaining extreme economy and endurance with minimum maintenance and upkeep cost. The chassis differs with present practise in that the motor is carried in a frame amidships, under the body floor, but it is accessible from the sides or by a trap in the body floor, while the position makes a very low centre of gravity, a condition of material importance in tire endurance. The purpose has been to produce a machine of low cost that would have moderate capacity and could be operated cheaply, the idea being that there was a large field for a vehicle that would be serviceable for light delivery and have such speed that it would be useful under practically all business conditions.

The engine is of the opposed type, with cylinders having bore of 5.25 inches and stroke of four inches, the power rating being 22 by the S. A. E. standard formula. The water jackets are large to secure efficient cooling under continued operation, they being cast integral with the cylinders. The cylinders are bored to size and ground and lapped to a finish. The pistons are turned, ground and lapped to size and, with the piston rings, are fitted with much care to secure complete compression. The crankcase is large and is designed with a view to obtain unusual lubrication. The engine has two main bearings, the forward one being 3.5 inches length and the rear 4.5 inches length, or a total of eight inches. The crankshaft is nickel steel, 1.875 inches diameter, with the crankpins 2.5 inches length, and a five-inch flange drop forged integral with the shaft. To this flange the flywheel is bolted. The connecting rods are of bronze, cast with a deep channel extending the length. The wristpins are of steel, ground, hardened and lapped. The camshaft is forged of tool steel, with the cams integral, and this is hardened and ground to a finish. The bearings are of the best babbitt metal throughout. The valves are 2.25 inches diameter, are mechanically adjustable and are interchangeable.

The cooling is by thermo-syphon circulation of the water through the large water jackets of the engine and the cellular radiator. Contrary to conventional practise the water inlet and outlet of the radiator are at the base, so that the heated water entering the radiator must rise through the coolest of the fluid, quickly reducing the temperature. No matter to what extent the water in the radiator may be reduced it will be circulated and cooled so long as there is a sufficient quantity to fill the water jackets and the piping system. The radiator is large and is suspended on helical springs to eliminate vibration.

The lubrication of the engine is force feed and splash in combination. There is a considerable oil reservoir in the base of the crankcase from which the oil is drawn by a gear driven pump and circulated through tubes, whence it is delivered in streams into the channels in the bronze con-

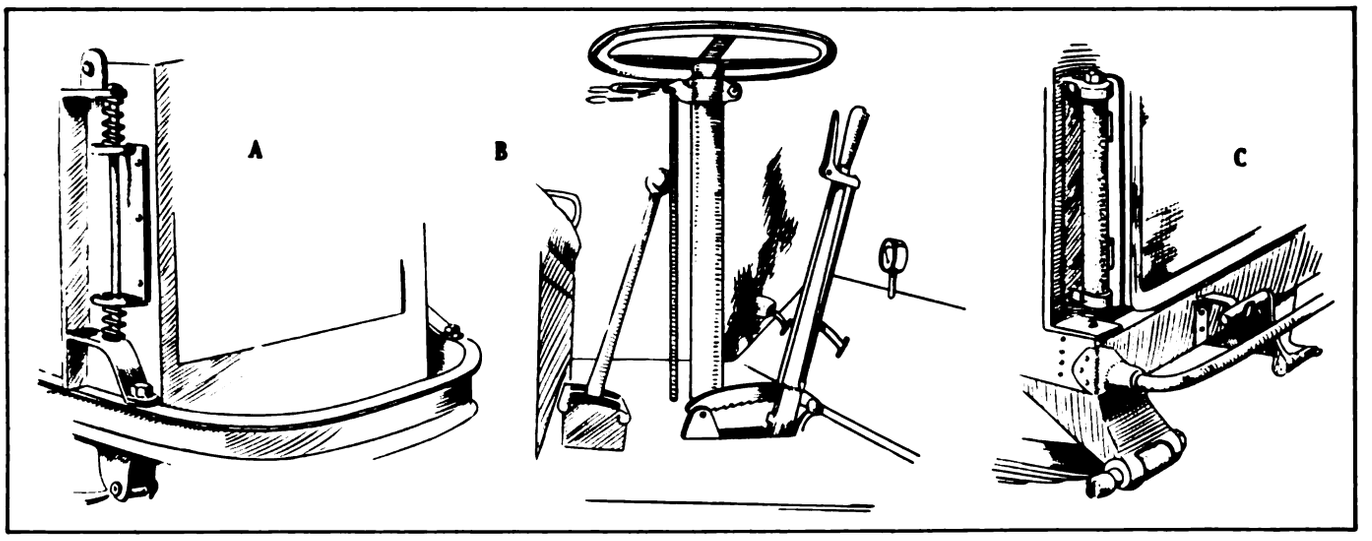
Screw Discharge of the Morgan Truck as Seen at the Bottom of the Hopper-Shaped Body, Power Being Furnished by the Motor.

Digitized by Google

necting rods, through which it is distributed to the wristpin and crankpin bearings, and to the main bearings. The camshaft bearings, cylinder and piston walls, and the timing gears, are lubricated by splash. The oil is filtered as drawn from the reservoir. The ignition is by Bosch magneto located on top of the engine case that is driven by enclosed gears. The carburetion is by a float feed automatic carburetor.

The flywheel is mounted on the flange forged on the crankshaft and the engine is installed on forged steel hangers, so that it may be dropped out of the chassis very quickly and easily. The engine shaft is extended, with a single universal joint, to a combined transmission and jackshaft that is installed transversely in the chassis. The jackshaft case is a heavy oil-tight casting in which the jackshaft is mounted on very large journals. The transmission is planetary, all gears being of hardened chrome nickel steel, the shafts of hardened special alloy steel, ground to size, with bearings of phosphor bronze in semi-steel casings. The clutch bands for the low and reverse speeds are semi-steel, which cannot slip or burn, and the high speed clutch is a cone. The entire transmission is driven in an oil bath. The drive is by double side chains to sprockets on the rear wheels. The closeness of the sprockets materially reduces the length of the chain required.

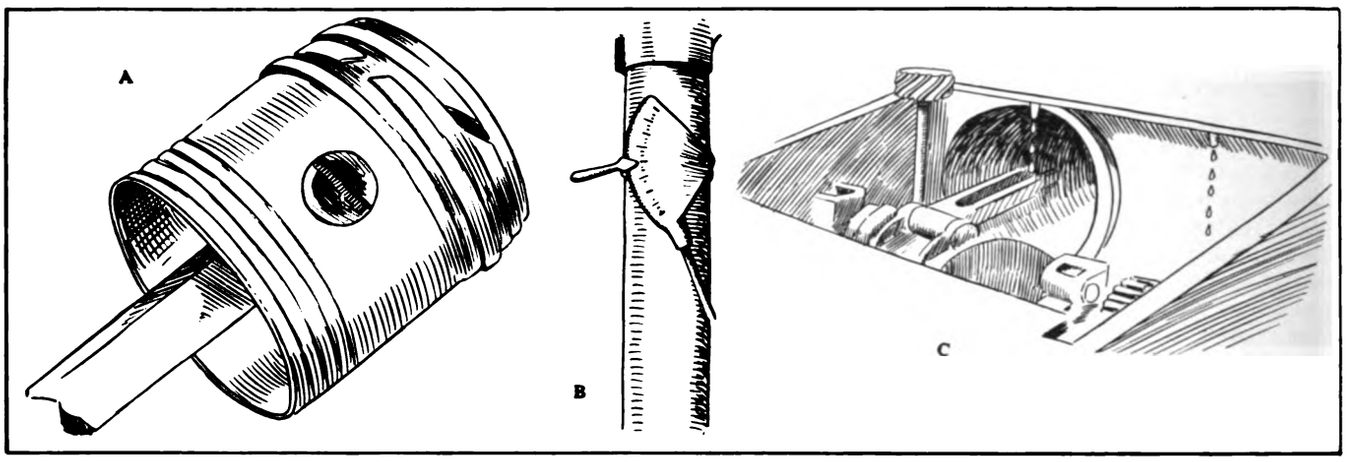
The chassis frame is U shape, with the curved end at the front, where it extends considerably beyond the radiator, forming a solid and serviceable protection against damage from contact with an obstruction. This frame is with five cross members besides the engine and the jackshaft supports, being unusually stiff and strong. It is carried on semi-elliptic springs forward and full elliptic springs at the rear. At the forward end of the chassis, directly behind the radiator, is a cast metal footboard, which is bolted to the frame. Cast integral with this footboard is the base for the vertical steering column, the brackets supporting the clutch, brake and brake pedals, and the throttle linkage. The footboard stiffens the frame and makes certain the stability of the assembly. The steering gear is of the bevel pinion and sector type with a 16-inch hand wheel.



The front axle is a single steel forging 1.5 inches square, with the knuckle yokes integral. The rear axle is two inches square, forged from steel. The service brake operates on the jackshaft with braking surface of 75 square inches, metal to metal surfaces. The emergency brake is on drums on the rear wheels. The wheels are large and are fitted with solid rubber tires, two inches width. The wheelbase is 86 inches and the tread 56 inches. The drive is at the left side and the reverse and low speeds are controlled by pedals, with high speed clutch and the emergency brake operated by a single lever at the right of the driver. The fuel tank of 16 gallons capacity and the oil tank holding a gallon are located under the driver's seat. The maximum speed is 16 miles an hour. The weight is approximately 2000 pounds. The maker is the L. E. Schlotterback Manufacturing Company, Newark, N. J., for the H. J. Koehler Sporting Goods Company, New York City.

Poss Designed by Renault.

The Poss motor wagon, made by the Poss Motor Company, Detroit, was designed by Louis F. Renault, a French engineer of large experience, and it has in the engine a combination of qualities that are claimed to afford unusual power and longevity. The vehicle is friction driven, and simplicity and accessibility are features impressed upon the observer. The motor has four cylinders, cast en bloc, with bore of 3.5 inches and stroke of 4.75 inches, and is claimed to deliver 25 horsepower with 1200 revolutions. The water jackets are largest at the top and, with the exhaust manifold, are cast integral. The water intake is 2.5 inches diameter. The fuel header is integral with the block so that the incoming gas is heated by contact with the heated walls and carburetion is perfected. The water outlet manifold extends the length of the top of the cylinder block and has a main outlet with a Y with outlets 1.75 inches diameter. The manifold is attached to the block by four studs .375 inch diameter. The studs are threaded into plugs that are in turn threaded into the block, gaskets insuring a perfectly tight fit. The fuel manifold is unusually direct and fuel is uniformly fed to the cylinders.



The engine block is cast from gray iron, and being of the T type the valves are at the right side. After boring the block is aged and then reamed and ground to size. The pistons are of the same material and are similarly treated in the making. They are fitted with three .25 inch rings above the wristpin and an oil ring near the base. Below the oil ring is an oil groove that is drilled at intervals of 60 degrees, through which oil collected by the ring is drained through the piston walls into the engine case. The engine case is a barrel shaped casting with the front web and the oil reservoir integral, there being a bottom plate that may be removed to afford access to the connecting rod bearings.

The crankshaft is a two-bearing type with bearings two inches diameter, the forward bearing being three inches length and the rear bearing four inches The shaft is of

carbon steel, double heat-treated to insure strength. The crankpin bearings are .9375 inch diameter and 1.625 inches length. The bearings are the best grade of nickel babbitt. The timing gear is keyed to the crankshaft. The forward main bearing is pressed and pinned into the forward web of the crankcase, and the rear bearing is pressed into a removable plate fastened with eight .5-inch cap screws. The crankshaft is offset .375 inch.

Perfect alignment is obtained by the method of installing the bearings. Plates eight by 10 inches at the bottom of the crankcase permit work on or examination of the main engine bearings. The camshaft is a carbon steel forging with the cams integral and the three bearings are 1.75 inches diameter and the forward bearing, flanged to receive the timing gear, is three inches in length. The centre and rear bearings are one and 1.4375 inches length, respectively. The bearings are phosphor bronze and are adjustable for end play by a hardened steel washer and an adjusting lock nut. The cams have a .3125-inch lift. The camshaft timing gear is attached to a 2.875-inch flange by four .375-inch bolts, wired to prevent slackening.

The valves are 1.75 inches diameter, with cast iron heads electrically welded to stems .4375 inch diameter, six inches length and hardened at the ends. These operate in guides 2.625 inches length. The stems are slotted to receive the key retaining the large springs. The tappet rods are of tool steel, hardened and ground, 1.375 inches diameter wearing face, the upper end tapped for an adjusting screw into the head of which is inserted a gray fibre disc to eliminate noise. The rods are operated in .75-inch bronze bushings, with oil grooves to prevent lubricant working out above the bushings. The connecting rods are I section drop forgings, 9.5 inches from centre to centre, with oil holes drilled to the crankpin bearings. The crankshaft is removable from the rear of the case, the camshaft from the front. The timing gears are steel for the crankshaft, and iron for the camshaft and the magneto driving shaft, having inch faces. These are housed by a cover attached to the forward web of the case.

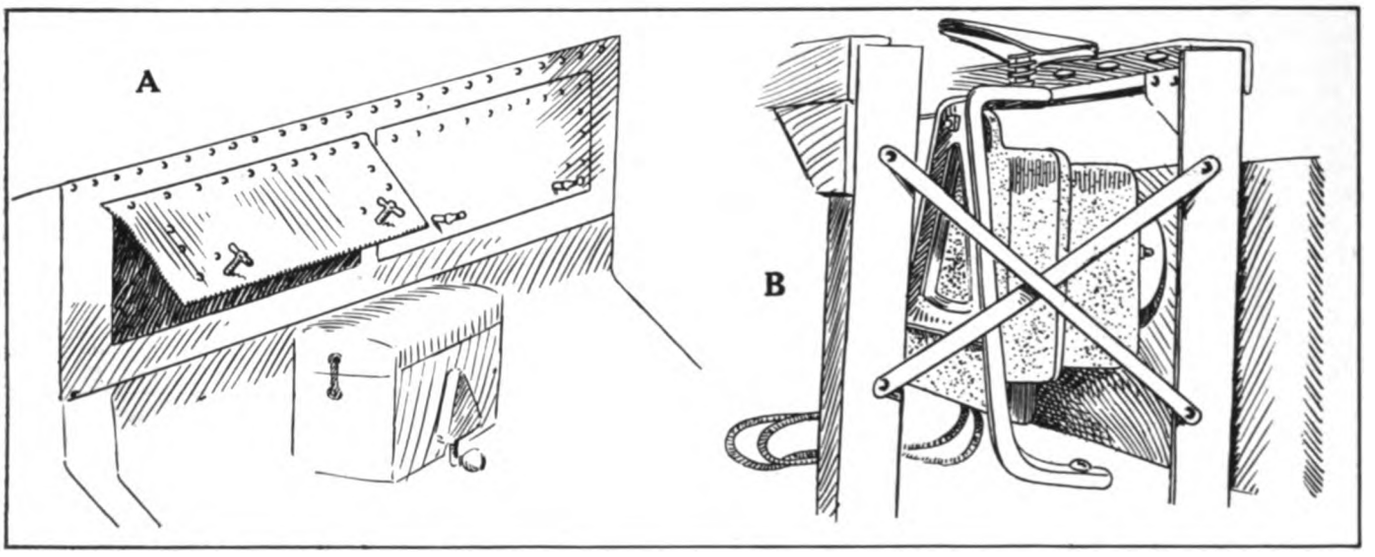
Lubrication is by splash from a constant level in the base of the engine case, large pockets supplying the crankshaft and camshaft bearings, the oil level being automatically maintained by feed from a reservoir cast integral with the crankcase. The cooling is by thermo-syphon circulation of water through the water jackets and the radiator, radiation being promoted by a fan driven from a pulley mounted on an extension of the crankshaft. Ignition is by a high-tension magneto with a fixed spark, the magneto being carried on a bracket cast integral with the engine case. The carburetion is by an automatic float feed carburetor. As there is a minimum of wiring and as the valve stems and tappets are enclosed by plates that are removable by winged nuts, the engine is unusually simple and clear.

On the crankshaft is installed the flywheel and bolted to the flywheel is a heavy steel arm. Behind this arm is a large clutch spring. This spring contacts with a flange fixed to the forward end of the driving shaft. This shaft is mounted in a large bearing carried on a heavy cross member, and on the rear end of the shaft is the driving disc, heavily webbed, 17.5 inches diameter. Between the flywheel and the rear shaft bearing is a universal joint. The cross member of the frame is strongly braced. Back of this cross

Spring and Torsion Rod Details: A, Stearns Forward Spring Horn; B, Velie Radius Rod and Adjustments; C, Stearns Provisions for Radius Rod Adjusting; D, Forward Shackle of Velie Rear Spring.

Digitized by Google

member, and ahead of a second cross member, is the jackshaft, carried in heavy bearings. On this jackshaft is the driven wheel with a fibre face, that is moved transversely to any position, affording all the ratios of speed peculiar to roller or friction transmission. The drive from the jackshaft to the rear axle, which is of the semi-floating type, is by a single chain. The rear axle is 1.375 inches diameter and is housed by a tube 2.75 inches diameter, the differential assembly carrying the sprocket. The axle is supported by two truss rods, .4375 inch diameter and the axle relation is maintained by two steel radius rods .75 inch diameter, anchored to the rear spring saddles.



The chassis frame is a pressed steel channel section 135 inches length and with the two cast steel motor supports there are seven cross members, with triangular gussets at the rear end. The springs are semi-elliptic, the forward set being 36 inches length and 1.75 inches width, six leaves, perched off centre, with 20 inches spring length behind the axle centre. The rear springs are 45 inches length and two inches width, of nine leaves, shackled front and rear to eliminate driving stress. The front axle is a steel tube two inches diameter with drop forged nickel steel knuckles electrically welded to it. With pneumatic tires the wheel diameter is 34 inches, with tires 34 by 3.5 inches, and with solid tires the wheels are 36 inches diameter, with tires 36 by 2.5 inches.

The control is from the right side by an irreversible steering gear of the worm and split nut type, with a 16-inch wheel. The tiebar is before the front axle and is .75 inch diameter. The clutch is operated by a pedal and the service brake also is actuated by a pedal, the shoes of the internal expanding type being within drums on the rear wheels 12 inches diameter and 2.5 inches face. This brake is equalized. The speed is changed by a hand lever. There is a throttle hand lever on the top of the steering column. The wheelbase is 96 inches and the tread 56 inches. The capacity of the wagon is 1000 pounds. Under ordinary conditions three types of bodies are furnished with this chassis.

Mercury Delivery Wagon.

The Mercury delivery wagons, made by the Mercury Manufacturing Company, Chicago, Ill., are of 1000 pounds capacity. These are a type intended for hard service and to be operated with economy. The engine is with two cylinders opposed, mounted horizontally at the forward end of the chassis. The cylinders are cast with the radiating flanges integral, having a bore of 4.25 inches and stroke of four inches. The offset of the cylinders is 2.125 inches. The rating is 15 horsepower by the S. A. E. standard. The radiating surface of the motor is unusually large. The camshaft is mounted directly above the crankshaft, the cams being very large and contacting with large flanges on the ends of the valve pushrods. The valve stem guides are large and long, and instead of the usual helical spring the valves are operated by heavy springs with a single coil and ends spreading between the guides and the keys in the slotted valve stems. This removes the springs so far from the heat of the cylinders they are not affected. The crankshaft and camshaft are large in size with generous bearings, and the connecting rods are ample in proportions. The ignition is by a storage battery and dry cell battery, coil and timers.

The engine is lubricated by mechanical force feed to the main and connecting rod bearings, and by splash to the camshaft, camshaft bearings, timing gears, valve pushrods, wristpins, cylinders and pistons. The radiation is by a forced draft of air caused by the fan blades of the flywheel. The carburetor is a float feed instrument made by the Mercury company. The transmission case is bolted to the engine case, this making a unit power plant. The gearset is planetary, with disc clutch, all clutches and direct drive being secured through the use of a single lever, giving two forward speeds and reverse. The drive shaft is carried, with a single universal joint, through a stout torsion tube to the jackshaft and differential assembly. The jackshaft housing is large and there are liberal bearings. The drive is by double side chains to sprockets on rear wheels, mounted on a dead axle.

Convenience and Protection Considered: A, Tool Box Located in the Top of the Dash of Dayton Trucks; B, Suspension of the Ammeter in the Walker Delivery Wagon, Permitting Instant Removal.

The construction is such that the motor may be easily removed for work. The moving parts are encased and are operated in oil baths, being thoroughly protected from road accumulations. The chassis frame is of armored wood and is strongly reinforced. It is suspended on full elliptic springs, forward and rear. There are two sets of brakes, with internal expanding shoes faced with Thermoid, operated within drums on the rear wheels. The wheels are artillery type, 38 inches diameter front, and 40 inches diameter rear, with 1.75-inch solid tires on standard rims. The wheelbase is 85 inches and the tread 56 inches. The single lever operates the transmission, and the service and emergency brakes are actuated by foot pedals. The steering column is tilting and is located at the right side.

New Mora Design.

The Mora delivery wagon, made by the Mora Power Wagon Company, Cleveland, O., has 1500 pounds capacity. It has a horizontal opposed motor with bore and stroke of 4.5 inches, the cylinders being cast with the large water

Digitized by Google

jackets integral. The rating by the S. A. E. standard is 16 horsepower. The water is circulated through large hose connections and an ample radiator by thermo-syphon movement of the fluid. The radiator is of the square tube type, and a draft of air is forced through it by the movement of the fan-bladed flywheel. The ignition is by a low-tension magneto and transformer coil, with a dry cell battery for starting and reserve. The lubrication is by mechanical force feed and splash, affording a liberal supply of oil under all conditions of operation. The mechanical oiler is operated by an eccentric on the camshaft and is located on the dash in sight of the driver. The carburetor is a float feed type, automatic in its action.

The driving system is carried through a mainshaft, with two universal joints, and to the transmission, which is located just forward of and bolted to the jackshaft housing. The assembly is such that the clutch, transmission and jackshaft are practically a unit. The transmission is a planetary type with the high speed clutch of steel discs. The gears and clutch operate in a bath of oil. In the jackshaft the differential is mounted on annular ball bearings, with outer ends being carried on large roller bearings. The drive to the rear axle is by double side chains. The chassis frame is of pressed steel channel section with six cross members. It is strongly braced and reinforced. This is carried on semi-elliptic springs. The chains are adjustable by the I section distance rods. The axles are special steel forgings, 1.5 inches square. The wheels are 36 inches diameter, with tires 36 by two inches forward and 36 by 2.5 inches rear.

The control is by an irreversible steering wheel located at the left side. The control is by pedals operating the low and reverse speeds and the service brake, and hand levers actuating the high speed clutch and the emergency brake. Both brakes are an expanding type with shoes having 2.5-inch face, operating with drums on the rear wheels. The ignition and throttle levers are mounted below the wheel on the steering column. The gasoline capacity is 12 gallons. The speed is 15 miles an hour. The chassis is furnished with standard express and stake type bodies.

The Ford Delivery Body.

The Ford delivery wagon chassis is the same as is built for the Ford touring cars and it is equipped with an enclosed body with weight capacity of 700 pounds. The driver is protected by a long extension of the top that extends beyond the dash, and by half sides, which permit him to see behind without difficulty should this be necessary. The drive is at the left and the control is the same as with the well known pleasure vehicles. The maker is the Ford Motor Company, Detroit.

Stanley Steam Wagon.

The Stanley delivery wagon chassis is practically the same as is built for the seven-passenger touring cars, its power plant being a 30 horsepower boiler at a steam pressure of 125 pounds, this type being of the same capacity as were installed in the famed Stanley racing cars. The engine is the standard Stanley construction. The wheelbase is 136 inches and the 36 inches diameter wheels are fitted with 4.5-inch pneumatic tires. Regular equipment is a standard express body and a passenger body seating 11 persons besides the driver. These are produced by the Stanley Motor Carriage Company, Newton, Mass.

Mais Is Little Changed.

The Mais delivery wagons and trucks were shown, these being without change, but noticeable for the internal gear drive at the rear wheels. Extreme endurance is claimed for these driving gears by the maker, the Mais Motor Truck Company, Indianapolis, Ind., it being maintained that they may be driven a million miles. One of the features of this machine is the governor which automatically controls the speed and cannot be tampered with. The tread is 58 inches, this being two inches wider than standard to prevent driving in car tracks and unnecessarily wearing the tires.

The Mais construction embodies distinct variance from conventional practise, there being the unit power plant, with the motor having four-inch bore and 5.25-inch stroke, so designed that it may be quickly removed from the chassis and replaced by another in the event of need. The transmission is automatically locked so that the gears cannot be shifted until the clutch is disengaged, and no inexperienced driver can strip or damage the gears. The brakes are unusually large, affording better protection in congested traffic and on hills. These brakes are positive in action and are easily adjustable. The drive is at the left hand, another quality making for easy control. When the requirements of the purchaser are known the gear ratio is determined and the governor is adjusted so that there can be no abuse of the machine.

Another claim is the economy of maintenance and upkeep. The frame is exceedingly strongly constructed and the drive is such there can be no strain upon the driving system, it all being taken by the dead rear axle and the unusually large radius rods, which centre just behind the forward universal joint of the drive shaft. Four of these machines of 3000 pounds capacity, were recently delivered to the United States War Department for service at Fort Leavenworth, Kan., for ambulance work.

Martin Tractor.

Aside from the service wagons exhibited there was shown the Martin tractor, which was included in the exhibit of Knox productions, with it being displayed a trailer with two large wheels with steel tires and an open-end body loaded with long lumber. This was demonstration of the possibility of hauling building material that could not be loaded on a truck.

Fire Apparatus, Etc.

There was an interesting display of fire apparatus, including five chemical hose wagons and two pumping engines. Of the combination wagons one each was shown at the Buick, Pope-Hartford, Kelly, Knox and Locomobile stands, and the latest Knox fire pump and the imported Saurer fire pump. Of these the Buick was a light wagon equipped with a small chemical tank and small hose. The other apparatus was of the type known as combination, combining the functions of the chemical engine and the hose wagon. The creations were all the most recent and decidedly advanced as to construction, arrangement and equipment. The Knox fire pump has a 90 horsepower motor, six cylinders, and a large piston pump with 900 gallons capacity a minute. The Saurer fire pump is 60 horsepower and is rated at 900 gallons a minute. The Saurer apparatus will hereafter be built at Plainfield, N. J. These machines came in for a great deal of attention and the show was visited by a considerable number representing communities, a number of orders being taken for vehicles similar to those shown. The fire pumps are adapted for the service in cities where the buildings are lofty, but the chemical wagons are intended for use mainly in suburbs and residential towns, where economy of time is more essential than large fire fighting capacity.

Ambulances were displayed by the General Vehicle Company and the Autocar Company, omnibuses by the Atterbury, Autocar, Kelly and Stanley exhibits, with a Kelly sightseeing wagon and a Knox patrol wagon.

Refinement of Details.

With every exhibit there was noticeable refinements and attentions to details that demonstrated that each designer has considered the chassis construction with a view to insuring endurance and strength and at the same time utilizing every condition that would convenience work and result in time economy. The Grabowsky, the Sandusky and the Garford machines are so constructed that the motors

Digitized by Google

may be withdrawn from the chassis, the Sandusky without removing the radiator. With the others it is necessary to take off this member. The entire unit power plant is withdrawn with the Sandusky, but only the motor with the other two.

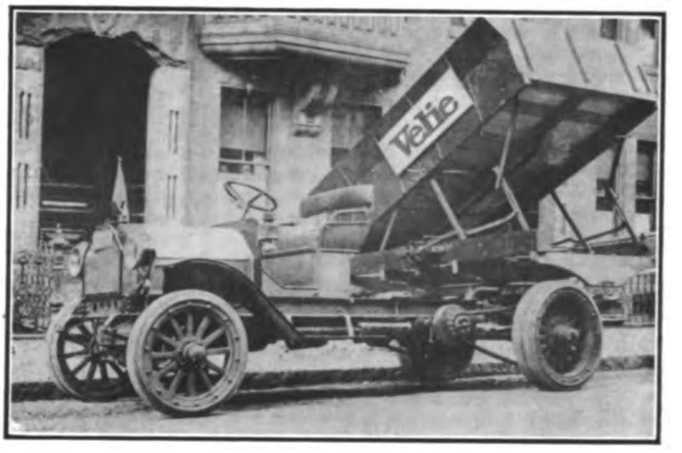
The radiator is mounted on spring supports by a large number of designers, this insuring against leaks that might be caused by rigid installations. The majority of the designers has constructed radius rods that are adjustable to compensate for the wear of the chains, otherwise known as stretching, and the manner in which each problem has been worked out is indeed interesting. With some of the trucks, as in the Locomobile, the jackshaft is mounted on spherical bearings, in gimbals, or in other construction so that the jackshaft is not affected by the distortion of the frame from road shock.

Chain cases are another detail that has received much careful study, these being designed to be oil and dust tight so that with occasional cleaning and replenishing of the grease there ought to be but little need of attention. The design of radius rods has been improved as a rule, these being heavier and with means for accurate adjustment. In several instances, notably with the Velie trucks, these are constructed with a spring buffer to absorb the shocks from road obstructions. The chassis frames are heavier and more strongly braced and in the Stearns truck, with a view to eliminating the stresses from vibration the motor has been mounted with the sub-frame carried in springs.

Because of the heavy duty required of the springs some designers have made hangers sharper in curve and deeper, to minimize possibility of striking when compressd to a limit, and to obtain freer action. Spring shackles have been very generally bushed with bronze and the spring bolts provided with means for lubrication. Brakes have been made larger and with equalizers to insure positive and certain action.

The placing of the tool box above the radiator in the dash before the driver is a convenience that can be appreciated by those who have been forced to search under a seat or elsewhere for tools that are absolutely necessary for the simplest adjustment. Another installation on the same machine is a little hand lever in a quadrant on the steering post by which the gasoline supply may be varied when there is need of giving the motor more fuel, such as during a hard climb or where the work is extremely hard, this being necessary with a long stroke motor.

The Mercury piston construction was noticeable for the simple manner in which the wristpin is retained. The channel in the boss for the wristpin is bored and at either side a small recess is made. The ends of the hollow wristpin are cut with a semi-circular recess to correspond with that in the side of the boss. The wristpin is placed with the recesses registering and then a brass pin is placed into them. This pin is bent when inserted, but by applying pressure it is straightened, the increased length filling the recesses and firmly fixing the wristpin. The brass pin is even with the walls of the piston and there is no possibility of the wristpin becoming loose, and the brass will not score or damage the walls of the cylinders. The process is inexpensive and the construction is regarded as being satisfactory, mechanically.



EDISON STORAGE BATTERY LETTERS.

Some 18 months ago, the Edison Storage Battery Company, Orange, N. J., began a distinctive educational campaign in the Army and Navy Journal, in which Miller Reese Hutchinson prepared a series of 52 letters, explaining in simple and non-technical language the methods of construction and operation of the Edison storage battery for commercial and pleasure vehicles. Those who have had opportunity to read but one or two of these letters have become imbued with the highly instructive material embodied therein, and the company has been besieged with inquiries as to how the full set might be procured. So insistent has been this demand that the Edison company has prepared, in reprint form, a neatly bound volume, over 100,000 copies of which have been distributed already. The letters are replete with information concerning this remarkable product and the treatment is such as to meet with decided approval by the general public. Mr. Hutchinson has been engaged to prepare a new set of letters, which will appear weekly in many journals throughout the country, and it is anticipated that they will be received in the same manner as his initial effort.

NEW VELIE DUMPING BODY.

A new type of dumping body has been brought out by the Velie Motor Vehicle Company, Moline, Ill., one of which has been fitted to a three-ton Velie truck and is being demonstrated by the Boston branch of the company. In the accompanying illustration is depicted the design and it will be noted that the carrying receptacle has been elevated and swung to the desired position by means of a roller bearing turntable.

This arrangement not only facilitates the unloading of

New Velie Dumping Body Which May Be Elevated to Any Angle and Swung in a Circle by Means of a Turntable.

coal, sand or brick, but eliminates wear and tear on the machine. Many times the driver will back up to and over the sidewalk to get his load into proper position for dumping. This creates considerable damage to the tires as well as to the mechanism of the car.

The new body is mounted on cross sills, these being attached to the upper part of the turntable mechanism, which is so constructed that the load may be swung easily to the desired location. The carrying receptacle is elevated to any angle by means of a hand operated winch. One of the features of the design is that it does not obstruct traffic in the street as it is parallel with the road and the sidewalk and does not extend into the former.

PENSACOLA ADOPTS MOTOR SPRINKLER.

In Pensacola, Fla., the warm climate makes it necessary that the streets be sprinkled frequently. The authorities decided recently to dispense with the horse drawn equipment and placed an order with the Autocar Company of Ardmore, Penn., for an automobile on which will be installed a cylindrical tank capable of carrying 300 gallons of water. The container is to be fitted to one of the commercial chassis and will be mounted upon sills to distribute the load evenly.

NEWS OF THE COMMERCIAL VEHICLE INDUSTRY.

Sells Taxicab Business to Develop Motor Omnibus Interests Along Broader Lines--New Companies Organized and Old Concerns Increasing Activities.

Changes in the taxicab situation in New York City have been predicted freely during the past year, and while many of the reported combinations and readjustments have failed to materialize, it is interesting to note that the New York Transportation Company has sold its taxicab business to the Connecticut Cab Company of that city. The purchasing company will take possession June 1, adding to its already well equipped line, more than 600 cabs, the stations and good will of the former concern. The statement of W. R. Meade, president of the New York Transportation Company, in this connection, follows:

"Since the adoption of the motor omnibuses on Fifth avenue, that branch of this company's business has developed with amazing rapidity. We have for a long time felt the necessity of concentrating our efforts on the Fifth avenue omnibus line, for the benefit both of the stockholders and of the public. Such concentration was manifestly impossible with the attention of the board divided between the omnibus line, the taxicab and livery business.

"On the other hand, we awaited an offer for our taxicab and livery plant from a concern that should not only be advantageous to our stockholders, but that should come from an organization able to maintain the high standard of service which our taxicab customers have come to expect from us.

"While I do not care at this moment to go into particulars as to our arrangement for the development of the Fifth avenue omnibus business, I am willing to say that the improvements made there will, we hope, within the next few years be even more important and noticeable than the change from horse to omnibus traction. The advantages, both to the stockholders and to the public, will be marked and important."

TO PRODUCE PARCEL DELIVERY VANS.

The growing importance of light delivery vehicles has brought out a number of new concerns for their manufacture during the past few months. Among the latest is the Manistee Auto Company, Manistee, Mich., which has been organized by seven local men with a capitalization of $51,000. Charles Elmendorf is president and general manager, and George M. Burr, secretary and treasurer. Suitable machinery has been purchased and work will begin in the near future on the reconstruction of a plant at River and Fifth streets, where low priced runabouts and parcel delivery vans will be manufactured under the present plans.

WOULD LOCATE IN SPRINGFIELD.

It would appear that Springfield, Mass., is to become an important distributing centre for motor trucks, if the reports from that city are verified by subsequent developments. It is announced that representatives of the General Motors Truck Company were in Springfield recently, seeking to interest local capital in the organization of a company with capital of $300,000 for the erection of a modern distributing plant, which should have charge of the disposal of the product of this concern in the New England states.

According to this information the representatives interviewed officials of the Morse-Readio Company, a local concern engaged in the manufacture of pleasure and commercial lines, which has been contemplating the construction of a new building on the east side of Dwight street. The proposition is said to have included a combination between the two companies in the organization of the distributing concern.

With the western men were two Boston architects who exhibited plans for a six-story structure, the first floor of which was to be utilized as a large automobile supply store. The second and sixth were to be reserved for the distributing business of the new company, the third for pleasure vehicles, with an entrance from Chestnut street, and the fourth and fifth for storage purposes.

WILL COMBINE FORCES.

Announcement is made by Henry F. Donaldson and Joseph Tracy, both of New York City, that they have associated themselves as automobile engineers to undertake consultation, research and development work, design and construction, laboratory and road tests. Both men are well known in the industry, Mr. Donaldson being president of the Society of Automobile Engineers, and Mr. Tracy a consulting engineer of wide experience. For the present, headquarters will be maintained in the office already established by Mr. Tracy at 118 West 39th street, and the laboratory in New Jersey will be retained.

EXPLOITING CINCINNATI TRUCK.

The drawings, patents, equipment and material belonging to the Power Car Company of Cincinnati, O., have been purchased by a concern to be known as the Cincinnati Motors Company. The new owner will be incorporated in the near future, and will take immediate steps to place in the market the car originally designed by the Power Car Company, under the name of the Cincinnati truck. Those behind the movement include Franklin Alter, Harry T. Alter and J. B. Doan, all of Cincinnati.

TO PRODUCE CARS IN ST. JOHN.

J. A. Pugsley of J. A. Pugsley & Co., St. John, N. B., was a visitor at the recent Boston show for the purpose of interesting capital in an effort to locate an automobile factory in St. John. It is understood that he was more or less successful and plans are under way for the erection of a plant, in order that construction work may be begun with at least 500 workmen in the early summer. Besides pleasure cars, the new concern will specialize in the construction of taxicabs for which there is said to be an unusual demand in New Brunswick.

ENLARGING CHASE PLANT.

Construction work will start in the near future on an important addition to the plant of the Chase Motor Truck Company, Syracuse, N. Y., maker of Chase commercial vehicles. The business of the concern has increased materially as the result of recent shows in various parts of the country, and many of the new orders call for special bodies on standard chassis. In order to handle this extra work an additional story will be added to the main building.

Digitized by Google

COLORADO WOMAN BECOMES TRUCK MAKER.

Probably the first woman in the country to direct the production of motor vehicles, no matter what the type, is Mrs. Nettie C. McIntyre of Denver, Col., who is not only the organizer but principal stockholder in the Wichita Falls Manufacturing Company, Wichita Falls, Tex., maker of the Wichita Falls truck. Mrs. McIntyre is a practical business woman, who has had large experience in other lines of endeavor, and her interest in the manufacture of commercial motor vehicles is due largely to the fact that she realizes the importance of this type of transport in solving many of the difficult problems of modern haulage in all sections of the country.

Until recently her home was in northern Colorado. While on a business visit to Wichita Falls she became directly interested in a unit control of spark, throttle, clutch and transmission, invented by C. A. McKiernan of that city. She believed that this feature would be particularly applicable to motor trucks and enlisted the financial support of J. A. Kemp and Frank Kell, both of Wichita Falls, in her project.

As a result of her endeavors the company was formed and a few vehicles of one and two tons produced in time to be displayed at the recent Kansas City show. Their success seems to be assured, from the fact that orders for 25 machines were secured during the exhibition.

The Wichita Falls truck was next displayed at the Denver show last month, and proved to be one of the chief attractions at the so-called Rocky Mountain district exhibit. The Wichita Falls Motor Sales Company has been organized in that city to look after the retail business in Denver and vicinity.

DECATUR TRUCK IN NEW HOME.

The Grand Rapids Motor Truck Company, which is the new name of the Decatur Motor Truck Company, maker of Decatur "Hoosier Limited" vehicles, is now located in its new home on North Front street, Grand Rapids, Mich., where the machinery and other equipment removed recently from the old plant in Decatur, Ill., is being installed as rapidly as possible. The change nowise affects the mechanical construction of the car, which has made such an enviable record during the past year that enlarged facilities for production were absolutely imperative.

The new company is capitalized for $600,000, and among the additions to the directorate are several prominent business men in Grand Rapids. M. E. Brackett remains at the head of the organization, and it is understood that the general policy of the company will be unchanged, except in the matter of greater production. In other words, the change was made solely for the purpose of broadening operation.

RECIPROCITY IN NEW JERSEY.

After once deciding by a majority of two votes that it would not adopt the so-called reciprocity measure, the Senate of New Jersey changed its mind, and the bill now awaits the signature of Governor Wilson. Of chief interest to the owners and operators of motor trucks is the provision of an additional fee of $10, over and above the registration fee which is based on horsepower rating, for commercial vehicles weighing unloaded more than 4000 pounds. This section is based on the contention that heavy freight vehicles wear the roads much more than other types. The reciprocity portion of the act follows:

"Any motor vehicle belonging to any person who is a non-resident of this state and who has registered such motor vehicle and has complied with the law of the state, territory or federal district of the United States in which he resides with respect to the registration of motor vehicles and the display of registration numbers, and who shall conspicuously display such registration number as required thereby, may be driven in this state during a period not to exceed 15 days in each calendar year, or on two or more occasions not exceeding in the aggregate the period of 15 days in any such year, without complying with or being subject to the provisions of sections 15 or 21 of the act to which this is a supplement, or either of them, or with any of the preceding sections of this supplement; provided that each day or part of a day during which any such motor vehicle is within this state shall be considered as one of the said 15 days; and provided, further, that the provisions of this section shall be operative as to any such motor vehicle owned by non-residents of this state only to the extent that under the laws of the state, territory or federal district of his residence substantially similar exemptions and privileges are granted to motor vehicles duly registered under the laws of this state."

MILLION DOLLAR ELECTRIC CONCERN.

Articles of incorporation have been filed with the secretary of state at Albany, N. Y., by the Buffalo Electric Vehicle Company of Buffalo. The capital is stated to be $1,000,000, of which $700,000 is to be common stock and $300,000 preferred. The company is to manufacture electric pleasure and commercial cars.

The directors named are: W. C. Feuchter, W. J. P. Seipp, Thomas B. Wheeler, Frank G. Lane and Marcus A. Alexander, all of Buffalo. It is announced that the complete details have not been worked out, but it is expected that the company is to be a merger of five existing Buffalo concerns, not necessarily now connected with the automobile industry.

WILL MAKE TRUCKS IN TEXAS.

The Twyford Auto Manufacturing Company has been organized in Houston, Tex., with capital of $400,000, for the manufacture of a four-wheel drive truck under the Twyford patents. Nearly 30 acres of land have been purchased at South Houston, this being located on the railroad line and close to the depot at that point. Work will begin at once toward refitting the building thereon for the production of mechanical vehicles, although no announcement is made as to the number of types or sizes.

The officers and directors include some of the most successful business men in that section, as follows: President, Monta J. Moore, president American Trust Company, Houston; vice president, J. N. Groesbeeck, director Hardy Oil Company, Houston; secretary and treasurer, Monta J. Moore, Jr., Houston; superintendent, R. E. Twyford, South Houston; directors, F. M. Robinson, automobile business, Houston; W. E. Richards, president American Loan & Mortgage Company, Houston; W. C. Berry, attorney San Antonio & Arkansas Pass Railroad Company, San Antonio.

FACTORY TO LOCATE IN JERSEY.

While the name of the purchasing concern has not been made public, it is understood that a new automobile factory is to locate in Garfield, N. J., a title to 16 acres of land in the section known locally as Plauderville, having passed from Matthew Van Kirke to August Hensel, who is acting for the real buyers.

JOHN N. WILLYS TAKES OVER GRAMM PLANT.

Undoubtedly one of the most important automobile deals of the past few months is disclosed in the announcement that John N. Willys of Toledo, O., president and sole owner of the Willys-Overland plants and allied interests, has bought the controlling interest in the Gramm Motor Truck Company, Lima, O., maker of Gramm vehicles. This news comes as a decided surprise to the industry, although it has been known in a general way that Mr. Willys has been casting about for a truck plant that was equipped as he thought it should be to meet the requirements of the commercial car users of America, and particularly of the more than 2000 Overland dealers.

John N. Willys, President Willys-Overland Company.

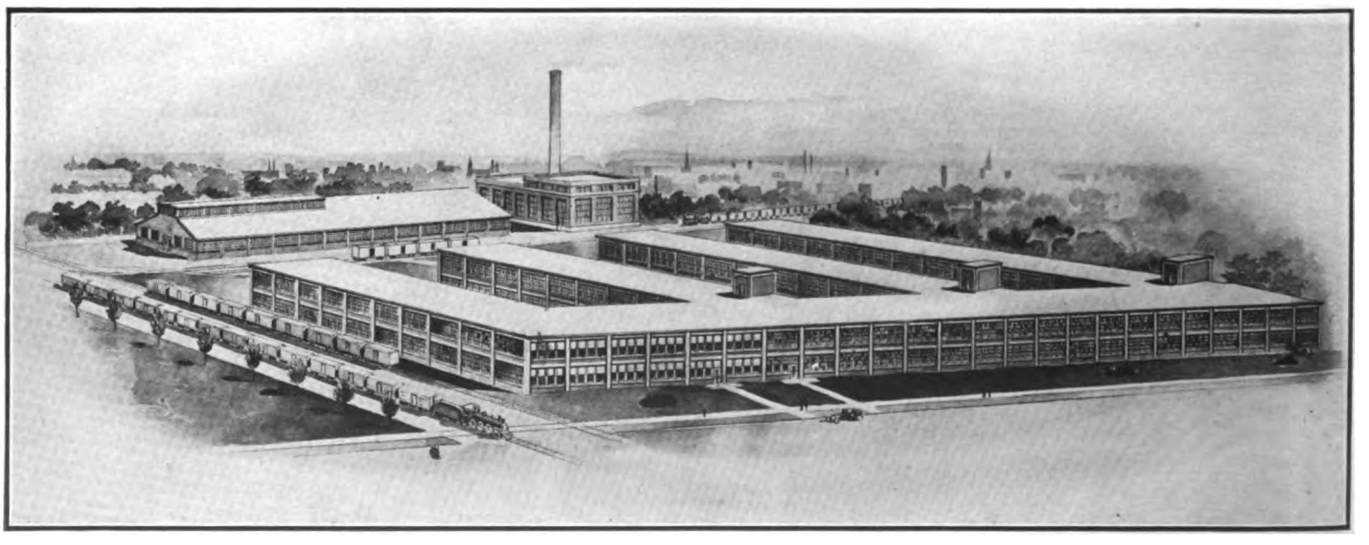
The combination appears to be ideal from many viewpoints. The remarkable rise of Mr. Willys in the automobile business since he took over the Overland plant has been a subject of much interest both in and out of the industry. B. A. Gramm is without doubt one of the best informed and most experienced truck manufacturers in the country. His company was among the first to undertake the solution of the body problem, and this feature alone is a business in itself.

The Gramm truck plant is one of the largest in the world, devoted exclusively to the manufacture of commercial cars. The buildings occupy 22 acres of ground, and 6.25 acres are under one roof. Twelve hundred men are employed. All of the equipment is of the very latest and best that can be purchased. The automatic machinery is the most modern. The buildings are of steel and reinforced concrete, and are valued at $1,250,000. No announcement has been made concerning the plans of the Gramm company under the new management.

KELLY-SPRINGFIELD TIRE EARNINGS.

The Consolidated Rubber Tire Company, Akron, O., maker of Kelly-Springfield tires, reports that the net earnings of the company for the year 1911 were $114,020, an increase of $28,505 over the previous year. The gross sales for 1911 were $3,383,532, as against $2,160,915 for 1910. The income account for the two years is shown by comparison as follows: Interest, dividends, etc., $95,562 in 1911, and $150,402 in 1910; total receipts, $2,479,094 and $2,311,317, respectively; expenses, taxes, etc., $3,365,074 and $2,225,802, respectively; net earnings, $114,020 and $85,515, respectively.

GOODYEAR BRANCH IN MEXICO.



The Goodyear Tire & Rubber Company, Akron, O., maker of Goodyear tires, has leased for a long term of years a three-story building at the corner of Avenida Juarez and Balderas, Mexico City and the structure is being remodelled to serve as a special factory branch in Mexico. The officers of the Mexican company are: Director general, J. C. MacFadyen, formerly in charge of the company's branch in Indianapolis, Ind.; secretary and treasurer, S. F. Fuller, formerly with the Mexican Clay Products Company.

GRANT TRUCKS IN BOSTON.

The Grant Motor Truck Company has been organized in Boston, with Harry F. Grant, twice a winner of the Vanderbilt Cup race, as treasurer, and Frank S. Corlew as sales manager. It is announced that the factory will be located in Cambridge, Mass., where a one-ton vehicle will be produced, capable of carrying at least 50 per cent. overload. Temporary offices have been opened in the Shoe & Leather building, Boston.

AIRLESS TIRES IN ALLIANCE.

The Board of Trade in Alliance, O., announces it has procured for that city the plant of the Davies Manufacturing Company of Detroit. The concern produces airless automobile tires, and is incorporated for $150,000.

Plant of the Gramm Motor Truck Company, Lima, O., the Controlling Interest in Which Was Acquired by John N. Willys, Recently.

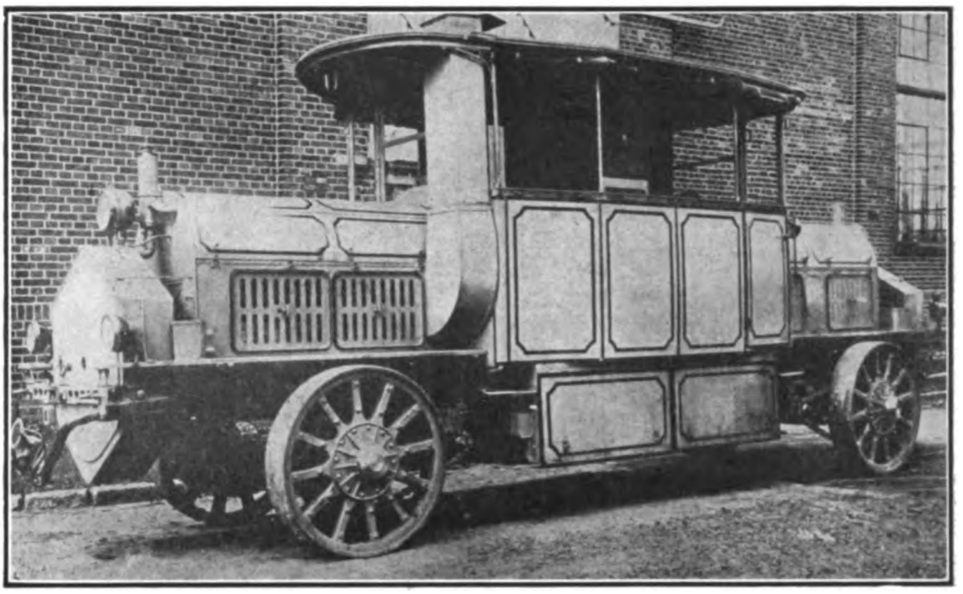
MULLER POWER CAR AND ROAD TRAIN.

Interesting Application of Mixed Gasoline-Electric System in Hauling Heavy Loads Long Distances Over All Conditions of Road Surfaces.

By Joseph P. Fox.

THOSE interested in the matter of transporting heavy loads through districts where it has been found impractical to construct railroads are aware of the importance of the motor road train, but there have been certain difficulties in the production of suitable vehicles which at first appeared almost insurmountable. Differing types of power, steam, gasoline and electricity, have been tried, and it has been demonstrated very effectually by experience that the main feature is not so much that of the power generator, but the means for transmitting this power to the road wheels.

The real advantage of the road train lies in the proper division of the weight to be carried over a large number of wheels, and of having as many of these wheels as is possible act as driving members, thus doing their part in the work of propelling the whole. It is in unity of action that the greatest efficiency of the road train is realized.



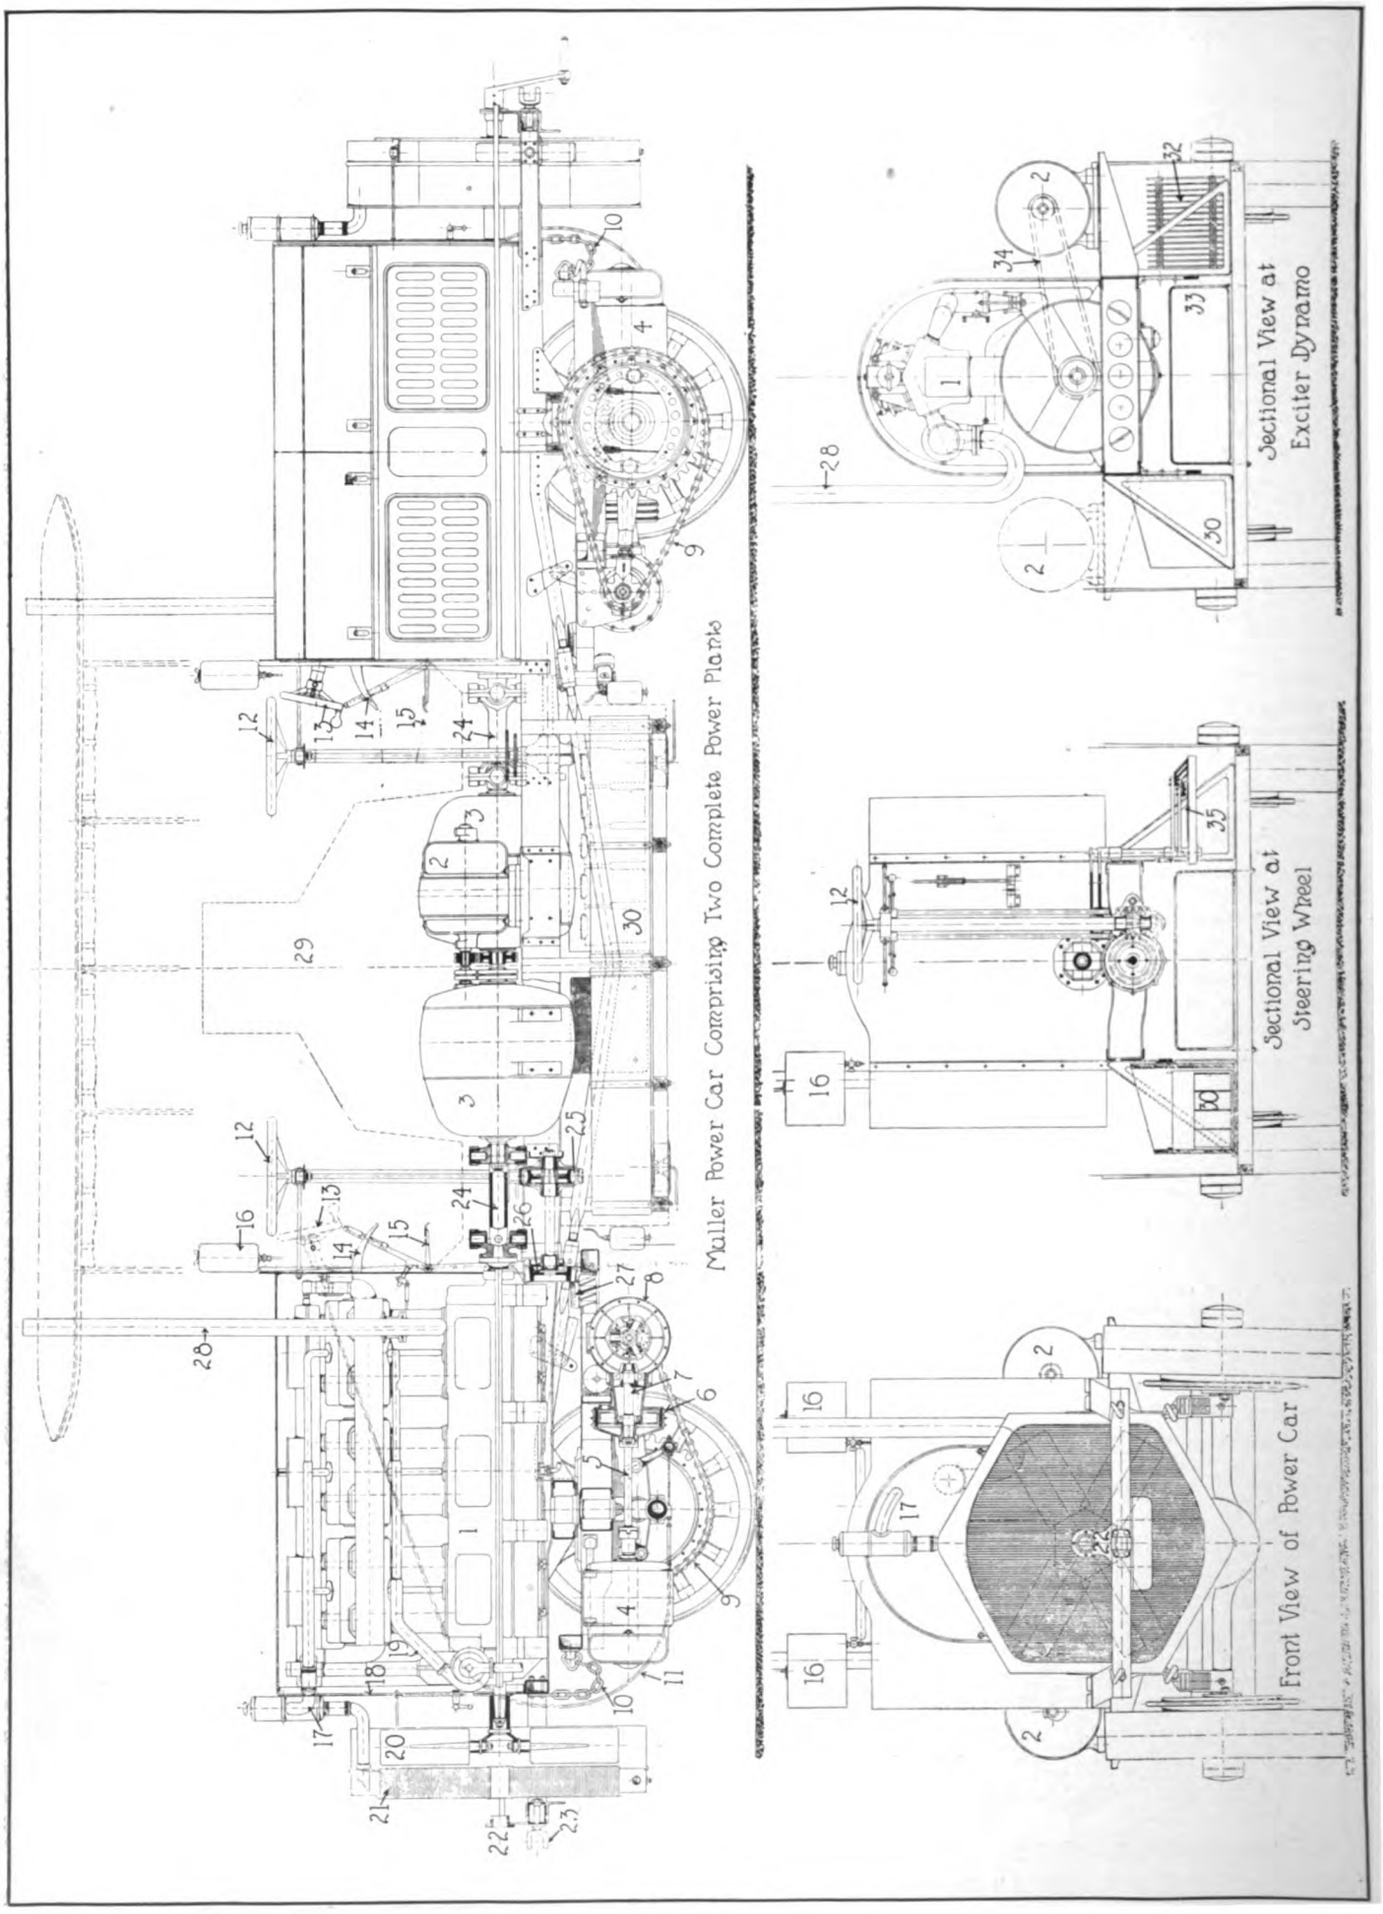
Even in countries well served by railroads, there are sections, towns and cities lying between and on hills, which in many instances offer splendid opportunity for the institution of such service as is contemplated by the road train. It is of particular advantage, however, in the transportation of mining products and supplies; timber, stone, cement and other building materials, and in the great food growing centres where quick movement of large quantities of produce is of the most vital importance.

Of course, if the road train is to supplant present methods, it must possess positive operation, sufficient to guarantee against extended delays which could cause serious inconvenience or loss. In addition, it must be able to transport goods or material at a cheaper rate than the means for which it is offered as a substitute. It is easy to understand that such a train is confronted by serious handicaps, and among these may be mentioned hills, bad roads, curves and corners, the last named of which must be taken within a comparatively short radius.

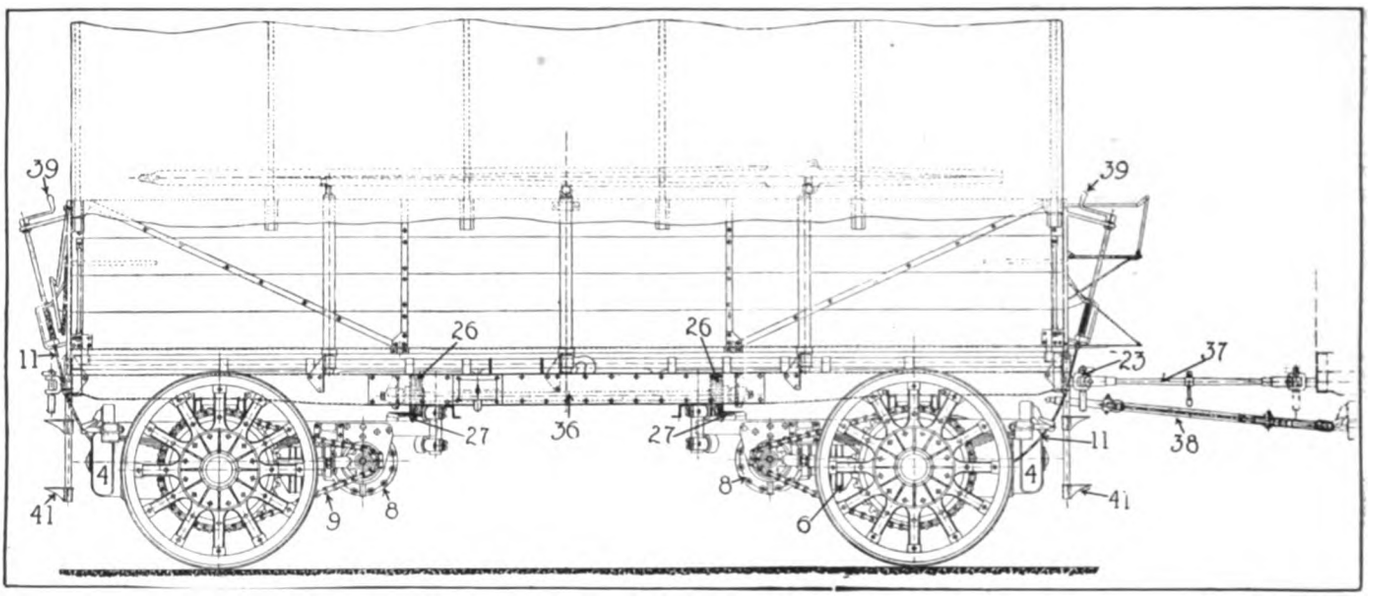
In fact, it may be stated that it is in the matter of rounding curves and corners in which the constructor has found the greatest difficulty of all. Each car, or each member of the train, must have the ability to describe automatically the same arc of a circle as the leader without any extraordinary skill or particular attention on the part of the driver, other than that usually required in turning corners with a single vehicle. In other words, the entire train must act as a unit. It is interesting to note, in this connection, that a number of road trains have been produced, which have demonstrated their ability to do this. It will be seen that it is necessary that when four wheels are used for each car, they shall all be steering wheels and if possible driving members as well.

By dividing the load over a number of cars and therefore over a large number of wheels, it is possible to operate over sandy roads or soft ground without sinking too deeply. If one set of wheels were loaded more heavily than the others they might sink into the path so as to make driving very difficult, if not impossible. Furthermore, a proper distribution of the load insures that each set of wheels shall have sufficient adhesion to the road surface at all times, even though some may be in such position on bad or slippery ways as to be of practically no service for the time being.

To obtain the best results, therefore, it becomes necessary above all things to have the best possible means of transmitting power to the driving wheels. It must appear that it hardly would be practical to have a separate power generator in each car, as this would require too much attention and take up altogether too much valuable space. As a result, the trend of design has been confined principally to a central power plant with a simultaneous transmission of power to the various driving wheels.



Complete Muller Power Car with Its Double Power Plant, Elevated Exhaust Pipe, Iron Tired Wheels, Etc.



As power generators, either the steam boiler and engine or the gasoline motor may be used, and as a medium of power transmission to the wheels, either electricity, compressed air or oil hydraulics would appear to be better qualified for this work than any mechanical means. Instead of power generators, it is possible that compressed air tanks or storage batteries might be employed, but this hardly would be practical, except for regular trips over short distances and under specially favorable conditions for refilling the tanks or recharging the batteries.

The generation of power by gasoline motor and the transmission of this power by means of an electric dynamo and driving motors, seems to have exceptional qualifications not possessed by other systems. This so-called mixed system has been tried with success in the construction of single vehicles, and it must be added that it is as near

Digitized by Google

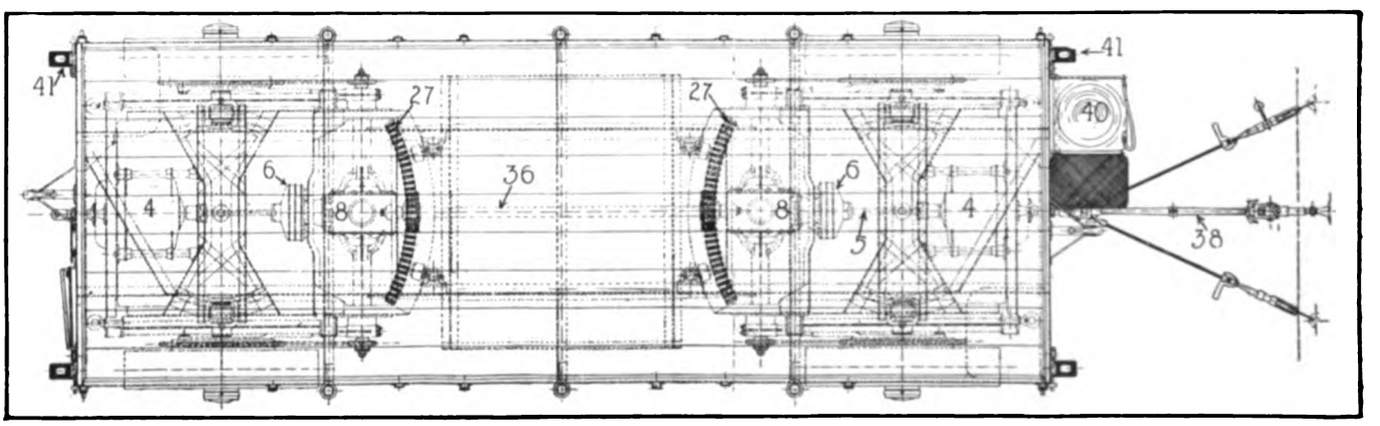
Side View of Muller Utility Car, Showing Relation of Parts and Method of Connecting in Making Up the Train.

ideal theoretically as can be imagined, especially with road trains. There is ample space for the assembly of the dynamos and reserve batteries, which do good service as well in lighting the car and in starting the motors. The transmission of energy to the distant cars being by the simple means of a cable, which is not in any way sensible to shocks, twists or differences of temperature, is an advantage of great importance peculiar to this system.

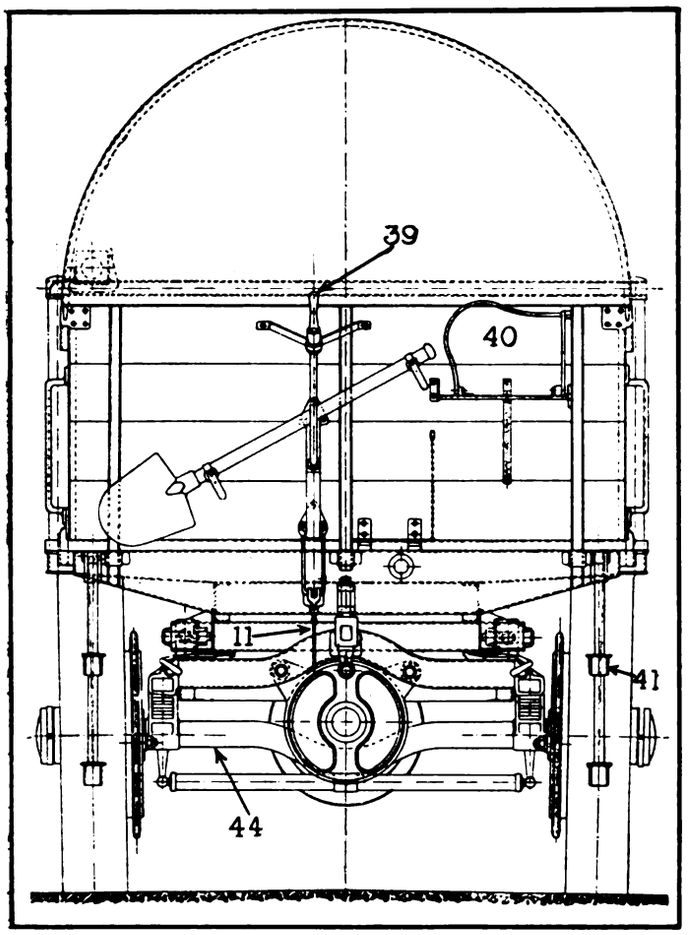
There is perhaps no service for which the trackless train is better adapted than military work, and here this so-called mixed system has been proven practical by severe tests under all conditions and over all kinds of roads. The wonderful elasticity and reserve power, as well as the quick and simultaneous transmission of power to all driving wheels, has made it possible to overcome road conditions that otherwise would seem to be impassable.



The war departments of various European countries from time to time have experimented with the road train, and the encouragement offered to the manufacturers has been of great assistance to the industry. This is particularly true of Germany, which has established an experimental corps composed of what are termed "Genius Soldiers," for the purpose of thoroughly testing out everything worthy of note which is brought to the attention of the government. Suggestions for improvement and for new construction are made by this department, subsidies and prizes are granted to those who have qualified; in fact, everything possible is done by the government to encourage progress along these lines and to keep the war department abreast of the situation. This applies to every line of activity.

The road train described herein is that of the firm of W. A. Th. Muller (Strassenzug Gesellschaft) Street Train Company, of Staglitz, near Berlin, and was built especially to comply with the requirements of the German War Department. It is composed of one power car and six trailers, the entire train being mounted on iron tired wheels. Each trailer, as well as the power car, has two electric motors, each driving a pair of wheels, therefore making each wheel in the entire train a driving member.

This train carries a load of from 30 to 32 tons, at a speed of 12 to 16 kilometers (about 7.5 to 10 miles) an hour. The load is divided evenly on the six trailers, making an even pressure on each set of wheels of about 2.5 tons. The power car carries no load except the power plant and the help necessary to operate the train.



The iron tires have a width of 200 mm (about 7.8 inches), so that the loaded trucks are able to travel over soft and sandy surfaces without sinking into them to any extent sufficient to impede the progress of the train. Through extended experiment it has been found by the German government that a train of this type fully loaded can operate up a 10 per cent. grade over soft ground and pathless fields.

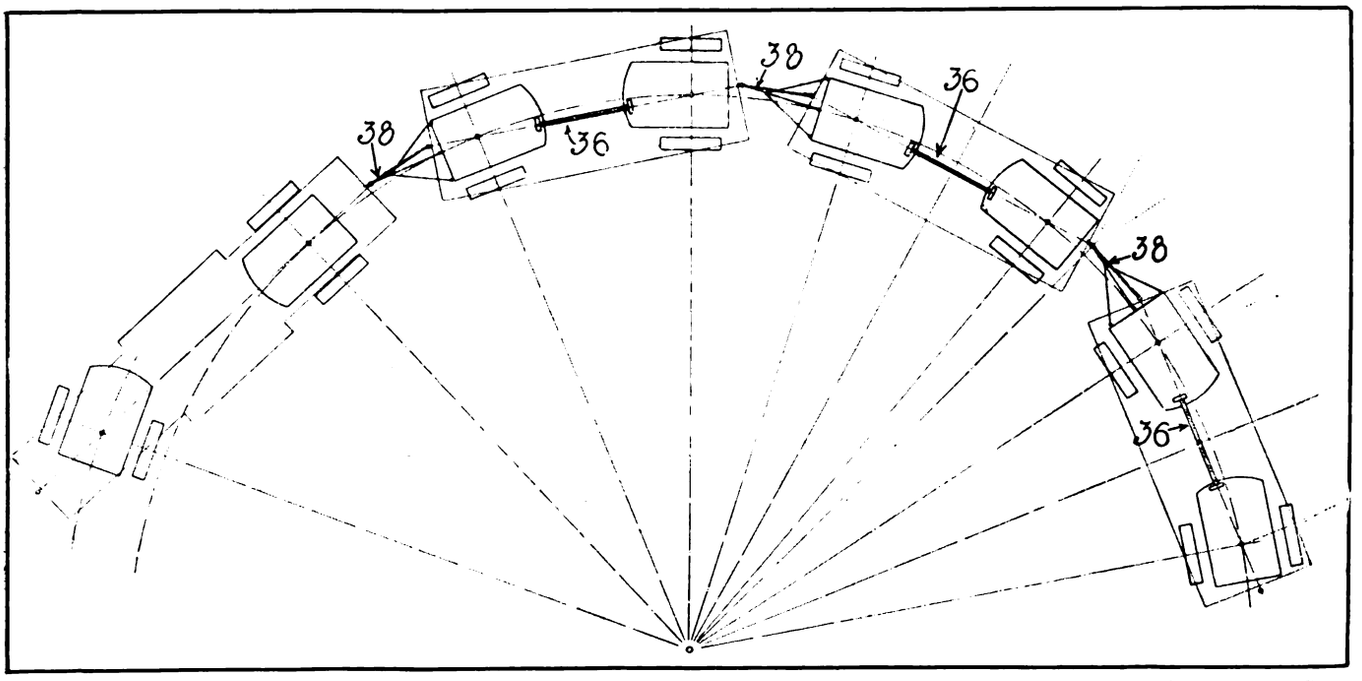
An accompanying page plate presents a drawing of the power car, comprising two exactly similar, complete and independent power plants, each made up of a six-cylinder gasoline motor attached to an electric dynamo, whose anchor serves instead of the customary flywheel to steady the operations of the motor. From the two ends of the dynamo shafts, which abut each other in the centre of the car, there

Top View of Muller Utility Car Chassis, Outlining Electric Driving Motors, Swivelling Trucks, Braking System, Etc.

Digitized by Google

End View of Utility Car, Presenting Position of Brakeman's Seat, Etc.

are two Renold silent chains for the purpose of driving an exciter dynamo. The transmission of energy from the generators to the electric power motors which propel the driving wheels is by means of a direct current which is converted into electromotive force of 400 volts by the exciter dynamos.



The coupling between each motor and its dynamo is by means of a shaft and two universal joints, which in order to keep the crankshaft and anchor in rigid connection without the possibility of any play, is constructed especially strong and of the best possible material. Each six-cylinder motor has a bore of 155 mm and a stroke of 170 mm (5.9 by 6.7 inches), rated at 90 horsepower at 850 revolutions a minute. The fuel is either "benzol" or heavy gasoline.

As will be noted in an accompanying sectional view, the valves are assembled in the cylinder heads and the intake and exhaust are on opposite sides. Ignition is of the Bosch make-and-break type. Cooling is by means of water circulation through a flanged cooler, this being set so low that the fan for supplying the cold air can be driven directly from an extension of the motor crankshaft. In order to prevent dust from entering the engine room, the front part of this room, under the hood, is partitioned back of the fan in such manner as to prevent the air current passing through, but notwithstanding this obstruction, the fan is fully adequate for the requirements.

That the motor may be started by hand, an opening comprising a sleeve and bushing is situated in the centre of each cooler through which the starting crank may be inserted. This sleeve and bushing are held in place by a frame extension which holds the cooler in position, and this extension is fastened to the chassis in such manner that it can be removed easily to permit necessary repairs. As in this assembly the cooler is stationed below the motor, it has been found necessary to arrange a special tank sufficiently high on the dash, within the hood, to allow the escape of any air or steam which might accumulate.

Together with the two complete power plants, the power car carries 500 liters (about 120 gallons) of fuel, and a complete supply of electric apparatus necessary for the control of the vehicle. In this equipment is included an Edison storage battery of 40 cells, employed for starting the gasoline motors, through the medium of the main dynamos, which, when thus used, are transformed for the time being into electric motors. This battery also is employed for lighting and for operating electric brakes, one at each road wheel.

All control levers on the power car, which have to do with the steering or braking of the train, are attached to or near the steering gear, and within easy reach of the

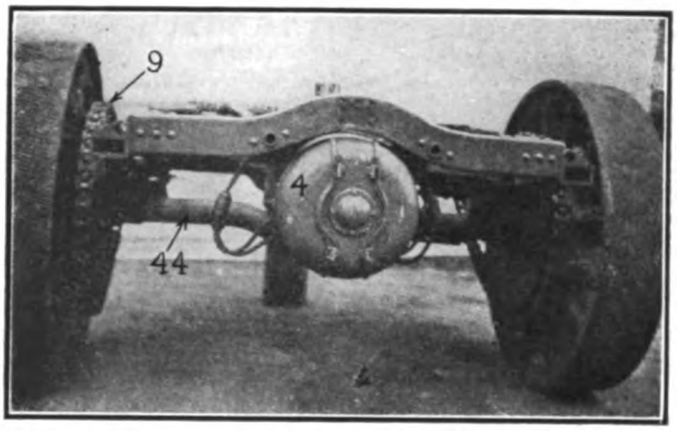
Digitized by Google

driver's seat. All are in duplicate, as well as being assembled from interchangeable parts.

By reference to the page plate and other drawings herewith, the following figures will better explain the different parts: 1, six-cylinder gasoline motor; 2, exciter dynamo; 3, main dynamo; 4, electric motor on driving truck; 5, motor shaft; 6, brake operated by magnet; 7, pinion shaft; 8, casing for crankshaft, driving and differential gears; 9, chain for driving road wheels; 10, chain to determine extreme lateral movement of driving truck; 11, Bowden cable for operating the wheel brakes; 12, steering wheel; 13, brake wheel; 14, lever for regulating motor; 15, lever for operating magnetic brake; 16, oil tank; 17, water conduit; 18, partition; 19, water pump; 20, ventilator; 21, cooler; 22, sleeve for starting crank; 23, clutch for connecting rod between cars; 24, shaft between motor and dynamo containing two universal joints; 25, worm drive for steering gear; 26, pinion gears operating turntable; 27,

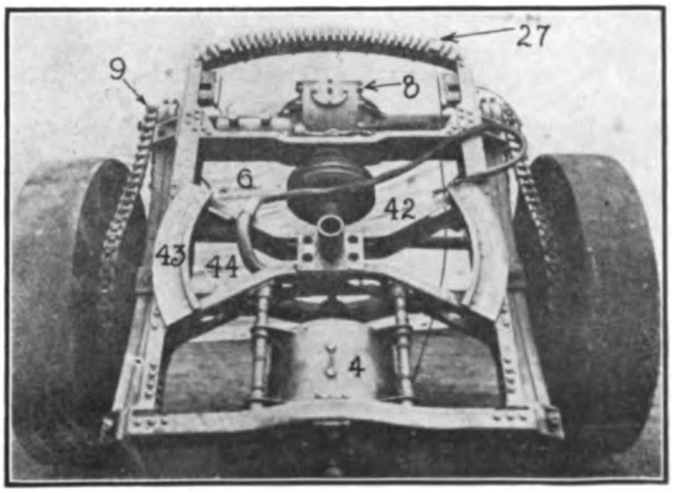


Utility Car as Seen from the Front, and Method of Controlling It When Detached from Train.

turntable quadrant gear; 28, exhaust for gasoline motor; 29, double seat with tool boxes; 30, electric battery; 32, resistance regulator; 33, fuel tank; 34, chain driving exciter dynamo; 35, electric switch for control of speed; 36, connecting shaft for steering train; 37, connecting rod between cars; 38, steering pole; 39, crank for operating hand brakes; 40, brakeman's seat; 41, step; 42, socket for pivot in turntable; 43, turntable supporting track; 44, tubular axle.

The larger drawing in the page plate illustrates the assembly of the power car with its double power plant. The front view shows the position of the cooler, water conduit, exciter dynamo, etc. The first sectional view presents the location of the worm driven steering gear, storage battery, switch and control levers. The last view is that indicating the placing of the resistance regulator, chain drive for exciter dynamo, cylinder head valves and exhaust.

The double power plant is held not only to possess the



End View of Swivelling Truck, Indicating Location of Electric Driving Motor.

advantage that the train will not be placed out of service because of a defect in one of the machines, but in that it increases the efficiency of the assembly, insofar as that is possible, by operating the train on a comparatively reduced fuel consumption. When travelling over hard level roads it is claimed that it is possible to haul the train at a normal rate of speed by one motor, delivering only 60 of its 90 horsepower.

The double seat not only accommodates all the help necessary for the operation of the power plants, but the compartments underneath are so constructed as to be available for carrying tools and the reserve parts that may be required on a long journey. The double steering gears are each composed of a worm drive from the shaft of the steering wheel, which is connected with and drives a shaft and pinion gear. These pinion gears mesh with sectors fixed on the upper surfaces of the two trucks, which carry the axles and driving wheels.

In order to make the turning or steering of the trucks easy for the operator, the body of the vehicle is supported in its pivoted position by steel rollers assembled on ball bearings and resting on tracks supported by the trucks. The curved sector attached to the end of the truck frame, which is driven by the pinion gear above mentioned, is guided between rollers fixed to the frame of the chassis.

As shown, these trucks, which are practically the same in the utility cars as in the power car, are constructed of a U shaped steel frame supported on the two driving wheels by means of the springs and axle. The truck wheels are driven by means of chains, connected by cross shafts, differential and centre shaft to the electric motor. The cross

Top View of Swivelling Truck, by Means of Which Every Movement of the Train Is Controlled.

and centre shafts are connected in the usual manner by pinion gears. The shafts and differential, as well as the motor, are enclosed in dust proof cases and suspended from the frame of the truck.

On the shaft of each motor is an electric brake, operated by a magnet and controlled from the driver's seat. As each utility car has one of these brakes, it can be seen that with a single movement of a hand lever, the operator is in a position instantly to apply the brakes throughout the entire train.

Within the chain drum of each wheel also is assembled an expanding brake, attached to a balancing member, which may be operated from the brakeman's seat situated at the end of each car. The controlling medium is that of a crank attached to the upper end of a slanted spindle, this spindle having at its lower end a screw and sleeve to which are attached Bowden cables. These cables are attached to the balancers of both trucks, making it possible for the brakeman to apply the brakes on all four wheels at the same time.

As a rule, the electric brakes are quite sufficient to control the train, and the hand brakes may be termed emergency members. It is intended that these shall be used only when the electric brakes are out of order, or in case it is found necessary to hold a single car that has been switched off in making up or detaching the train.

It has been noted that the power trucks on the utility cars and on the power car are practically the same, the only difference being that in the former the body of the vehicle is supported on the centre pivot and on shoes sliding on the curved tracks which form a turntable, while in the latter steel rollers are substituted for the sliding track. An accompanying drawing shows the entire train as it would appear while rounding a curve, and it will be seen that the power trucks of each car are swivelled on their respective turntables. Each truck is turned to a corresponding angle with the radius and the curve to be followed. This is accomplished by means of the steering shafts, which are geared so as to turn the sectors of each truck at the same proportionate angle, but in an opposite direction to the one preceding it. These steering shafts are assembled slidably in their sockets or bushings in order that they may be relieved of all shocks or thrusts. Strong shafts with double universal joints attached to spring bearings connect the cars as can be seen in the illustrations. For making up trains or moving the single cars around independently of each other, a very novel plan has been adopted. As shown in an accompanying photograph, this consists merely of connecting a power cable to the car, by means of which it is supplied with power from a stationary storage battery. The car then may be started and stopped, within the radius permitted by the cable, from the brakeman's seat, a lever being provided for that purpose as shown. Steering is accomplished by means of a wagon pole, easily attached, and this pole also can be used to good advantage in steering around very sharp corners

LARGE ORDER FOR PEERLESS TRUCKS.

Throughout the country the leading express companies are replacing their horse drawn equipment with the more progressive form of transportation, and it is interesting to note that the exhaustive tests conducted by the engineers of these concerns have resulted in a favorable report and the adoption of the mechanical transport.

Different size cars were placed in service and operated under conditions more exacting than the horse drawn equipment. During this work they were watched carefully by the engineers and traffic experts who made accurate estimates of the performances of the vehicles as compared with other methods of hauling.

The American Express Company, one of the leading organizations of its kind, experimented with the automobile and some time ago placed five Peerless trucks, made by the Peerless Motor Car Company, Cleveland, O., in service. These were given severe usage and the result was that the company placed an order for 11 more machines. In the accompanying illustration is shown eight of the new vehicles which have been tested out and are ready for the fitting of special bodies.

Part of a Fleet of Peerless Trucks Purchased by the American Express Company Which Adopted These Vehicles After Exhaustive Tests.

PUEBLO BUYS NEW PRISON VAN.

Pueblo, Col., which experimented with the automobile police patrol, utilizing a second hand pleasure vehicle, has replaced the machine with a Cadillac to which has been fitted a special body so constructed that it will accommodate a large number of prisoners as well as officers.

MILTON, MASS., HAS NEW PATROL.

Chief Maurice Pierce of the Milton, Mass., police department has purchased a new automobile police patrol to replace the old vehicle which has been in service for over two years. The new machine provides seating capacity for five persons.

New Commercial Car Accessories

Young's Self-Starter.

A device whereby gas lamps may be lighted and extinguished from the seat by the throwing of a switch, is manufactured by A. G. Young, Pittsburg, Penn. The selling agent is William H. Pollock, 607 Webster avenue, of the same city. The equipment consists of a dash valve which controls the flow of acetylene, switch and wire, and burners. The last named are fitted with a practical sparking arrangement, so constructed as to withstand hard usage as well as heat. When the switch is operated the regular current is utilized to jump a spark across the gap at the burners, igniting the gas. It is claimed that the device will save 50 per cent. on gas bills, may be attached in a few minutes by anyone, and does not require any attention whatsoever.

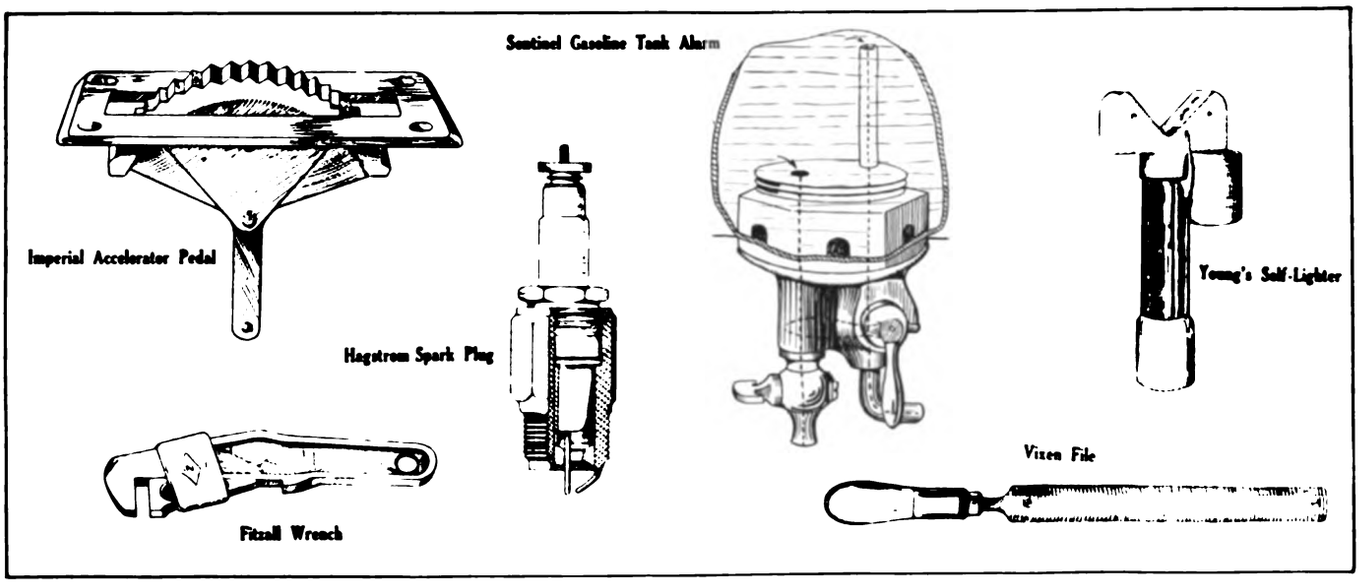
Fitzall Wrench.

Providing instantaneous adjustment and a positive grip are the features emphasized of the Fitzall wrenches, manufactured by the Standard Wrench & Tool Company, Providence, R. I. The tool is free from adjusting nuts, being constructed in three parts, these operating on the inclined plane or wedge principle. In practise the movable jaw member may slide forward or backward and when pressure is applied, the tooth block locks the parts securely. They are made in different sizes and in the regular form, as well as for working on pipes. It is claimed that the only part subject to wear is the tooth block and as this is removable it may be replaced easily, and the member is not expensive.

Vixen File.

The superior abrasive qualities of the Vixen file, the product of the Vixen File Company, Philadelphia, are said to be due to the peculiar construction of the teeth. These are semi-circular and are cut especially deep. The tool is adapted to soft and tool steel, cast and wrought iron, bronze, brass, etc., and it is claimed that owing to its self-clearing properties will cut soft metals without clogging, will not slip or chase, and operate equally well on greased surfaces. It is claimed that the Vixen product may be resharpened from four to six times, this depending upon the number of teeth to an inch. The files are made in different sizes and styles.

Hagstrom Spark Plug.



The Hagstrom Bros. Manufacturing Company, Lindsborg, Kan., has brought out a new type of spark plug, the feature of which is the fitting of a porcelain guard in the shell proper, and surrounding the exposed end of the electrode. It is claimed of this arrangement that oil is prevented from working up into the plug, that the main porcelain is protected against undue heat, and that short circuits by carbon are eliminated.

Wixon Accelerator Pedal.

An accelerator which is operated with the foot in a flat and natural, as well as relaxed position, is being marketed by the Imperial Brass Manufacturing Company, Chicago. The device is know as the Wixon and consists of a flat plate for attaching to the floor board carrying a pivotally mounted half-wheel which is provided with teeth designed to prevent the foot from slipping when operating over rough roads. Attached to the wheel is a lever to which is connected the rod leading to the carburetor. It is substantially constructed and may be attached to any car in a few minutes.

Sentinel Fuel Tank Alarm.

The Sentinel gasoline tank alarm, made by Zwillinger & Feldman, New York City, consists of a standpipe which extends upward from the bottom of the fuel container through which the fluid flows until it falls to the level of the pipe, thus signalling the operator that the regular supply is exhausted. To utilize the reserve, a valve is turned and the device may be locked with a key to prevent tampering with the fuel supply. It is attached easily to any tank, the operation involving the cutting of a circular hole about 1.5 inches in diameter in the bottom of the container, the removal of the nut from the latter to allow the washer to rest between the bottom of the tank and the flange of the alarm, and the screwing down of a nut on the inside of the tank. The device is also equipped with a filter.

Some Recent Accessories, Including an Acetylene Lighting Device, Accelerator Pedal, Fuel Tank Alarm and Quickly Adjusted Wrench.

TRANSPORTATION EFFICIENCY.

That the mechanical transport is capable of being operated in a manner to bring about decided economy over horse drawn equipment is now generally conceded. So many concrete instances have been presented that there can be no mistaking this point. However, there is one important phase of the situation that is being recognized more largely by both the business man and the vehicle manufacturer. In order to secure the utmost economy with the motor truck, it must be worked as nearly to its maximum efficiency as is practical.

With some lines of business this side of the problem is more easily solved than with others. Each delivery system has its own particular features, and while it may be necessary to rearrange existing methods to accommodate the newer type of haulage in the retail grocery or department store service, for instance, this is a condition which can be handled largely by the delivery superintendent with comparatively slight assistance from other sources.

Special attention is now being paid to those lines which in the natural order of things may be expected to utilize vehicles of large carrying capacity, reference being had more particularly to the coal, lumber and kindred industries. With these the body equipment is decidedly essential, but the complete solution does not end with the chassis and body.

Efficiency in motor transportation means that the vehicle shall be kept moving with a useful load. Obviously, with some industries it is an impossibility to carry a useful load in both directions, and with such the maximum efficiency of the truck is measured by the length of time during which it can be thus employed. Delays at either end of the line must be eliminated first of all, and this presents a situation in which others than those directly connected with the manufacture of automobiles or bodies are called upon to exercise their ingenuity.

WEATHER EXTREMES AND HORSES.

According to the records of the board of health in New York City, more than 20,000 horses died in the streets of that city during 1911. Seventeen hundred were removed by contractors during the fortnight ending July 8. In one week in December 500 were lost in a similar manner. It would appear that extreme cold with its attendant snow and ice, was nearly as fatal to horses as extreme heat.

These figures should prove of interest to the man who is contemplating the installation of commercial motor vehicles, inasmuch as the extremes of temperature in either direction are by no means fatal to the mechanical transport. It ought also to be remembered that the loss occasioned through death by no means represents the sum total of the business loss occasioned by dependence upon animal transportation as the result of the weather, since the motor truck is able to work at its maximum capacity when it is unsafe to attempt to utilize horses.

MOTOR TRUCKS AND ROADS.

As was perhaps to be expected, one result of the bill introduced into the Massachusetts Legislature seeking to limit the weight of industrial transports using the public highways has been to call direct attention to the economic value of the vehicles. And it is of special significance that the motor truck has demonstrated its ability along this line so satisfactorily that in every case there has been no disposition to dispute its superiority.

In the first place, it must be admitted that roads, good or bad, exist for the benefit of the public. Little thought has been given to this matter in the past. Governmental reports show that much of the so-called high cost of living is directly traceable to the difficulty experienced in getting farm products, for instance, to the market, and by no means all of the transportation cost is charged to the railroads.

If this problem is to be solved by a more general use of motor trucks, it would appear to be good economics to consider the construction of roads which will stand up under modern usage. No one seriously questions the fact that the transportation of the future is to be by mechanical means. It is poor public policy to discriminate against a type of transport of such large importance as the motor vehicle.

THE A B C OF MOTOR TRUCK OPERATION.

A Simple Exposition of the Principles Underlying Operation, Maintenance and Repair of All Motor Driven Commercial Cars, Describing Details of Their Components. Part XVII—The Progressive Transmission and Other Types.

By C. P. Shattuck.

OTHER forms of sliding gearsets are utilized in motor truck construction besides that of the selective type previously described but they all serve the same purpose, that of providing a variable rotation of the driving wheels without necessarily changing the speed of the motor to bring about the desired results. The components of the gearbox or transmission in the mechanical transport are subject to stresses not encountered by the mechanism of the pleasure vehicle, and in designing and constructing these members the engineer has made them sturdy, of high grade material and as simple as possible. To prevent damage by careless operation devices are incorporated so that changing from a forward speed to a reverse with machine moving cannot be accomplished except by design.

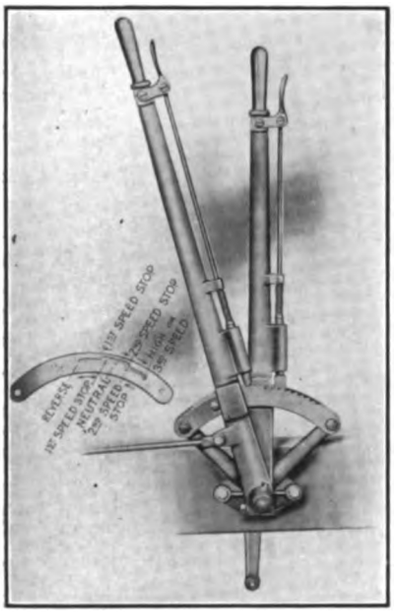

Fig. 69—Depicting Quadrant and Lever Utilized with Progressive Type of Transmission.

In the selective type the changes of speed are effected by a lever at the side of the driver and this may be at the right, left or centre, according to the design of control. The quadrant, or metal frame is so slotted that the lever may be pushed backward or forward in any one of the three parallel channels. For example, if the lever be moved forward in one channel it engages or brings into mesh a set of gears which produces the low speed. Bringing the lever directly back releases the gears already in mesh and slides a different set into engagement; for instance, the second speed. To shift into the third, the lever is moved sidewise and thrust forward into the direct or third speed. The fourth is obtained by a backward movement, and the reverse by moving the lever into the third channel, but before this is done a catch or stop member must be released. This device is fitted to prevent the operator shifting from a forward speed into the reverse when the use of the latter is not desired.

The selective quadrant is not always H shaped, some being similar to a slot, but the movements in changing speeds are the same. It is customary to mark the positions or speeds upon the quadrant and it will be noted that the location of these varies; that is, the same relative movements of the lever will not bring about the same changes of gears on all machines.

One of the earliest practical forms of sliding gear mechanism was the progressive, which derives its name from the fact that in advancing from the low to the high, or in reducing from the latter to the low, one must go through the different speeds. If in the reverse, the low and intermediate must be gone through to reach the high or direct.

A conventional type of progressive gearset is depicted at Fig 70, and it will be noted that the design makes for simplicity inasmuch as the shifting mechanism consists of a single yoke operating in conjunction with a shifting rod. The gears are enclosed as are those of the selective type, in a box or housing which is constructed so that the upper half may be removed, and these cases are provided with inspection or handholes for the purpose of replenishing the supply of lubricant.

Two shafts are mounted so that they revolve freely, the mainshaft being a compound while the other or layshaft is a simple member. The mainshaft is square in form, is connected with the clutch member and rotates when the clutch is engaged. Gears A and B, Fig. 70, move freely upon this shaft when actuated by the yoke, but unless one of these gears is in mesh with another on the layshaft, or the member A is moved so that the high or direct drive is brought into use, the shaft will remain stationary when the clutch is disengaged.

The layshaft, which is a round member, carries four pinions and it will be noted that these are of different size. The smallest of these is constantly in mesh with the largest gear in front of the pinion member and these are known as the constant mesh gears, their function being the same as those described in the selective type of gearset. All pinions on the layshaft are fixed members; that is, they cannot rotate without correspondingly moving the shaft. When gears

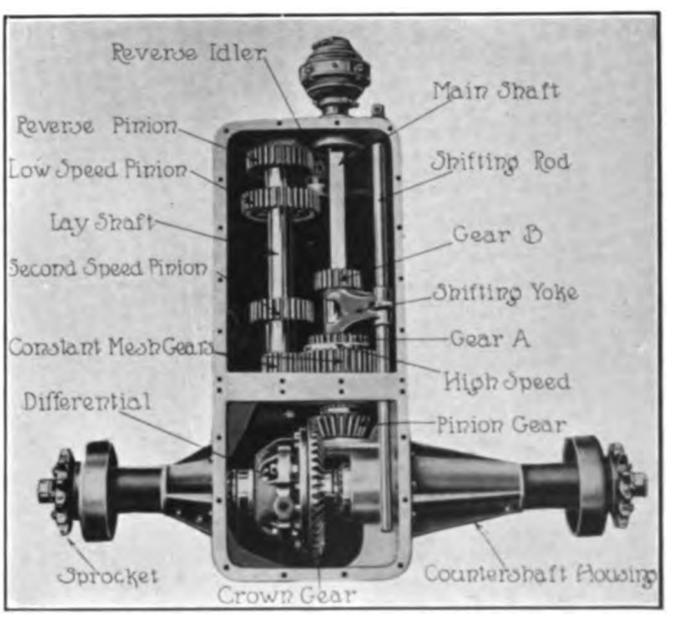

Fig. 70—Outlining the Components of Progressive Form of Gearbox.

A and B are so located on the mainshaft that they are not in mesh with any other pinion or the high speed is not engaged, a neutral position is brought about, and when in

Digitized by Google

this position the clutch may be let in without imparting movement to the countershaft and thence to the driving wheels through the pinion and crown gears.

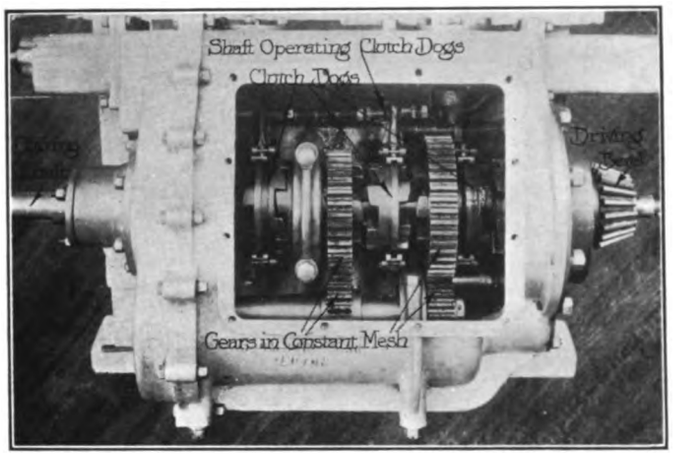

Fig. 71—Transmission of the Constant Mesh Gear Type in Which Changes of Speed Are Effected by Clutch Dogs.

Assume that the car is standing still, the clutch is disengaged, and the lever in the quadrant is in neutral position. To bring about an engagement of the low speed, the lever is moved forward until the first speed notch is reached, which movement slides the yoke and gear B along the mainshaft until the gear meshes with the low speed pinion on the layshaft. The clutch is then let in, and the mainshaft revolves, turning with it the gear B which in turn imparts motion through the low speed pinion and the layshaft revolves as does its constant mesh gear. The latter being permanently engaged with the other constant mesh member rotates this, which is connected to the pinion gear, imparting motion through the crown gear and countershaft to the road wheels.

To change to the second or intermediate speed, the clutch is released, and the lever moved backward into the second speed stop. This movement slides the gear A into mesh with the second speed pinion and motion is imparted to the road wheels by the same process as with the low speed. In changing to the direct or high speed, the lever is moved into the third speed notch which movement slides gear A and the positive jaw clutch into engagement. The mainshaft is then rotating at engine speed and the reduction between the speed of the motor and road wheels is obtained by the gear ratios of the pinion and crown members.

To bring about a reverse movement of the machine, the gear shifting lever is moved to the reverse notch, which brings gear B into mesh with the intermediate reverse idler, and when the clutch is let in the idler member will rotate in a direction opposite to that of the mainshaft. The idler being in mesh with the reverse pinion the latter will revolve the layshaft on which the constant mesh gear will rotate the other constant mesh member in an opposite direction, bringing about a backward movement of the vehicle. In changing from the reverse to the first speed, and thence to the high, the different gears must be meshed, as previously explained.

At Fig. 69 is shown the gear shifting lever, also the brake member and the quadrant with the notches clearly outlined. It will be noted that the gear changing member is fitted with a toothed member, actuated by a spring, the object of which is to hold the lever in the position set. A rod connects the notch member and is pivotally mounted to a handle for the purpose of releasing the tooth when a change of speeds is desired.

Other forms of transmissions are utilized in addition to those of the selective and progressive types outlined. At Fig. 71 is presented a gearbox of the constant mesh type for which many advantages are claimed, among these being an even distribution of the load around the shaft and the eliminating of danger from stripping teeth through careless operation. With this type there are two sets of gears in constant mesh and the mainshaft is provided with clutch dogs of sturdy construction and high grade material. These dog members are shifted into and out of engagement and when one is locked or meshed with a gear imparts motion to the pinion with which it is constantly meshed. Changes are effected by a lever and this type of transmission is made in the selective form; that is, the operator may change from one speed to another without going through the intermediate speeds.

A selective clutch patented transmission is depicted at Fig. 72 and with this type the gears are constantly in mesh. Any desired speed may be obtained by the operator by movements of the controlling lever actuating a clutch, which in turn slides a gear into engagement with a similar member.

The mainshaft is a squared member and carries a number of movable gears or clutches. It will be noted that gears B, C, D and E, are in mesh with other members directly opposite, and that between the gears on the mainshaft are a number of smaller members. The male clutches at W operate on the squared portion of the mainshaft in either direction, and mesh in the female clutches at O O O O which movement in turn drives the constant mesh gears. As a large number of teeth engage at the same time it is obvious that the load is distributed and stresses reduced to a minimum. On the high speed, the male clutch A releases from the female inside B, leaving gears C, D and E idle, and drives directly through the mainshaft to the differential.

As gears and clutches are subject to heavy stresses they are constructed of a high grade steel and cut accurately by special machinery. The edges of the gears in the sliding type are chamfered to facilitate their meshing. Roller and ball bearings are utilized; that is, the shafts revolve on these members, which operate in a bath of heavy oil or lubricant. The gearboxes are constructed dust proof and the halves machined carefully so that an accurate fit is ob-

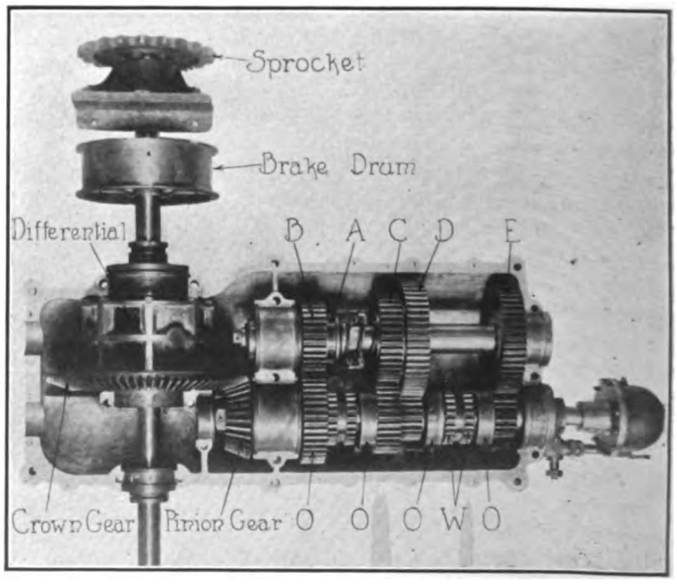

Fig. 72—Another Form of the Constant Mesh Gear Transmission of the Selective Type.

tained, thus preventing the escape of the lubricant.

In some designs the gearbox and differential housing are constructed as a unit, as shown at Figs. 70 and 72. In

Digitized by Google

the former the housing is separated by a partition, an arrangement which provides for the use of a different grade of lubricant in the gearbox and for the differential gears.

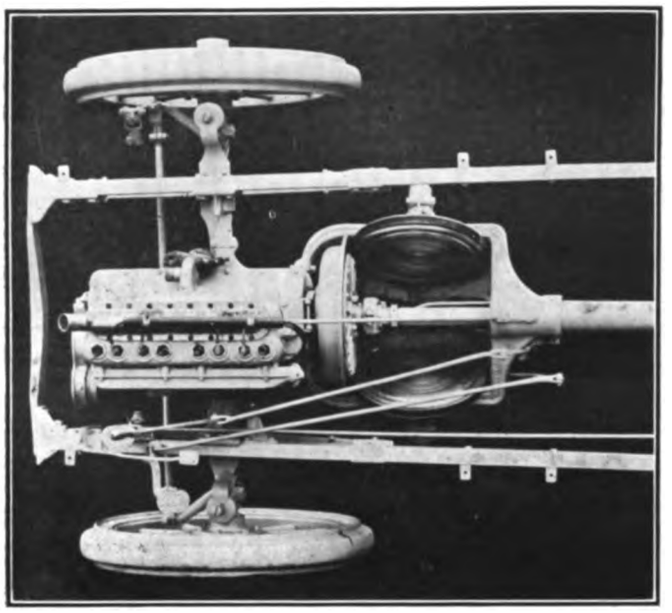

Fig. 73—Friction Transmission Utilising Discs for Low and Reverse—The Clutch Is Shown in High Speed.

Where the final drive is by chain, the transmission and differential are employed as a unit as indicated.

Where shaft drive is employed, or an internal gear drive on the rear wheels, the gearbox is usually located amidships, although it may be placed on the rear axle and made a part thereof. Gears are not wholly employed in the constant mesh type of transmission as chains may be used. This form is growing in popularity abroad where the silent chain drive is being utilized on many leading mechanical transports.

Mention has been made of the friction transmission in which energy is imparted to the driving wheels by a disc in contact with a similar member integral with the flywheel of the motor. At Figs. 73 and 74 are presented a form of friction transmission that is unique, inasmuch as it is employed only in bringing about the low speed and reverse ratios. The direct or high speed is secured by a cone clutch which differs only from those of the usual form in that it may be moved from contact with the female member or flywheel to a considerable distance. This is necessary in order to permit of the operation of the friction discs; that is, to bring about the low speed and a reverse movement which are obtained by moving the cone member forward or back as necessary.

The friction member is clearly depicted at Fig. 74 and in engagement with the other discs. The former is slideably connected with the propeller shaft and is moved forward or backward, being operated by a lever convenient to the driver. In practise the clutch is held out in starting and a feature of the transmission is that the driving discs are stationary when not in operation. That is, they do not revolve when the high speed is being utilized, as the cone clutch engages with a similar member in the flywheel moving the latter away and out of engagement with the pair of discs. When the clutch is released for a neutral effect, by a pedal, the flywheel member does not come in contact with the discs until the operator moves the controlling lever. When the latter is operated and the clutch let in, energy is transmitted through the driving discs to the driven disc.

An innumerable number of ratios is obtained. When the driven disc is near the centre a very low speed or reverse is obtained. This ratio is increased by moving the driven disc toward the periphery of the driving members. At Fig. 74 is shown the discs in engagement for the reverse and as the centre disc is near the centre of the driving members a low ratio will be obtained.

If the driven disc be carried forward of this centre position, a forward speed will be produced, the ratio being determined by the position of the driven member; that is, the nearer to the flywheel, the greater the speed. This forward and reverse movement is brought about by the driving discs, which rotate in opposite directions.

(To Be Continued.)

Ed. Note—The next installment will deal with the differential and the different methods of transmitting power to the driving wheels.

FALL RIVER TO BUY AMBULANCE.

Fall River, Mass., has decided to follow the example of other progressive cities in adopting the automobile for municipal service. It was voted recently to purchase an ambulance, and $4000 was appropriated for this purpose.

JARVIS-HUNTINGTON'S GUARANTEE.

The subject of the written guarantee supplied by manufacturers of commercial vehicles when making a sale is one which interests prospective purchasers, and to which many makers have given extended consideration. The Jarvis-Huntington Automobile Company, Huntington, W. Va., maker of the Jarvis-Huntington line, has given the matter very careful study, and has formulated a guarantee which it believes will make a decided appeal to those who are interested in the purchase of automobile equipment. It reads as follows:

"We guarantee our trucks against defective material and workmanship for 10,000 miles, to the extent that we will furnish, free of charge, new parts in exchange for defective parts, provided said defective parts are returned to us, charges prepaid. This guarantee does not apply to tires,

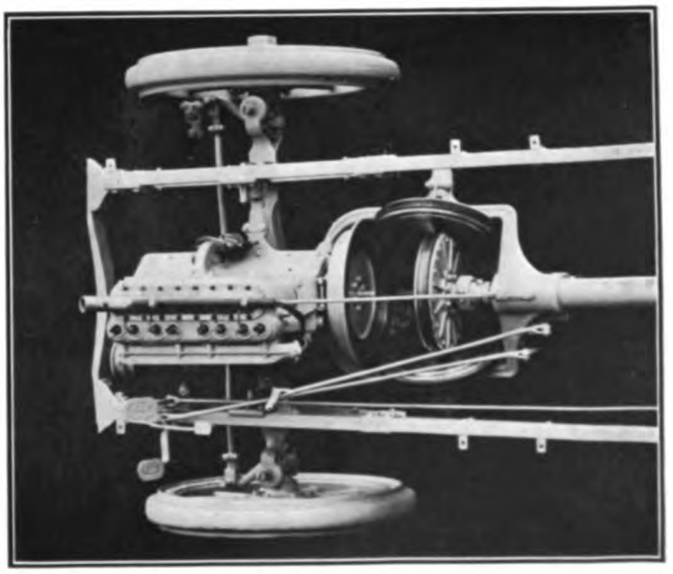

Fig. 74—Friction Transmission, Depicting the Driven Disc in Position to Obtain a Backward Movement of Vehicle.

electrical equipment, wear and tear, accidents or misuses of truck.

"JARVIS-HUNTINGTON AUTOMOBILE COMPANY."

KISSELKAR TRUCK IN NOVEL USE.

Commercial vehicles are put to many uses among which may be mentioned that of hauling supplies and transporting the products of the farm to the railroad, etc. In breaking the ground, however, a tractor usually is employed, but Orlando Moore of Visalia, Cal., has adapted his three-ton KisselKar truck, made by the Kissel Motor Car Company, Hartford, Wis., to this work. He fitted the rear wheels of the machine with flanges, as will be noted in the accompanying illustration, and with these devices obtained traction enough to haul a 24-double-disc cultivator in front of a 12-disc seeder. The machine is utilized for plowing, seeding, cultivating, etc., and in addition hauls supplies and performs all work formerly done with horses.

The vehicle is equipped with a four-cylinder, four-cycle, water-cooled motor having a 4.875-inch bore and five-inch stroke, rated at 50 horsepower. Ignition is by a high-tension magneto and lubrication is by splash. A leather faced cone clutch is utilized and the transmission is of the selective type providing four speeds forward and reverse. Final drive is by chain and a differential lock is fitted. Solid tires are employed, the front members being 36 by four inches, single, and the rear are dual of the same size. Two sets of brakes are provided, internal on rear wheels, and external on jackshaft. The wheelbase is 144 inches and the space back of the driver's seat is 12 feet 3.5 inches.

KisselKar Three-Ton Truck Utilized by Orlando Moore of Visalia, Cal., for Plowing, Seeding, Cultivating, Etc.—The Rear Wheels of the Machine Are Equipped with Flanges to Provide Traction.

WAR DEPARTMENT BUYS MAIS TRUCKS.

The United States War Department has placed an order for four Mais trucks, made by the Mais Motor Truck Company, Indianapolis, Ind., and has sent a squad from the ambulance corps to the factory. The soldiers will be instructed in the care and maintenance of these internal gear driven machines which will be utilized for field duty service at Washington.

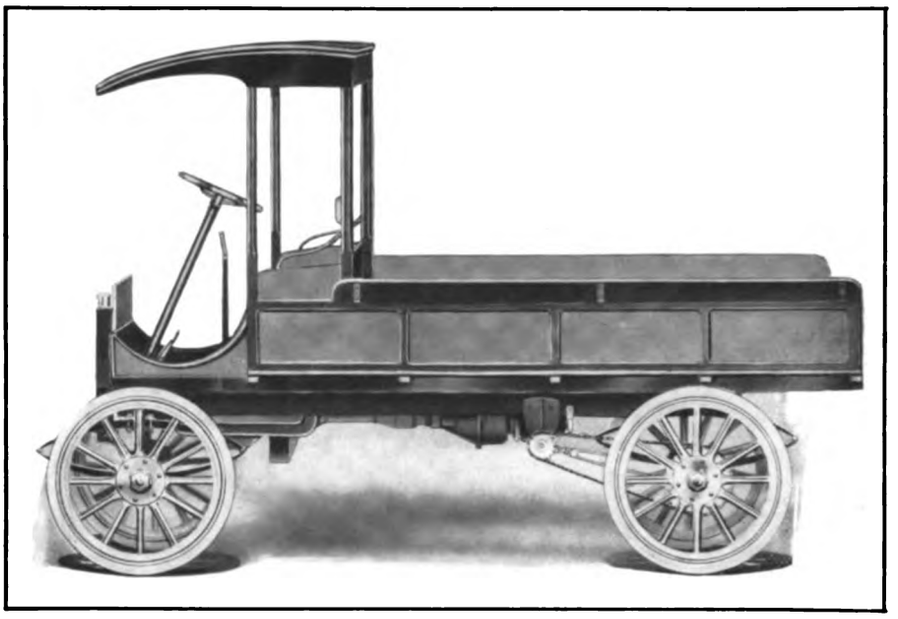
The trucks are practically completed and have been constructed sturdily and in keeping with the requirements of the government, being equipped accordingly. Large wheels are fitted, these being with five-inch dual tires. The bodies are provided with adjustable seats so that they may be used for carryalls about the forts or for ambulance duty. The litters are suspended from the roof of the car by straps.

G. M. C. EDUCATIONAL CAMPAIGN.

Gleeson Murphy, vice president of the General Motors Truck Company, Detroit, left that city recently for a trip to Boston, New York and Philadelphia, where he will hold conferences with the selling representatives of the company. The Detroit concern is promoting an educational campaign and is planning to give every manager and sales agent a complete knowledge of the responsibility, permanency and manufacturing scope of the company, and to this end Mr. Murphy will give a series of talks at each point visited. He will also touch upon local conditions and discuss other features of interest to the branches.

He will be followed by expert engineers in both the gasoline and electric field, who will discuss the G. M. C. trucks and give such technical information as will enable the salesmen not only to become more proficient in talking about the various models, but a better understanding of transportation problems as they affect individual companies. The service system of the company will also be discussed. This is an important branch, analyzing as it does, the needs of any business and making such transportation recommendations, either gasoline or electric, as are best adapted.

The engineering corps will be followed by representatives of the sales department and other business authorities who will discuss branch management and salesmanship. This series of talks is intended not only to bring the various branches together in better understanding, but enable the agents to discuss transportation problems with prospective purchasers.



ADD TO 'BUS LINE.

The North Shore Transportation Company, which operates motor vehicles between Lynn and Swampscott, Mass., is having another machine constructed to go into commission in the spring. The company, which was incorporated last January, comprises Patrice Theriault, Eben B. Phillips and James J. Liffin. The concern intends to experiment with pneumatic tires on the front wheels of the new vehicle and cushion members on the rear. The 'bus now in service averages about 1000 miles a week, it is said, between the towns mentioned.

AVAILABLE WAGONS FOR LIGHT DELIVERY.

LIGHT delivery wagons, ranging from 1000 to 2000 pounds capacity are meeting with decided favor in all sections of the country. Their size is such as to make them particularly adaptable to many lines of business. It would appear that the manufacturers realized this, in view of the large number of such machines which has been placed upon the market within the past few months.

Available Light Delivery Wagon Fitted with Flare Board Body.

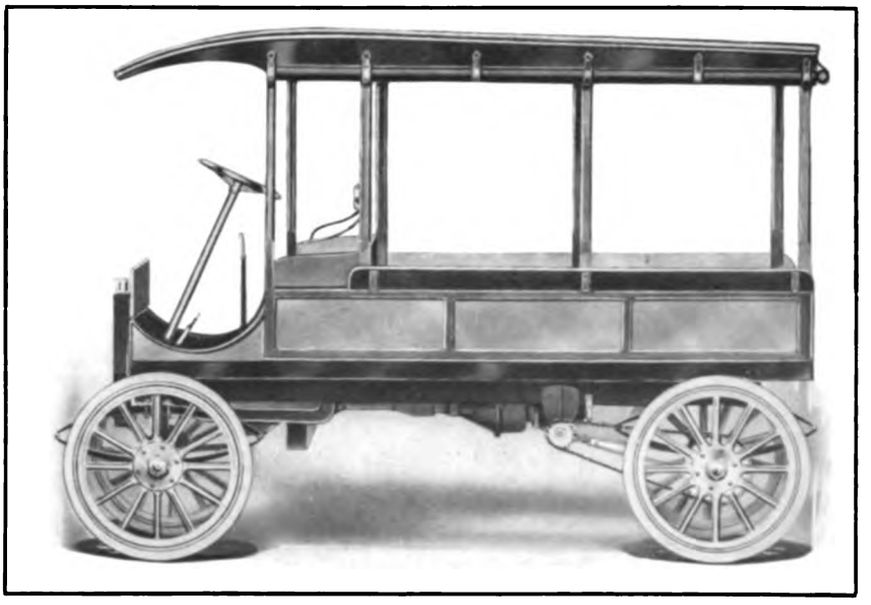
Among the latest productions of this character is the Available, made by the Available Truck Company, Chicago. This is manufactured in two sizes, of 1500 and 2000 pounds, respectively, and with a wide variety of body designs. Accompanying photographs present the two chassis, one fitted with flare board body and the other with open grill.

The maker has paid particular attention to the power plant, which may be conceded to be one of the important features of any motor vehicle. In both wagons, the motor has been designed for the work which it is called upon to accomplish, and no pains have been spared in carrying out this idea.

In the smaller car, the motor has a bore of five inches and a stroke of four, being of the water-cooled, two-cylinder, four-cycle type. The connecting rod bearings are of brass, babbitt lined, while the other bearings are of Parsons' white brass. The material is such as is calculated to make for long life and efficiency.

The oiling system comprises a reservoir of 2.5 gallons capacity, located in the crankcase. The lubricant is circulated by means of a centrifugal pump driven by the camshaft. The entire system has been tried out under exhaustive tests and is held to be thoroughly efficient.

In keeping with the demand for some method of regulating the speed of the truck in the hands of the operator, a centrifugal governor is fitted, this being directly connected with the butterfly valve in the intake manifold just above the carburetor. When this is set to any certain speed, it is impossible for the driver to exceed this limit, without knowledge of the owner.



The radiator is of the square tube type, extra large, and is guaranteed to keep the motor cool at all times. The drive is by shaft to the jackshaft, thence by two Diamond roller chains to the rear wheels. The transmission is planetary, and is a unit with the jackshaft. Both sets of brakes are located in the rear wheels, the emergency members being of the expanding type and the service, contracting.

Wheels are 34 inches in diameter, fitted with solid rubber tires. An option in tire size is permitted, being either two or three inches in cross section, depending upon the load to be carried and the desires of the purchaser.

The one-ton model is very similar in design, but is made heavier in almost every respect. The motor has a bore of 3.25 inches and stroke of four, employing the same circulating oiling system and centrifugal governor. The brakes consist of 10-inch service members on the jackshaft and 12-inch emergency brakes on the rear wheels. A similar tire choice is permitted, the cross section being from 2.5 inches to four. The wheelbase of this model is 108 inches. The maker has found that the larger wagon makes a decided appeal to furniture concerns, and has arranged to provide a standard body for this work. This has a loading space of 44 by 108 by 24 inches, with a 22-inch tail gate, which extends the available loading space to 10 feet 10 inches.

WILL REPRESENT ROWE PRODUCT.

The Rowe Motor Truck Company, Coatesville, Penn., which made initial display of its Rowe trucks at the recent Grand Central Palace show in New York City, announces the appointment of George I. Pound as general eastern sales manager, with temporary headquarters at 327 East 84th street, New York City. The company anticipates a successful season's business, particularly in the East.

ECONOMIC METHODS OF COAL TRANSPORTATION.*

Relation of Proper Loading and Unloading Facilities to the Maximum Efficiency of Mechanical Transports.---Suggestions for Reducing General Operating Costs.

By William Kennedy, Consulting Engineer.

IN ATTEMPTING to supersede horse equipment in the transportation of coal with motor trucks the vital question is whether the conditions of operation can be so modified as to permit of applying the machine to such an amount of its capacity as will reduce the present cost with horses. In other words, there is no question that, if conditions are arranged so that the machine can be permitted to operate for a sufficient period of the working day, it will readily effect a saving.

There are at present many impediments to such machine employment, due largely to delays incident to making the delivery as well as the delays quite frequently experienced in loading at the coal yard. Unloading conditions present the greatest difficulties because they are usually beyond the control of the operators, but the yard conditions being absolutely in the hands of the coal operators, there should be no reason why the loading of coal cannot be accomplished with very short delay to the machine.

Mr. Kennedy Considers Loading by Means of Overhead Hoppers to Be the Ideal Method.

Another important consideration is that unless the loading and unloading of the coal is performed by mechanical means it is difficult to show a saving, unless the distance over which the coal is transported is sufficient to make the speed of the truck effective as a saving. The dependence upon any hand method of loading and unloading is prohibitive.

Another impediment is the fact that the transportation of coal is a seasonable performance and the long months of inactivity, as well as the difference in volume of business between the mid-winter conditions and the periods of lesser activity at the beginning and end of the season, make it somewhat difficult to decide upon an equipment which will be large enough to take care of the maximum conditions and yet will not involve too much investment for the average or normal conditions, and further, the possibility of selecting an equipment of such character as to permit of its use in other lines of service when not required for coal transportation.

Relative to Loading Means.

That the difficulties referred to with regard to loading operations can be changed to provide for quick loading by mechanical means is quite apparent from the number of coal yards which are equipped with hoppers and other mechanical devices which provide for quick loading of the coal, but where such equipments are not in existence the coal dealer has not only the consideration of purchasing an expensive equipment of automobiles, but frequently in addition an expensive modification of his yard facilities.

It goes without saying that the ideal way to load motor trucks would be automatically from the hopper system, the machine passing under the hopper and taking its load in a very few minutes and immediately starting upon the delivery. If this hopper equipment be not in existence the most inexpensive solution of the matter of lessening the delay in loading would be to employ extra bodies, which might be loaded in the absence of the machine and which could be quickly mounted or demounted by the power equipment of the machine itself. This plan might avoid the necessity of any serious change in yard equipment and the cost of loading by hand would not be a serious consideration when contrasted with the investment necessary for mechanical loading. Several plans already have been employed by which separate or spare bodies are utilized in this manner, the body in some cases being hoisted vertically off the truck and held in a suspended position while being loaded until replaced on the machine again for delivery.

Provisions for Unloading.

In making deliveries of coal such a variety of conditions are encountered as to make it often difficult to determine whether the automobile body should be stationary with end or side inclined chutes; whether it should be a body capable of being lifted vertically, or whether it should be tilted at one end or possibly tilted and the body dumped to the ground as is occasionally necessary in handling soft coals. All these types of body equipments on machines are in use, as well as the scheme of handling a large quantity of coal on the semi-trailer equipment, which has the advantage of transporting the greatest portion of the weight over ordinary large diameter wheels with steel tires, but the final determination as to what class of body will be selected must be determined by the particular operating conditions for which the machine is intended.

It is certain that larger loads of coal can be transported by machines than by horses, and in very much less time, but sometimes the delivery conditions of the operator pre-

*Paper read before Retail Coal Dealers' Association of New England, at Boston, March 14.

Digitized by Google

vent him from utilizing the larger sizes of machines in view of the fact that his deliveries are to be made in smaller quantities. Such a case as this is coped with by the employment of a large machine with several compartments in the body so that any one of two or three portions of the load may be discharged without interfering with the balance.

The problem, therefore, is not whether coal can be transported more cheaply by machines than horses, but whether the existing conditions in any particular case will permit of the employment of the machine to anything like its economic capacity. Sometimes these conditions are unchangeable, and again slight modifications or changes only are necessary in bringing about new conditions which permit taking advantage of the machine's utility.

In many cities coal has to be delivered in the most inaccessible places; sometimes to very small manholes at the edge of the sidewalk, sometimes through openings which are located at the building rather than at the edge of the walk, and in other instances into openings which are in the walls of the building above the walk. It seldom happens, except in industrial institutions, that the coal can be directly unloaded below the place on which the machine stands. Wherever these conditions can be changed so that an inclined inlet or chute can be provided from the machine to the coal pile the quick discharge of the coal from the machine can be accomplished, but this is frequently impossible, and in some cases a form of chain bucket conveyor has been fitted to the machine so that the load may be transferred in this manner to points which are otherwise inaccessible.

Two Types of Coal Bodies in General Use, That at the Right Being Designed for Side Delivery and That at the Left for End Dumping.

Cost of Transportation.

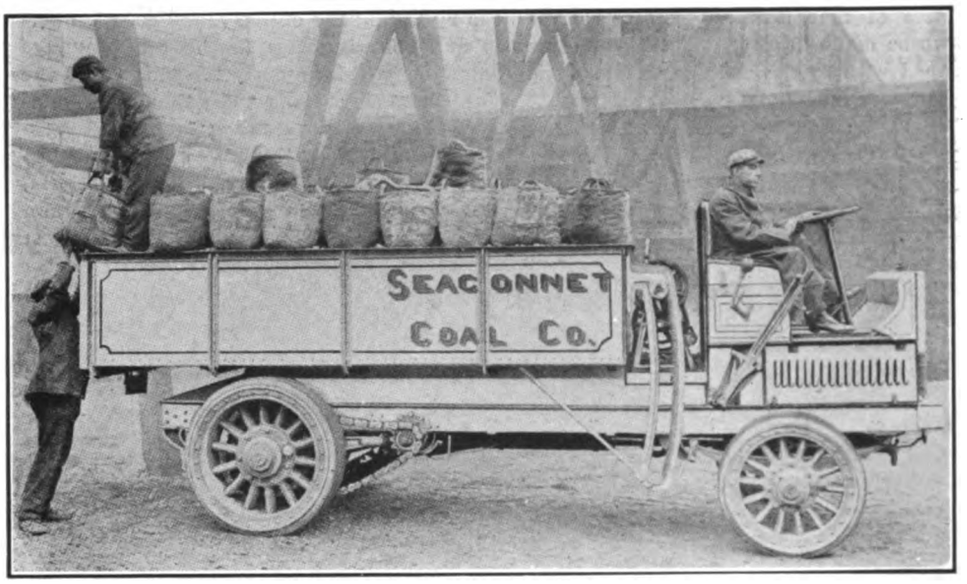
In the matter of securing from coal operators reliable information on the cost of transportation with horse equipment there appears to be considerable difficulty, due principally to the variety of bookkeeping methods, wherever they exist, and the lack of any uniformity in cost a ton or other unit delivered is due to consideration which must be given to the complete inactivity of the equipment during a portion of the year and the variance of activity from one end of the busy season to the other.

Some installations require the maintenance of the horse equipment during the entire year, due to the difficulty found in the selling and replacement, but quite frequently the expense of this all year maintenance is reduced by pasturing the horses in the inactive period. In other cases the horse equipment may be hired out for their service, but in few cases is there any provision for the employment of the vehicle equipment during its inactivity.

The only safe and general way by which the cost a ton can be arrived at is by taking the entire year's cost of operation and upkeep and charging this to the total tonnage transported annually, but we frequently find that only the current charges for the daily operation of the horse vehicles when in active service are charged against the transportation for the current day, and this data alone is the one with which machine operation is compared. Again, we find the reverse condition, as where an installation may be active 26 weeks of the year, while the total cost of the year in bulk is divided by 300 to arrive at the cost a day and this cost a day used as the basis of determining the cost a ton delivered for any day of the 26 weeks. As a matter of fact, the annual cost in this instance should have been divided by 150 to determine the cost chargeable to each active day, and on this basis the cost a ton would be twice that of the former.

Variable and Constant Changes.

The whole problem requires segregation of those charges which are constant whether the vehicle is employed or not, and an additional charge for those items affected by activity added to the first or fixed charge so as to arrive at a true cost of unit performance, whether this latter be based on a tonnage rating or on a ton-mile basis. It is quite possible in determining the operating cost of machines to follow a similar practise of separating the inactive or constant charges from the active charges and the total charge per day thus arrived at should be used in the determination of the cost of delivery per ton or per ton-mile.



To exemplify this the attached table may serve to show the charges influenced by service or inactivity. The items marked "variable," however, are dependent upon each operator's particular condition and to cover charges for garaging and for operators we have assumed a figure of $60 a month for garage and $20 a week for labor. This table with the total figures shown is intended to cover a year's operation and a performance of 50 miles a day a vehicle.

How Table Is Compiled.

In this table it will be observed that on each size truck there is a figure for fixed charges, which includes interest at six per cent. and a depreciation of 10 per cent. on those parts of the vehicle which are not subject to wear and which are replaced or renewed under the heading of maintenance. Under the maintenance charge there is a figure for the upkeep of mechanical wearing parts and another for tires, and in the operation division there are figures covering consumption of gasoline and lubricating oil, operators and other incidentals to the cost of service.

Assume that we are to determine the cost of operation of a five-ton truck which is employed the entire year. The items for fixed charges, garaging and operators are constant

Digitized by Google

Type of Tilting Body, Arranged for Rear Dumping and for Carrying Complex Loads.

and independent of the tonnage or mileage performance of the vehicle. This charge against the vehicle while inactive will amount to $7.56 a day, assuming 312 working days to the year, and the total of the maintenance items, together with the items for fuel and lubrication, can be resolved into a cost of 11 cents a mile, since this example is intended to cover a 50-mile performance each day for 312 days.

Now, with the inactive charge of $7.56 a day and the charge of 11 cents a mile, by multiplying the latter by the mileage performance of the truck on any particular day and adding it to the inactive charge of $7.56 a day we get the total cost for transporting the day's tonnage and in this manner arrive at the actual cost a ton.

Assume that the truck covers 33 miles and delivers 31 tons. Thirty-three multiplied by 11 cents a mile equals $3.63, the active charge, and this added to $7.56, the inactive charge, makes the total cost of the day's performance $11.19, and since this day's performance is the delivery of 31 tons, we divide this figure by 31 and find that the cost a ton is 36 cents. In a similar manner any other performance can be calculated.

In the event of the machine being used only half of the year the fixed charge of $7.56 would be reduced by 50 per cent. of the annual charge for operator and a reduction of the garaging charge during six months to say $5 a month, thus making the fixed charge for the days the machine is rendering service $4.93 instead of $7.56, and consequently, reducing the cost a ton in the particular case cited to 27 cents instead of 36 cents.

If for comparison against such machine cost we have a definitely known cost of transportation a ton with horses, it is quite possible to determine the performance limits of the mileage and tonnage which the machine must accomplish to equal or better the horse cost.

Independent of the higher charges for interest and depreciation which must be made against the machine equipment, it must be recognized that whenever this machine equipment is not being used all the other charges against it cease, with the possible exception of storage, while this is not the case with the horse equipment, which must be fed and cared for almost independent of the service rendered, so that if the machine equipment were not used for six months of the year there might be a considerable reduction in expense over that required to maintain the horse equipment during the same period.

Finally, it should be borne in mind that if there is a long period where the machine is not required for coal transportation and the operator maintains his own garage, it will be quite possible to rent such an equipment at profitable figures in other lines of service, and while assuming control of the garaging and maintenance of the vehicles the owner takes little risk or hazard in leasing the vehicles for such extra service.

It can be readily assumed that such service can be leased at a profit and if this profit is credited against the winter performance cost of the equipment in delivering coal the inactive months of the coal business may thus be made a benefit rather than a detriment to transportation cost by the employment of a motor truck equipment.

GENERAL ANNUAL AVERAGE OPERATING COSTS.

Machine Size	2-Ton	3.5-Ton	5-Ton	6.5-Ton
Fixed Charges—				
Interest on investment @ 6% and depreciation on non-wearing parts @ 10%	$376.00	$458.00	$600.00	$709.00
Maintenance—				
Wearing parts	346.00	420.00	487.00	495.00
Tires	358.00	519.00	757.00	886.00
Garaging—				
Storage, washing, garage labor, insurance (variable)	*720.00	*720.00	*720.00	*720.00
Operation—				
Gasoline @ 10c a gal.	250.00	300.00	375.00	500.00
Lubricating oil @ 35c a gal.	39.00	75.00	105.00	119.00

KNOX EASILY PAYS FOR ITSELF.

The subject of transportation economics is one which is being studied in all its phases by those who are contemplating the introduction of motor haulage. Assistant Sales Manager Charles F. Barrett of the Knox Automobile Company, Springfield, Mass., maker of Knox trucks, is deeply interested in this matter, and cites at least one instance in which a six-ton vehicle paid for itself in one year.

The owner was a large truck concern in a western city, which had a contract to remove all the city garbage, refuse, etc., three miles outside to a reduction plant in the outskirts. For five years this work had been done with horses, and as the concern was contemplating the installation of mechanical transports, very careful figures were kept of the actual cost of operation, including all items, for use as a future basis of comparison.

To do the work successfully with horses, it was found necessary to employ five two-horse teams of three tons capacity each, four of the teams making three round trips daily, or 18 miles, while one team had to make four trips, or 24 miles. Each of the five teams alternated in turn for the extra trip. This arrangement was found to be the most economical for operation with horses, and the daily cost, including all items, such as drivers' wages, repairs, depreciation, interest, etc., averaged over $6, or a total daily cost for the five teams of about $30.

The company purchased a six-ton Knox truck, fitted with 50 horsepower motor. Very liberal allowance was made for tire repairs, depreciation, wages, etc., and the daily cost figured out close to $15. This single truck was easily able to move the entire 48 tons of refuse in a working day of 10 hours, supplanting the five two-horse teams and drivers. It thus effected a saving of $15 a day, or actually paid its own cost, $5200, in 347 working days.

HORSE REPLACED IN CANADA.

One result of the recent automobile shows in Canadian cities is the increased interest in motor trucks throughout the Dominion. Fred J. Titus of the American Locomotive Company, New York City, maker of Alco cars, recently returned from an extensive trip throughout this district, reporting $71,000 in sales within two weeks. He tells of two veteran horse users who have decided to replace their old equipment with modern motor trucks.

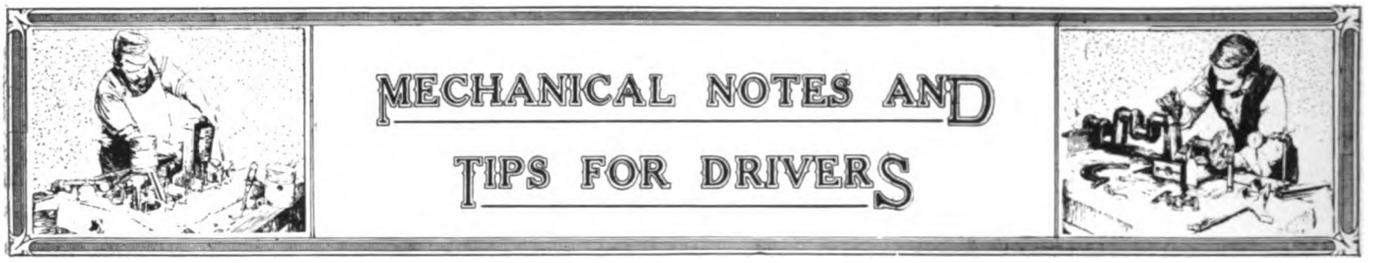
J. B. Smith, head of a large lumber concern, who has utilized horses for 60 years and is famous throughout Canada for the fine type of draft animals in his service, has bought four mechanical transports, which he will equip with hydraulic lifts for moving lumber on and off the vehicles. James Crow, another well known horseman, whose animals have taken many blue ribbons at the New York horse shows, has given up dealing in horses and taken an agency for motor cars and trucks.

Mr. Titus also reports that considerable interest is being taken in an endeavor to use wood block tires instead of rubber. Oak is used almost exclusively in this connection, and the entire country is deeply concerned with the result of the tests now under way.

HARRY W. GRIFFITH PROMOTED.

Harry W. Griffith of Indianapolis, Ind., who has been the secretary-treasurer of the Remy Electric Company, Anderson, Ind., well known maker of ignition and lighting specialties, has been appointed general manager in place of W. R. Poland who has resigned to affiliate with a new company which has been organized in Anderson for the manufacture of self-starters for motor cars. Mr. Griffith has had a long experience in the manufacturing business, having been connected with the American Creasoting Company of Chicago prior to joining the Remy concern. His many friends will be pleased to learn of his promotion.

SHAWMUT TIRES AT BOSTON SHOW.



One of the most educational exhibits among the accessory displays at the recent initial Boston motor truck show was that conducted by the Shawmut Tire Company of that city. At this space was seen the whole process of making tires from rubber. The rubber tree was presented, and the method of sapping it, as well as the large biscuits of pure rubber, the form in which the product is shipped to this country. Shawmut tires also were shown in all the different stages of construction.

ADAMS TRUCK SAVES MONEY.

The Adams Bros. Company, Findlay, O., is in receipt of figures from an owner of one of its one-ton vehicles. According to this statement the truck is doing the work of three two-horse wagons, at a saving in cost of equipment of $442.75, and in operating expense of $2567.98. The actual figures follow:

Investment, Horses—		
Seven horses @ $350 (based on one extra)	$1750.00	
Three wagons @ $275	825.00	
Three double harnesses @ $65	195.00	
Seven blankets @ $2	14.00	
Seven halters @ $1.25	8.75	
Total		$2792.75
Investment, Truck—		
Model A, Adams one-ton truck	$2100.00	
Express body and top, plus freight	250.00	
Total		$2350.00
Saving on investment		$442.75
Operation, Horses—		
Three drivers @ $70 a month	$2520.00	
Stable, feed, veterinary, etc.	2268.00	
Repairs and painting, wagons	135.00	
Repairs, harnesses	24.00	
Interest on investment @ 6%	167.57	
Depreciation on horses @ 16.6%	291.66	
Depreciation on equipment @ 15%	156.41	
Total		$5562.64
Operation, Truck—		
Driver @ $75 a month	$ 900.00	
Helper @ $60 a month	720.00	
Gasoline, five gallons a day @ 14 cents	210.00	
Oil and grease	40.00	
Repairs and painting	300.00	
Oil for lamps and incidentals	20.00	
Tire maintenance	200.00	
Garage	72.00	
Interest on investment @ 6%	141.00	
Depreciation @ 16.6%	391.66	
Total		$2994.66
Saving on operation		$2567.98

REMOVING CARBON FROM CYLINDER.

Carbon deposits on the piston head and in the combustion chamber not only cause a loss of power but an excess of the matter is productive of premature ignition and a noisy motor. Where a large quantity of lubricant is fed to the engine, carbon accumulates very rapidly. It should be removed and the operation does not require the removal of the cylinder as the burnt matter may be cleaned from the head of the piston by utilizing a scraper which may be constructed easily from a piece of .25 or .3125 inch soft steel. The ends of the metal are flattened in a forge and bent hoe shaped, after which the edge is sharpened by grinding on an emery wheel or grindstone.

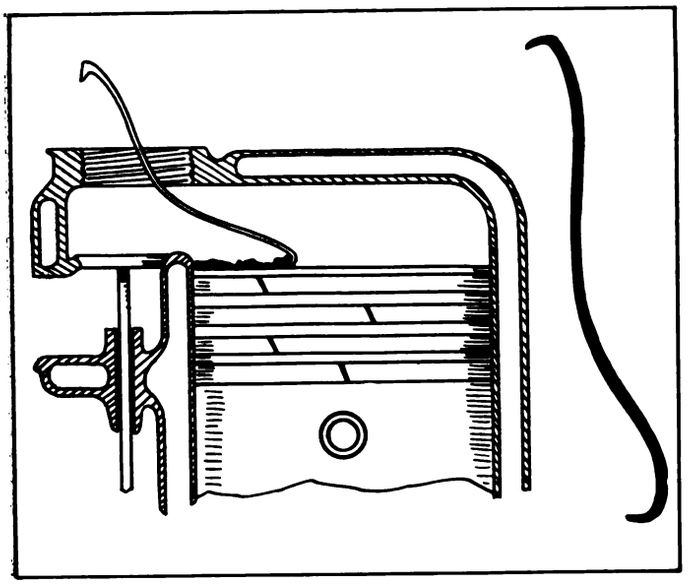

Fig. 1—Depicting How Carbon May Be Removed from Cylinder with Home Made Scraper.

At Fig. 1 is depicted the tool and the method of operation. The valve cap is removed, the piston brought up to the top of its stroke by cranking and the scraper inserted. The latter may be bent to obtain the desired angle, and by means of the sharp ends of the scraper the carbon loosened and removed.

Sometimes it is advisable to remove the cylinders; in fact, many operators who take care of their own machines make it a practise to clean the carbon out of these members at stated intervals, this depending upon the time the car has been in service. The removal of the cylinders is an easy matter but in taking off the rings to get at the carbon back of these members the novice is apt to break the rings, which are brittle.

At Fig. 2 C is shown a method of utilizing old hacksaw blades or smooth strips of metal. Three or four are necessary and these are slipped between the ring and piston proper, as shown in the sketch. This will permit of drawing the rings off without danger of damage. The top ring should be removed first and the remaining members in order. In replacing them, the lower ring should be sprung slightly and slipped over the head of the piston and the blades inserted. The ring is then pushed downward and slipped into the recess. The next ring is replaced and the operation repeated until every one has been fitted.

Care should be taken to note that the openings of the rings do not come in a line. If they are of the pinned type this precaution will not be necessary but otherwise they should be so arranged as to prevent the loss of compression.

Replacing the cylinders will bother the novice and unless care be exercised one or more rings will be broken and the fingers injured. While one familiar with this work can put back a cylinder alone, the amateur repairman should have assistance. With a helper to hold the cylinder and the workman to compress the rings the operation will be accomplished easily.

There are several methods of compressing the rings so that the cylinder will slide over. Some employ a string, but a better method is to make a clamp such as depicted at B. This should be constructed from a piece of flexible metal .125 inch thick and about .5 inch wide. It should be an inch or more longer than the circumference of the piston and when bent into a circle as shown, should be slightly less to enable the device to compress the ring flush with the piston.

To use the tool, it is placed over the top ring, compressed with a pair of pliers and held while the helper slides the cylinder downward, which operation will move the ring holder at the same time, allowing the cylinder to pass over the ring. The operation is repeated until all of the rings are in position. If the operator desires to do this work without assistance, the ends of the holder may be tapped, drilled and fitted with a screw and locking nut. This will enable the workman to clamp the ring so that its upper part is exposed. The cylinder is then slid over until it comes into contact with the clamp. The latter is then released and placed over the next ring and the operation repeated.

TRUING UP COIL POINTS.

To obtain efficiency from a coil it is essential that the platinum points be kept clean as well as that they should seat properly. When these members are so adjusted that the strength of the current is in excess of amount stated by the maker of the coil, the metal will burn or fuse and the surfaces of the points will be pitted and uneven. When these conditions exist considerable more electricity is required to overcome the resistance set up. This not only wastes current but the operation of the motor is affected.

There are several devices for truing up the points, such as jigs, etc. Some utilize a velvet file, but it is difficult to remove the rough places evenly and in addition, a considerable amount of the platinum is likely to be wasted. With the methods outlined it is necessary to remove both the upper and lower parts to do the work properly.

A simple and efficient repair and one that may be made without displacing the parts is shown at Fig. 2 D. It consists of a strip of fine emery paper placed between the two points as shown. The work will require two operations, that of the treating the upper point first, then reversing the paper and smoothing the lower point. The paper should be held perfectly horizontal. The adjusting screw

Digitized by Google

should be turned down so that the points grip the paper slightly. All dust or dirt should be removed after the operation and the units readjusted. To obtain the best results from a coil the tension of each vibrator should be the same, each drawing the same amount of current and this may be brought about by the use of an ammeter.

RADIATOR CAP DEVICE.

The commercial vehicle is subject to constant vibration owing to its being operated over rough pavements, and if the driver is careless in replacing the radiator cap after replenishing the cooler with water, the cover is apt to jar loose and be lost on the road. These members are more or less expensive and to prevent their loss may be fitted with a safety device such as illustrated at Fig. 2 A. These are inexpensive and may be constructed by anyone possessing a slight knowledge of the use of the soldering iron.

A small length of chain is attached to a loop or ring and the latter soldered to the cap. The other end of the chain is equipped with a bar and this should be slightly longer than the diameter of the opening in the cooler. The function of the bar is obvious. When it is dropped into the radiator its length being greater than the size of the opening it cannot be withdrawn while in a horizontal position. In the event of the cap working loose, it will be held by the chain and the attention of the driver will be drawn to the member by the rattling of the cap against the radiator.

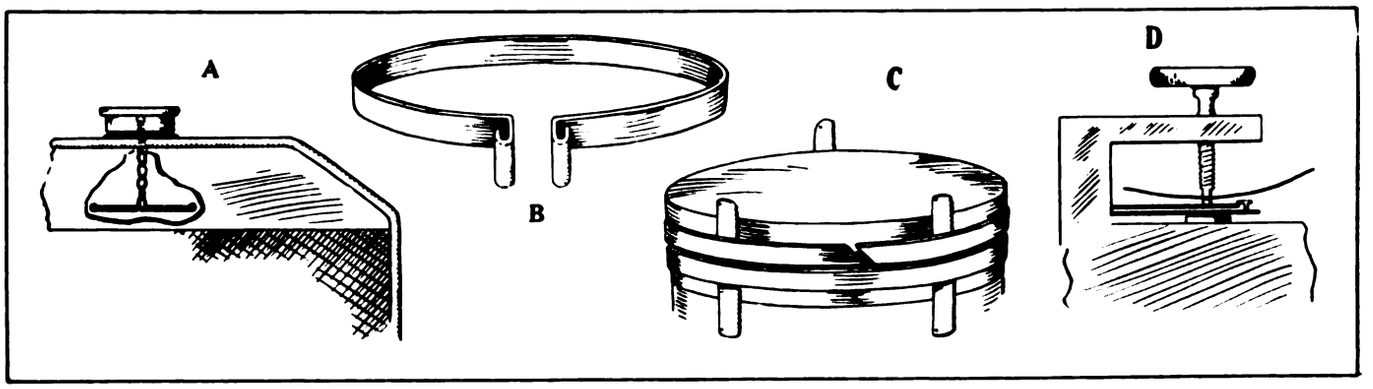

Fig. 2—Some Hints for Operators: A, Safety Device to Prevent Loss of Radiator Cap; B, Piston Ring Clamp; C, Utilizing Old Hacksaw Blades to Remove Piston Rings; D, Truing Up Coil Points with Emery Paper.

STARTING ON MAGNETO.

The majority of commercial vehicles are equipped with a dual ignition system, this consisting of dry cells or a storage battery and a magneto. When the latter is of the true high-tension type care should be exercised when attempting to start the motor with this member. The starting handle should be pulled up smartly, and this should be done with the left hand if the operator be right handed. Some drivers who spin the starting crank make it a practise to push down with the right hand, imparting a rocking motion to obtain inertia enough to swing the handle over, in other words, to overcome the resistance of the compression.

This is dangerous as owing to the construction of the magneto the current generated and built up reaches its maximum at a certain position of the armature and if the starting handle be rocked far enough a spark will cross the gap at the spark plug, exploding the mixture before the piston reaches the top of the compression stroke. The result will be what is termed a backfire and the operator is liable to be injured.

Magnetos are generally so timed that the spark takes place before the piston has reached dead centre and sometimes this advance is more marked. Owing to the fact that there is no lag in the action of the current as with a coil, it is obvious that a backfire is brought about more easily. If the carburetor be adjusted properly and there is no leak in the intake pipes, a true high-tension magneto will start a motor on a quarter-turn of the starting crank.

TESTING EMERGENCY BRAKES.

It is an excellent idea to try the emergency brakes occasionally to note if these members are working properly. Some drivers think that because they hold enough to prevent the car from moving after it has come to rest the brakes are in perfect order. They should be tested while on the road and if they do not grip well should be adjusted. Sometimes the members have been dragging, wearing the lining to such an extent that when the lever is moved the friction set up is not sufficient to check the momentum of the machine.

LIGHT HAMMER BEST FOR RIVETING.

Rivets are commonly used in relining brakes, clutches, etc., and the novice is apt to select a heavy hammer for peining over the head, wondering why he is not successful. The proper tool is a light hammer with which a number of light blows are struck, spreading out the end as desired. If a rivet were held rigidly in a tight hole a heavy blow would expand only the projecting end, but it is not usually so held, and the tendency of the heavy blow is to displace and force apart that which is desired to bring together firmly.

HANDY SPARK PLUG BRUSH.

In cleaning spark plugs it is customary to utilize a brush with stiff bristles and gasoline. These members may be purchased at a supply house and are inexpensive. A handy brush may be made, however, by taking a small piece of .25-inch brass or copper tubing and bristles from an old brush. The bristles are inserted in the tubing and the ends of the latter compressed.

CARE OF LUBRICATORS.

The lubricating system of the motor should be given care and cleaned occasionally. The majority of the makers fit screens for the purpose of filtering the oil and these members become clogged and the flow of the fluid affected thereby. In cleaning the lubricators these screens should be removed and inspected, and if dirty washed with gasoline and replaced at the same time the crankcase is cleaned.

ELECTRIC VEHICLE BREVITIES

During the Chicago commercial vehicle show the Waverley Company, Indianapolis, Ind., received word from its New York representative that an order for 10 light delivery wagons had been placed by the Fleischmann Company of that city. A few days later a repeat order was taken, making a total of 20 contracted for by that company. The order was placed after long experiment with a Waverley in competition with other types of vehicles, and the maker naturally was elated.

The light electrical transport is adapted for the yeast industry, as many stops are made in delivery, and the simplicity and ease of operation appeals to houses which maintain several vehicles for distributing a large number of packages in certain areas.

In the accompanying illustration is depicted one of the cars ordered by the Fleischmann Company and these are manufactured in two models, of 600 and 1000 pounds carrying capacity, respectively. The lighter machine has a length over all of 125 inches with a wheelbase of 87 inches. The inside body dimensions are three by four by five feet. Wheels, both front and rear, are fitted with 32 by 2.5-inch solid Firestone tires. The batteries are constructed in

One of a Fleet of 20 Light Delivery Electric Vehicles Recently Sold to the Fleischmann Company, New York City, by the Waverley Company, Indianapolis, Ind., Through Its New York Representative.

small units making for easy handling and these are the 28-cell type, 13 MV Exide Hycap, the same size Waverley or National. The maximum speed is 15 miles an hour and the mileage on one charge of the batteries from 50 to 80 miles, this depending upon the roads.

The motor is 60-volt and drive is by shaft. A continuous torque controller is utilized with four speeds forward and reverse. Two sets of brakes are provided, both expanding, on the rear wheels and countershaft. Full elliptic springs are fitted both front and rear and the front axle is of the I beam section type while a full floating type is utilized in the rear. The frame is of armored wood, and roller bearings are employed. Control is at the left and the vehicle is equipped with storm front and side curtains with celluloid windows.

The Edison Electric Illuminating Company of Boston is erecting what is said will be one of the largest garages in the country on the old Boston College athletic field on Massachusetts avenue, and the structure is to be a part of the great service plant that the company is building. It will face Massachusetts avenue at a slight angle and will have a depth of nearly 340 feet and a width of 110. The front part will be three stories in height and the rear but one, and these sections will be separated by a wall. Originally it was the intention of the company to utilize the front building for a stable and the rear for a garage, but before ground was broken it was decided to eliminate the horse drawn equipment and employ automobiles.

The front building will be used for gasoline vehicles and will provide accommodations for about 50 cars, it being about 110 by 80 feet. The ground floor will permit of the storage of 30 automobiles and all of the modern facilities for washing, polishing, etc., will be installed. The second floor will be devoted to the use of the drivers and their equipment, and in addition will provide space for about 20 vehicles. The repair and paint shops will be located on the third floor and will be completely equipped for the care and maintenance of mechanical transports.

The electric garage will be 110 feet wide and about 250 feet deep, all on one floor with entrances on the sides and ends. It is stated that four rows of machines may be stored easily besides providing plenty of space for working around the cars. There will be the usual facilities for washing, etc., and modern equipment for charging batteries as well as apparatus for removing and replacing these members.

The stock building of the company is to be located next to the garage on one side and here all supplies except the heaviest will be carried. There will be a street between the garage and stock building and it will be covered with glass, the idea being to make it possible to load the machines with the greatest dispatch, much of the loading being done at night, so that each automobile will be ready for service in the morning.

Four doors in the side of the garage provide means for the machines to run across the street to the loading platforms of the stock building. Beyond the latter will be another structure in which heavy parts will be stored. The group of buildings will be supplied by electricity from a transformer station beyond the second stock structure. Merchandise will be received from the railroad by a spur track. It is expected that the plant will be ready for occupancy late this year.

The Revere Rubber Company, Revere, Mass., is replacing its horse drawn equipment with the more modern mechanical transport and has placed an order with R. M. Thurber of the Boston sales office of the General Vehicle Company of Long Island City, N. Y., for a fleet of 3.5 and five-ton trucks. These will be utilized for transporting heavy loads between the factory at Revere and Boston. Mr. Thurber, who secured the order for which competition was unusually keen, is very much elated with his success in placing electric vehicles.

Announcement is made by the Baker Motor Vehicle Company, Cleveland, O., that William P. Kennedy, the well known consulting electrical engineer of New York City, will act as superintendent of the bureau of service efficiency for that company. Mr. Kennedy has for some time been affiliated with the Cleveland concern as its consulting transportation service engineer. He has had a broad experience and possesses a deep knowledge of the subject.

Digitized by Google

Delivering electric meters in a large city is a difficult and delicate task but the problem of safely transporting these members, which have to be handled carefully owing to their finely balanced mechanism, has been solved by the New York Edison Company of New York City, which concern maintains a fleet of electric vehicles. In the accompanying illustration is depicted three of the numerous cars utilized by this company, and these are Detroits, made by the Anderson Electric Car Company, Detroit.

They are stock models, but an interesting feature of the body construction is the fitting of nests for carrying meters. The latter are injured easily and the company formerly utilized rubber matting to absorb the road shocks and to eliminate vibration which has a tendency to cause the meters to register inaccurately.

The idea of constructing compartments or nests was originated by a member of the meter department who noticed a baker's wagon in which the pies were carried in separate compartments so built that the pastry was held securely. The plan was copied and the bodies of the automobiles were fitted with racks on either side of an alley way. Each compartment was fitted with a cushion which covers the floor and part of the walls and drops over the sill, so that once a meter is placed inside it is safe and secure. Each machine carries 42 of these nests in addition to the equipment for installation.

The New York Edison Company formerly divided the island of Manhattan into three districts with a meter storehouse in each and all meters required were transported from the main station at West 39th street. This system was abolished as were the branches, this being made possible by the use of the electric automobile. The main station was retained and this has a capacity of 20,000 meters, these being transported by the machines, which are loaded in the afternoon and start out the following morning, delivering directly to the different jobs ahead of the wiring crew. This saves considerable time in the installation and the customer is benefited thereby.

The machines employed have a carrying capacity of 3000 pounds and weigh approximately 4500. Edison batteries of nickel and steel construction are utilized, these being free from sulphation, leaky jars, and are not affected by the vibration set up in traversing rough roads. These have 60 cells with the Edison A6 for light and A8 for heavy service. The normal voltage of the motors, which are of the series wound type, is 70, and the normal amperage 48. Hess-Bright annular bearings are employed, and the brushes are well mounted, of special design and liberal area.

The drive of the first reduction is by Renold chain and second by roller chain. The gear ratio is 11.55 to one. A continuous torque drum type of controller is employed, the contact fingers of which are held under tension by laminated springs. The reverse switch is the improved laminated type, mounted with the controller and an interlocking device of simple construction is fitted, preventing the possibility of the driver "bucking" the motor, it being necessary to bring the controller into neutral position before changing the current directions. Oilers are provided at all bearing points.

The brakes are two in number, located on the rear wheel hubs and countershaft, and operated by pedal. The front wheels are 34 inches in diameter and rear 36, these being fitted with Timken bearings and the solid tires are 34 by 2.5 inches front and 36 by four rear. The wheelbase is 96 inches, tread 62 and road clearance 11.5. The overall dimensions are: Length 155 inches, width 74, height 100. The speed an hour loaded is approximately 11 miles an hour and mileage 40 and 55 with the light and heavy service batteries, respectively.

A Sangamo ampere-hour meter is a part of the regular equipment. This instrument is a regular battery gauge, and gives correct information as to the current the battery contains, also affords opportunity for daily records. The new Veeder gearless hub odometer is furnished, also such extras as inspection lamp, tools, etc.

Trio of Detroit Electrics, Made by the Anderson Electric Car Company, Detroit, in Service with the New York Edison Company—The Bodies Are Equipped with 42 Nests for Transporting Meters.

That the electric vehicle is meeting with favor with express companies is noted by the large number of orders being placed with the General Vehicle Company, Long Island City, N. Y. Many of the purchasers repeated their orders and an instance of this kind is noted in the case of the American Express Company, which placed a number of trucks in service at its Boston department. In addition a contract was made with the General Vehicle Company for 25 3.5-ton trucks for the New York branch. This large order was followed recently by another for 20 two-ton and three 3.5-ton machines, which will be utilized in one of the cities. Among the express concerns repeating orders is the Adams Express Company, which recently contracted for a large number of electrics. The New York Transportation Company, which is known to many as Dodd's Express, has repeated its order for three 3.5-ton trucks.

Figures showing the actual performance and cost of

Digitized by Google

commercial vehicles are of interest to those contemplating the installation of the mechanical transport. The Baker Motor Vehicle Company, Cleveland, O., has, through its transportation service department, compiled figures showing the performance of a fleet of eight electrics in service with a large department store. The data comprise a daily chart of the service afforded and its total cost for two months by days, the cost being operating expenses, plus depreciation, insurance, repairs, interest on investment, etc. The months taken were November and December, the former when the machines were operating under normal conditions, and the latter during the holidays. During November the cars averaged 36 miles daily and the average of packages delivered daily was 164, and at a cost of 4.03 cents a package.

During 26 days of service in December the machines averaged 35 miles a day, delivered an average of 247 packages and at a cost of 2.7 cents each. The largest number of deliveries made in one day was 401, and 34 miles were travelled, while the biggest mileage was 50, when but 195 packages were delivered. The figures follow:

Date	Mileage	No. Packages	Date	Mileage	No. Packages
Nov. 1	34	169	Dec. 1	33	164
Nov. 2	37	172	Dec. 2	40	170
Nov. 3	35	153	Dec. 3	47	183
Nov. 4	31	170	Dec. 4	12	142
Nov. 6	45	145	Dec. 5	50	195
Nov. 7	27	208	Dec. 7	34	208
Nov. 8	52	142	Dec. 8	27	227
Nov. 9	33	167	Dec. 9	30	240
Nov. 10	41	130	Dec. 10	41	243
Nov. 11	56	123	Dec. 11	33	198
Nov. 13	34	175	Dec. 12	38	204
Nov. 14	43	150	Dec. 13	30	260
Nov. 15	30	213	Dec. 15	27	314

Nov. 25	34	163	Dec. 27	42	307
Nov. 27	32	112	Dec. 28	45	277
Nov. 28	30	174	Dec. 29	43	209
Nov. 29	26	150	Dec. 30	24	179
			Dec. 31	26	147

Day Baker, New England manager of the General Vehicle Company, Long Island City, N. Y., stated recently that few people in business life realize the volume of business being transacted in the truck line in Boston. He says: "The business public has decided to do its transportation by commercial vehicles, and while the truck is far more economical than any other form of transportation, especially if its form and size be adapted to the particular work, the business man will utilize mechanical transports regardless of the economy of operation. Automobiles are in line with the progress and spirit of the age, and the public is bound to have them, both the electric and gasoline types. The electric vehicle solves the transportation problem in cities and towns, while the gasoline machine is adapted for the long hauls over suburban roads. In cities, the former type is handled more easily and the cleanliness of the electric appeals to many. The recent exhibition at Boston will have a very potent influence upon the commercial vehicle transportation in New England."

Following the example of Boston, the railroad authorities at Springfield, Mass., have decided to try an automobile baggage truck operated by electricity. The experiment proved so successful in the former city that the vehicle was shipped to Springfield for a trial and if it demonstrates its practicability, as it has in a number of cities, will be made a permanent fixture. The machine is known as the double decker type having two surfaces 42 by 85 inches, one above the other on which baggage may be deposited. It has a back which may be used for another extension of the lower plane to a trifle over 10 feet. Its carrying capacity, 2000 to 4000 pounds, is considerably greater than that of the ordinary hand trucks and it has a speed which can be regulated from two to 10 miles an hour.

The Baker Motor Vehicle Company, Cleveland, O., maker of Baker commercial and pleasure vehicles, is issuing a neat folder in colors which depicts a fleet of 50 cars in service with the American Express Company of New York City.

The city of Alliance, O., is a progressive municipality, and conducted a series of experiments with the different types of automobiles to secure a vehicle best adapted for a combination police patrol and ambulance. The committee in charge of the tests decided upon the product of the Argo Electric Vehicle Company, Saginaw, Mich., maker of electric commercial and pleasure vehicles of all types.

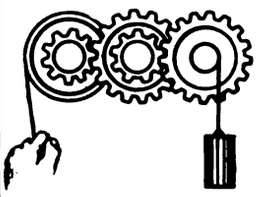
REPEAT ORDER FOR SAMPSON TRUCK.

After experimenting with the motor propelled vehicle for 15 months, the Mosler Safe Company, New York City, has ordered a second machine which will be similar in every respect to the first car. The Sampson power wagon, made by the Alden Sampson Manufacturing Company, Detroit, a constituent of the United States Motor Company, New York City, will be fitted with windlasses operated by the power of the motor, enabling the crews to lift the heaviest safes in much less time than with hand power.

COAL DEALERS DISCUSS MOTOR VEHICLES.

The Maine Coal Dealers' Association held its annual meeting recently, at which the various cities and towns were represented. A feature of the session was the address upon modern methods of handling coal by W. A. Clark, president of the New England Coal Dealers' Association. The practicability of the mechanical transport was pointed out by the speaker, and the various loading and unloading devices outlined.

BARKER HEAVY DUTY TRUCK.



Charles L. Barker, Norwalk, Conn., maker of marine and stationary gasoline motors, is now manufacturing three and five-ton commercial vehicles which are to be known as the Barker Heavy Duty truck. Of the design is emphasized its simplicity, durability and accessibility. The power plant is stated to be sufficient to handle the heaviest of loads. The clutch is a multiple disc and the transmission provides a direct drive on the second and third speeds. Final drive is by chain, fully enclosed. A feature of the design is a dash fuel tank with emergency member.

G. M. C. FOR QUICK TRANSPORTATION.

The keen business man can find many ways of saving time when supplied with the modern motor truck. Gleeson Murphy, vice president of the General Motors Truck Company, Detroit, cites the instance of a contractor in Natick, Mass., who owns a 3.5-ton G. M. C. truck. Instead of waiting for teams to move his tools and other building material, and sending his men on the next job by train, he simply loads the entire outfit into the vehicle and away he goes. Recently, he moved his equipment and men 24 miles and was on the new job in three hours. On another occasion, he finished some work at 2 in the afternoon, loaded his men and tools, shifted to another city 75 miles away, and began work on the new job the next morning at 7.

RECENT MOTOR VEHICLE PATENTS

Hunt Motor Truck.

Charles W. Hunt, deceased, New York City, has been granted a patent for a motor truck consisting of a driving axle and wheels, a carrying axle and wheels and a frame. Motor frame is independent of usual frame member and has a two point bearing on the driving axle and a single point bearing upon the carrying axle, extending beyond the driving and away from the carrying members. The motor is mounted upon the extension and its weight acts upon the driving axle with a minimum leverage.

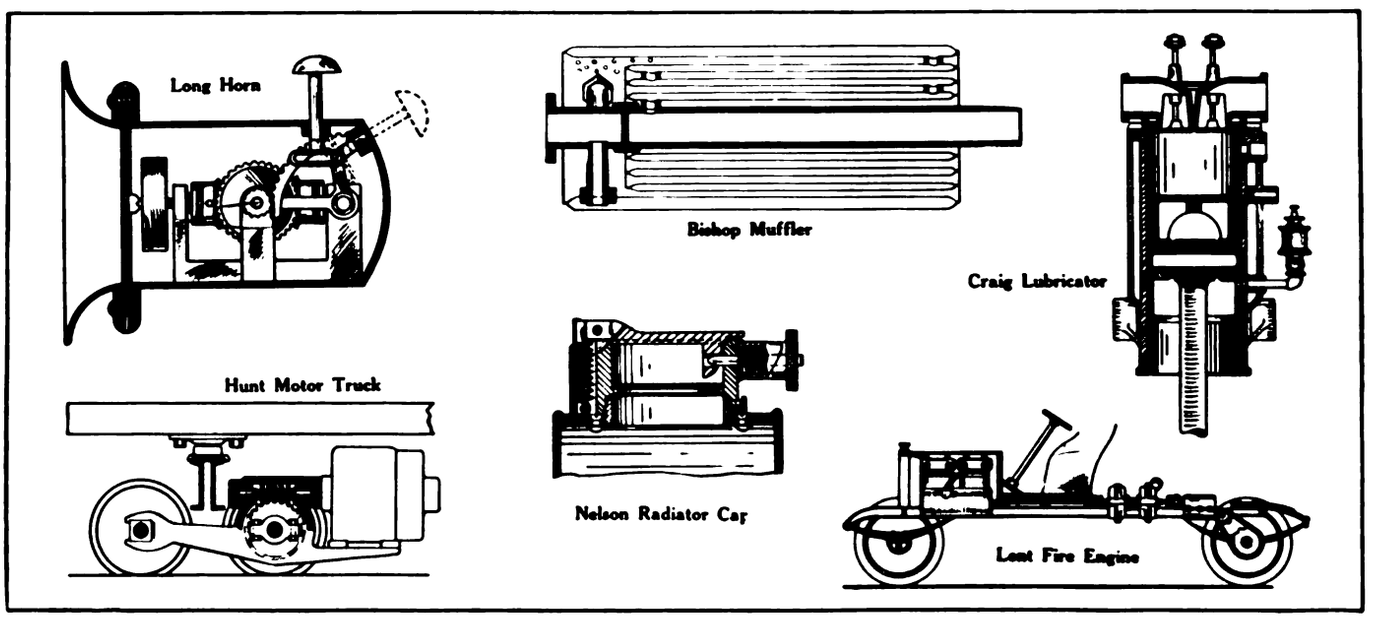
Lent Fire Engine.

An automobile fire engine has been patented by Leon B. Lent, Brewster, N. Y. It is similar to the usual four-cylinder pleasure motor car with the exception that a rotary pump is mounted amidships on the frame. The transmission is fitted between the main driving shaft and rear wheels, and a shaft operates the pump member by a wheel which serves as a flywheel for the motor. The impeller is permanently mounted upon this shaft which also serves as a driving member for the vehicle.

Long Horn.

An automobile horn which is operated by hand has been invented by Robert E. Long, New York City, to whom a patent has been granted. It is similar in shape to horns having a diaphragm and the plunger rod may be fitted at the top or end. When this member is depressed it actuates a gear which in turn operates another toothed member engaged with a number of striking members, these carrying several balls rotatively mounted in perforations adapted to strike on projections rigidly mounted on the diaphragm when a weighted rotary disc in its vicinity is operated.

Bishop Muffler.



George Arthur Bishop, Leeds, England, has been granted a patent for a muffler which comprises a gas inlet pipe surrounded by a series of annular chambers with closed ends and so arranged as to provide cooling spaces between them. Inlet and outlet ports are provided near opposite ends of these chambers, also radially extending tubular distance pieces connecting the outlet ports of the pipe with the inlet members of the first of said chambers, and radially extending tubular distance pieces connecting the outlet ports of each chamber, except the outer one, to the inlet ports of the next adjacent chamber.

Craig Lubricator.

A device for lubricating the wristpin of a piston has been invented by James Craig, New Rochelle, N. Y. Lubricant is supplied by a cup through a passage in the cylinder wall to an annular cavity in the piston. The fluid is led through a port to a groove in the wristpin which is fitted with a chamber and means are incorporated for lubricating the upper and lower surfaces of the pin.

Nelson Radiator Cap.

When an operator of a commercial vehicle is careless in replacing the radiator cap after replenishing the supply of fluid, it is liable to be lost owing to the vibration set up in traversing rough roads. Edmund B. Nelson, Cadiz, O., has invented a radiator cap which presents many practical features inasmuch as its construction is such that the member cannot be lost and considerable time is saved in filling a cooler as unscrewing the cap is avoided. The device consists of a lid pivotally mounted or hinged and fitted with a spring for the purpose of throwing the lid open when the spring member is released. The latter is concealed and attached to the lid is a perforated lug extending downward into which fits a spring actuated pin. This is provided with a cam face mating with a similar member of the cylindrical casing whereby when the knurled head of the pin is turned the pin itself will move outward, releasing the lid.

Some Recent Patents of Interest to the Commercial Vehicle Operator, Manufacturer and Dealer.

FOREIGN TRUCK NOTES OF INTEREST

WHITE TRUCK IN CHINA.

The progressive ideas with which the present government of China seems to be imbued are expected to result in opening a decidedly successful market for all types of modern equipment, including, of course, the pleasure and commercial automobiles. Pleasure cars have been in more or less constant service in certain sections for some time, but it is only recently that motor trucks have been seen in China.

Among the first was a White, made by the White Company, Cleveland, O., one of the vehicles utilized by the United States army in the Philippines. When the American forces were sent to China during the recent disturbances, they were accompanied by this machine, which was fitted for all emergencies and did excellent work in connection with the troops of the allied forces.

White Truck Which Accompanied United States Troops to Northern China During Disturbances in That Country Recently.

An accompanying illustration shows the car upon its arrival in Chin Wang Tao, North China, as it was being prepared for its journey inland. As might be expected, it attracted considerable attention from the natives, and it hardly need be mentioned that the Chinese business men found opportunity to watch its progress in the difficult task before it.

SPLENDID MARKET IN JAPAN.

The business men of Japan have been investigating the commercial vehicle with the result that they are rapidly becoming convinced of its thorough practicability and efficiency. The roads in that country are not such as to indicate the most successful operation of mechanical transports, but the government is committed to a policy of remedying these conditions as rapidly as possible. Several machines of British manufacture have been utilized with very satisfactory results, and the Japanese are about prepared to purchase in increasing quantity.

Vehicles destined for use in Japan should be capable of hard wear. The roads in some of the mountainous districts are exceedingly bad, and there is a decided scarcity of experienced chauffeurs and mechanics. On account of the narrow city streets, cars ought to have short and narrow bodies, easily steered front wheels, strong brakes and durable rubber tires. The manufacturer who develops this field in the proper manner is sure to secure a permanent market.

PROPOSED SOUTH AFRICAN TARIFF.

As chronicled in these columns recently, business men and farmers in South Africa have become convinced of the utility of the motor vehicle and are prepared to purchase on a satisfactory scale. Closely following this information comes the news that the Union Parliament of South Africa (British) practically has agreed upon a policy to impose a tariff on all motor vehicles shipped to that section. It is presumed that this will include a preferential clause in favor of British made products. However, there is a division of opinion concerning the whole project and the Legislature now has a majority and minority report before it for consideration.

STREET CLEANERS IN PARIS.

As a result of the recent tests conducted by the city of Paris, France, 30 combined motor watering carts and street sweepers have been purchased from the De Dion-Bouton company. The chassis of these machines will be the regulation 18 horsepower type, so generally used on the Continent.

TAXICABS IN BRAZIL.

Germany has been decidedly successful in developing trade in South America, as is evidenced by the recent order for 35 taxicabs received by the Neue Automobil Gesellschaft from a concern operating in Rio de Janeiro, Brazil. These vehicles are of the open type, seating four passengers, and are constructed on the regular N. A. G. 12-14 horsepower, four-cylinder chassis.

FIRE APPARATUS IN IRELAND.

The police committee of the town council in Belfast, Ireland, has approved the report of a sub-committee recommending the expenditure of practically $50,000 in the purchase of modern motor fire fighting apparatus. The plan embraces the entire replacement of the present equipment of horse drawn vehicles, including the steam fire engines.

MOTOR MAIL WAGONS IN BAVARIA.

Beginning last month, a new motor mail line connecting Nuremberg and Erlangen in Bavaria was opened, covering a distance of 11 miles. The city of Nuremberg has guaranteed the success of the enterprise to the amount of practically $900, other interested communities bearing the cost of constructing and maintaining the requisite garages. The municipal authorities of Dachau are interested in a similar proposal concerning a line to Odelzhausen.

Digitized by Google

ELECTRICS IN AUSTRALIA.

The city of Melbourne, Australia, has decided to import one or more electrically driven motor vehicles for use by the municipal authorities. This is a type of machine which has been given but little trial in the commonwealth, and many business men are watching the innovation with considerable interest. The Australian market has been decidedly active for gasoline trucks during the past year, and it would appear that manufacturers of electric vehicles would do well to watch the experiment under the direction of the Melbourne officials.

MOTOR HAULAGE IN PATAGONIA.

Owing to the scarcity of grass in southern Patagonia, it is impossible to employ the bullock teams, and those who have been engaged in developing this country have been making tests of motor transports for some time. Practically the first machines imported into this country were two gasoline tractors of American manufacture. The rough roads and the light construction of the vehicles proved to be a combination which did not result satisfactorily. However, a machine of the same make and type is still in use in that country, although the consumption of fuel is admittedly very high.

The Sociedad Explotadora de Tierra del Fuego uses steam tractors on its Ultima Esperanza section with success. Another successful machine is a Fiat, which has been working there for about three years, making frequent trips to Rio Gallegos and Guer-Aike, a distance of 21 miles, and carrying three tons each way.

Two British vehicles, a steam Mann and a gasoline Marshall, are also being used in the same territory. The first operates at a rate of seven miles an hour with a seven-ton load, while the latter frequently makes trips to Guer-Aike, drawing loads up to 25 tons.

It would appear that an excellent field might be developed for specially constructed machines. Despite the absence of grass, other crops are grown easily, and the farmers of that section are anxious to obtain some satisfactory means of hauling their products to market.

AMERICAN AMBULANCE FOR BRAZIL.

An accompanying illustration presents a Pope-Hartford ambulance, made by the Pope Manufacturing Company, Hartford, Conn., for use in Rio de Janeiro, Brazil. The vehicle is much the same as those which have given excellent satisfaction at home. The inside equipment includes beds, stretchers, medicine chest, folding seats for surgeons and nurses, speaking tube from surgeon's seat to driver's seat, and two dome electric lights in the roof.

The chassis is fitted with a 50 horsepower motor. Wheelbase is 136 inches, tires 38 by 5.5 inches in front, and 39 by six inches rear, with demountable rims. The body is of wood, having a floor space of 38 by 93 inches, with inside height of 58 inches. The roof and inside walls are finished in mahogany, with doors on either side and double doors in the rear. These latter have double locks, operated from either inside or out, and each door has a plate glass window 13.5 by 22 inches. Springs are of the finest quality, giving comfortable carriage of the sick and injured.

GERMAN SERVICE IN AFRICA.

Work is progressing favorably on the proposed motor truck line between German East and West Africa, across the Continent and through the Belgian Congo. Considerable construction will be necessary, and a new road must be cut through forests and mountainous country, and bridges thrown across rivers, before the vehicles will be able to make the trip.

NO HORSE CABS IN BERLIN.

Beginning April 1, no more horse cabs will be allowed upon the streets of Berlin, Germany, in compliance with an edict issued by the police authorities of that city. It is maintained that the vehicles in question have become so utterly obsolete as to be wholly unworthy of such an up-to-date city as Berlin. To each of the 60 licensed drivers affected by the new regulation $150 has been paid by way of compensation, and it is announced that their application for permission to operate motor cabs will be considered favorably. This is a step which will be watched with interest by other Continental countries following closely the example recently set in Paris.

Pope-Hartford Ambulance Recently Shipped by Pope Manufacturing Company to Rio de Janeiro, Brazil.

AGRICULTURAL TRIALS IN FRANCE.

The recent agricultural trials in France were not as successful as those in charge had anticipated. The difficulty appears to have been in the failure to attract a sufficient amount of competition. It is announced in this connection that the Societe Nationale d'Encouragement a la Agriculture, having former President Loubet at its head, will undertake the holding of an important agricultural motor congress in 1913, and that manufacturers of farming implements in all countries, not only will be invited, but urged to compete.

A considerable competition is expected in connection with the trials at Bourges from Sept. 25 to Oct. 6, under the auspices of a committee, of which Prince Pierre D'Arenburg is chairman. All particulars are to be obtained from the office of the commission, 14 Avenue de la Gare, Bourges, Cher, or from the secretary of the agricultural committee of the Automobile Club de France, Paris.

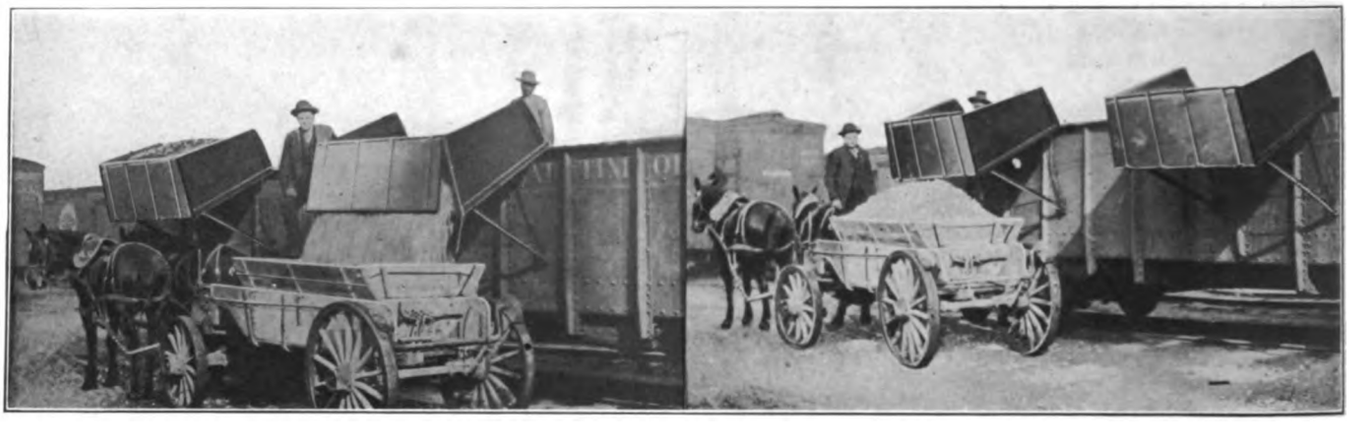
SOLVING THE QUICK LOADING PROBLEM.

Interesting Device Developed for Application with Horse Drawn Equipment, Which May Be Utilized with Satisfactory Results in Motor Vehicle Haulage.

THERE is little disposition to dispute the fact that until the appearance of the practical motor truck, few operators of horse drawn equipment gave the attention to the matter of economical and efficient haulage that its importance warrants. This applies equally to the man who is compelled to rely upon others for the solving of his transportation problem and to those who are engaged solely in the matter of haulage. Only those who have made attempt to gain information upon which to base comparison between the relative cost of mechanical and horse drawn equipment can appreciate the full force of this statement.

Many men hesitate to adopt newer methods in this branch of their business, largely because they are not well informed as to the cost of their present facilities. Draught animals have been employed in hauling materials and goods for many years, but there practically are no data available from which it is possible to learn whether or not their use is costing more today than 50 years ago, for instance.

When the motor truck salesman first approached the business man it was with the argument that he could effect economy. Careful compilation of figures for a given period, based upon the amount of work that a particular vehicle could perform in competition with horses, proved that this was true. But the business man often failed to become convinced, even with the figures before him, and the reason is to be found in the item of efficiency.



It matters little that a mechanical transport can accomplish more work than horses, if it is not to be worked to something like the limit of its efficiency. It is only under such conditions that it is able to show the maximum economy, and with certain lines of business this becomes a decided problem in itself.

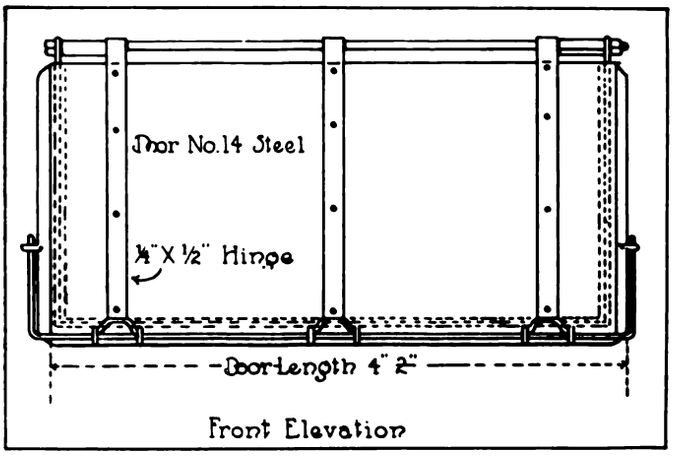
The successful competition of the motor truck has occasioned considerable more thought with respect to the transportation question, even with those who for one reason or another feel compelled to continue with horses. The careful compilations which have been made in recent years have served to inform the business man as to what his horse drawn vehicles should cost, and there is no doubt that this agitation has resulted in endeavor to secure ways and means of improving their efficiency. The owner and prospective purchaser of mechanical transports can learn much from a consideration of some of these innovations.

In accompanying illustrations is presented a quick loading chute, which was produced by the Quick Loading Car Chute Company, Birmingham, Ala., primarily for the benefit of horse owners. Ample demonstration appears to have resulted in increasing the efficiency of the horse wagon by nearly 100 per cent. There seems to be no reason why the same equipment should not work similar, if not more favorable results with motor vehicles.

As indicated, the chute is designed for attachment to cars or bins for the handling of coal, grain, etc., but there are numerous other uses to which it might be put with equal success. Line drawings herewith give a clear idea of the construction. It is made of steel and angle iron and is so designed that it may be hooked to the top of the car by means of two large hooks, which may be attached to the bottom frame of chute at three different points, according to the size of the vehicle to be loaded.

Depending upon the relative heights of the car sides and the wagons, the chutes are adjusted with a chain, by hooking up which the front of the chute is raised, and by letting down it is given greater inclination. It is necessary to fit the hooks securely to the top edge of the car, and not to let the ends rest on the contents. If the car be full, a space should be cleared for this purpose. The curved part of each hook must be in close contact with the edge of the car. If these precautions be taken, the chute is said to be able to sustain double its rated capacity.

Quick Loading Chute in Operation: At Left, Team Beginning to Take on Load; at Right, Wagon Fully Loaded.



The method of use is obvious from the photographs. Two or more of the chutes are attached to the side of the car or cars, and a man is detailed to fill each. The wagon is placed in position underneath and trap is sprung. As many chutes are dumped as are needed to fill the vehicle, and while this load is being delivered, the men have opportunity to refill the chutes.

By this method, it is possible to discharge the contents of a chute into the wagon in 10 seconds. Assuming that it is necessary to utilize the contents of two chutes, the vehicle is detained less than a minute and may be on its way to deliver the load.

Not only is time saved on the part of the wagon or truck, but there is no waste time on the part of the men who do the shovelling. Under the old arrangement, the men are forced to remain idle during the periods when no wagon is awaiting a load at the car. With the new plan, the men are always busy, and the teams are moving all the time. There is no waiting for wagons and no wagons waiting for loads.

Digitized by Google

Still another item enters into the consideration where these devices are used in connection with unloading railroad cars. As is well known, railroad companies are continually

Drawing Indicating Construction of Quick Loading Chute.

demanding the use of their rolling stock, and in order to insure that they shall have such use so far as possible, demurrage charges are collected after a stipulated time, if a consignee is unable to release the car. Any method which will make for quicker work in unloading the contents of a car lessens the possibility of demurrage.

That this is by no means an unimportant consideration, is the better understood when it is stated that many contractors throughout the country are called upon frequently to move from 10,000 to 15,000 tons of one class of bulk freight at a time. More than 250 concerns in 35 states are using the chutes described, as well as many in Canada and the insular possessions of the United States.

Chutes are made in three standard sizes as follows: Capable of holding .75 cubic yard, shipping weight, 216 pounds; one yard, 285 pounds, and 1.5 yards, 324 pounds. The drawings present the exact proportions.

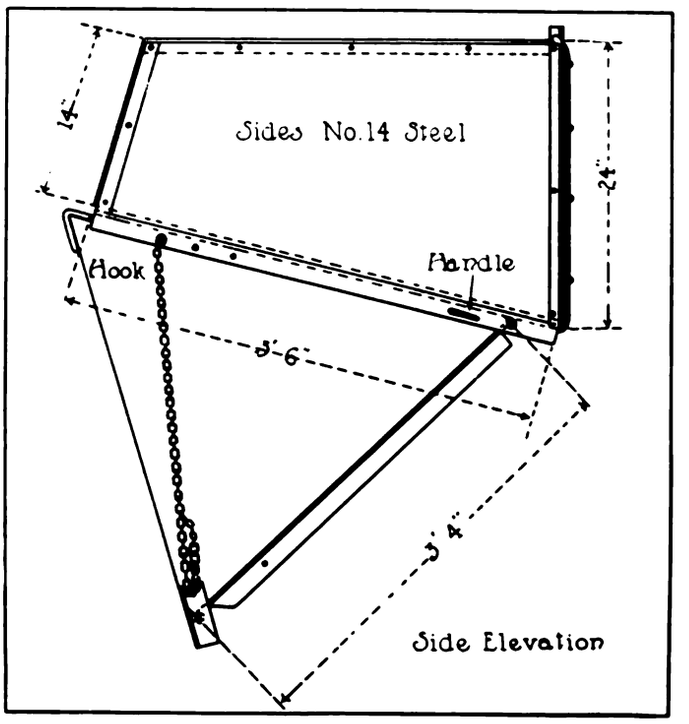
BUSINESS MEN AND TRUCKS.

"The pleasure automobile has been in the foreground long enough," declares T. R. Lippard, vice president and manager of the Lippard-Stewart Motor Car Company of Buffalo, N. Y. "In the automobile business we have seen an instance of the reversal of the old motto, 'Business before pleasure.'

"The pleasure car got the start because it ministered to the pleasure-loving instincts of the people. The motor truck was meant for business purposes, and business men are conservative.

"The merchant who bought a pleasure car and careered joyously through the country is slow to contemplate the abandonment of horses and wagons for the transportation of his goods. The change would involve expense. He would have to dispose of the plant he has, at a sacrifice perhaps, which certainly would be more costly at the outset.

"But he is gradually becoming converted. Though the initial cost of a motor truck may be greater, it is an untiring servant. Unlike the horse, it can work all day long. It is never so galled and footsore that some humane policeman has to order it back to the stable, and it does not obstruct the street like the horse and wagon.



"The public is interested in the motor delivery car, because it will reduce the traffic congestion in cities about 20 per cent. That ought to, but may not, appeal forcibly to the merchant. The saving in money through the motor vehicle must appeal to him mightily, when he has been made to see it."

G. M. C. TRUCK AIDS FACTORY.

The superiority of the commercial vehicle over all other forms of transportation in the case of emergency was demonstrated recently at the plant of the Spink Manufacturing Company in Philadelphia. The power plant was put out of commission by the breaking of a large cylinder and a new one could be procured only at Newark, N. J., a distance of 95 miles. Not wishing to tie up the factory while waiting for the machinery to be shipped by the usual methods, a G. M. C. truck, made by the General Motors Company, Detroit, was dispatched with a crew to Newark. The start was made at 3 in the morning, and in spite of a severe rain and wind storm the car reached Newark at 2 in the afternoon, loaded on the cylinder and started the return trip shortly after 5. By this time the rain had changed to hail and the 3.5-ton machine encountered many difficulties on the return trip. In some places large limbs from trees obstructed the roads, compelling the crew to stop and remove them. The automobile arrived in Philadelphia at 1 in the morning, having covered a distance of 170 miles, and during the entire trip the car ran perfectly.

FUEL ECONOMY IN OPERATING.

That there is a considerable difference in the amount of gasoline used by a vehicle when operated by a competent and an inexperienced driver was proven recently by a novel test conducted by William H. Stewart, Jr., of the Mais Motor Truck Company, Indianapolis, Ind. In the first test the course was covered by a driver using the same judgment as the average experienced man. Then a man was placed behind the wheel and made to drive the same distance after being shown how to operate the car as would be the case in teaching a new owner. The results were very surprising. The experiments showed that 34 per cent. more fuel was consumed by the inexperienced operator than was used by the regular driver. Of course, it will be admitted that

Illustrating Provision for Attaching Chute in Position.

the inexperienced man will soon be able to overcome this difficulty and no suggestion is made that it is necessary to employ experienced chauffeurs for motor truck work.

ELECTRIC CAMPAIGNERS BANQUET IN BOSTON.

Manufacturers Discuss Some of the Reasons Why This Type of Vehicle Has Failed of Adoption in New England and Suggest Methods for Increasing Its Use.

CELEBRATING the first anniversary of the beginning of an electric vehicle development campaign in Boston, the Boston Electric Vehicle Club held a banquet in the Hotel Thorndike in that city early in the month, at which some 150 were present, including many prominent business men in Boston and vicinity, and electric vehicle manufacturers and dealers. The president of the club, Day Baker, local representative of the General Vehicle Company, Long Island City, N. Y., presided, and E. S. Mansfield of the Boston Edison Electric Illuminating Company was toastmaster.

P. D. Wagoner, president of the General Vehicle Company, spoke in part as follows:

"I think it must be conceded that when hundreds of the largest firms in the country officially adopt the electric for their city delivery service, they must consider it perfected, at least to the extent of being superior to horses and more economical than non-electric trucks for this work. When I tell you that 100 firms already use 1009 electric trucks of one make—that two express companies have purchased no less than 356, two brewers 172, three packers 110, three delivery contractors 93, and three central stations no less than 158, and when you consider further that in the case of the express companies, the brewers and the central stations, many of the electrics now operated by them have been in service from six to 11 years, you must admit that such extensive buying not only voices confidence in the electric, but demonstrates as well that the electric truck gives a larger return on the investment than other types of commercial vehicles.

"This is certainly true of city work, and the bulk of heavy trucking and deliveries is in the city. The fact that in changing from horses to electric trucks, you can utilize your regular horse drivers does much to simplify the operating and economic problem of the man who is adopting motor vehicles. Many of the horse drivers possess a valuable knowledge of the firm's routes and methods of delivery.

"I am not exaggerating when I say that with about 48 hours' instruction by a competent demonstrator, the average teamster can be taught to operate successfully a five-ton electric truck. That is, he will be able to take it around corners without taking the lamp post with him, back into alleys or doorways, go down grades at a safe pace, etc. Furthermore, most drivers are not only willing, but anxious to drive the electrics.

"We do not use electric light because it is cheaper than a tallow dip—it is better. Our competitor uses it—we must keep abreast of the times. Progress is essential and progress demands it. We do not use elevators because they are cheaper than walking. Modern conditions require modern equipment.

"Automobiles for pleasure and commercial purposes are going to be used regardless of economy of operation. Automobiles are in line with the restlessness, the progress and the spirit of the age. The people are bound to have them.

"The motor truck is a money saving proposition, yet the world is going to have it because it is up-to-date, a part of modern business. Electricity provides the solution of most of the transportation problems of our cities and towns. The people like electricity. It is a good, clean product. I bow to that great silent force."

Another speaker was William Kennedy, a consulting engineer retained by the Baker Motor Vehicle Company, Cleveland, O., who said in part:

"It may well be conceded that after 10 years' successful employment in economic service the electric vehicle has ceased to be an experiment and is as well developed as most of the industrial apparatus which we are at present using in commercial life, as absolute necessities to present day conditions. We may be well convinced of this when we consider that the electric vehicle, particularly in its industrial application, is nothing more than a modification of the electric street car, having the same engineering foundation for its design and production.

"With the practical example of nearly 5000 commercial vehicles and over 15,000 pleasure vehicles in successful employment there is today considerable wonder that they are not more universally employed, and the conditions tending to obstruct their almost universal application are well worth studying with the object of eradicating whatever impediment there may be, and giving such impetus to the propagation of their use as to establish in the minds of prospective machine users unquestionable confidence and an inclination to substitute them for the present or existing horse methods with the remarkable reduction in operating expense which would accompany the change.

"A peculiar feature of the increasing business, however, is the fact, generally admitted, that for the past two years nearly 70 per cent. of the commercial vehicles put into service were purchased by firms already using electric trucks, so that the gain in new business secured by manufacturers represents only about 30 per cent. of their total output.

"This indicates two things, which are somewhat difficult to reconcile. One is that this type of machine is so economically successful as to warrant continual increase in the equipment already in use, and the other contrasting feature is that notwithstanding this convincing example to the industrial and mercantile community it does not create a proportionate desire on their part to avail themselves of this economic apparatus.

"It may be interesting locally to know the fact that while there are between 4000 and 5000 commercial machines used elsewhere, Massachusetts is at the present time employing only 170, of which 87 are in Boston proper and 111 in Boston and its immediate vicinity; and the total for New England would probably not exceed 200 electrics, while there appear to be in the same district 1800 gasoline commercial cars. The apathy of the New England district is the more conspicuous in view of the fact that no corresponding territory has had expended upon it anything like the same amount of intelligent and persistent effort to educate the prospective users in the benefits to accrue from the use of these machines, as well as to stimulate effort on the part of those engaged in advancing the propaganda.

"If this situation is to be improved we must broaden our efforts and invite the co-operation of, not only those immediately interested in the sale and use of machines, but every other influence at work in promoting the employment of electric utilities. The more we encourage the public habit of using electric vehicles or electrical service in any form the more we stimulate the general interest with corresponding reflex individual benefit to its various other divisions.

"The present impediment to progress in this direction is a lack of familarity with the real simplicity of the problem. There is an inclination to surround electric vehicle employment with a good deal of unwarranted mystery and to

Digitized by Google

lay stress on minor non-essential items which may happen to be questionable at the moment, instead of looking broadly at the conspicuous advantage which machine use possesses.

"Among the greatest difficulties which we encounter in this work is an almost complete absence of knowledge on the part of the users of horse service as to the cost of their transportation except in the few cases where the service is hired or transportation is the principal part of the business, but until the advocates of motor vehicle employment attempted to make the substitution of machines for horses on an economic basis, it is a fact that reliable horse transportation costs were unknown to the average merchant. The necessity of this information is now being recognized by them and they are gradually informing themselves, although the subject is handled in a very crude way by most of them.

"Again, even where we find the prospective user inclined to consider machines favorably we discover a strong disinclination to change the method which has been convenient with the use of horses, to any new scheme of operation which may be necessary to utilize the capacity of the machine. There are also existing obstacles at loading and unloading points, which are the great causes of waste in any system, present or future, which must be eradicated before long as an economic necessity, even independent of the use of motor vehicles.

"We have several splendid advantages in presenting economic facts in relation to the cost of operating electric machines on account of the fairly accurate records which have been kept, particularly in large installations over long period, covering upkeep of the wearing mechanical parts, batteries and tires, and these three essentials are after all the only items that are subject to the slightest doubt in presenting the cost of operation.

"For the purpose of putting some fact forward to substantiate the generally accepted knowledge among us that remarkable economy may be effected by the substitution of machines for horses, the attached table is presented, showing the results of some very complete and exhaustive investigations made with a long period of time devoted to each case and adequate facilities afforded to arrive at an exact knowledge of existing horse cost and to demonstrate beyond question to the prospective purchaser the performance and the cost of operation of the proposed machine equipment. These cases are selected at random from a large collection and represent the transportation departments of prominent and well known commercial institutions in several of the principal cities. The names are omitted purposely as otherwise this information could not be presented.

"Two classes of service are covered in this tabulation. One representing haulage of heavy loads requiring vehicles of two and five tons capacity and the other group representing medium service where the vehicles are largely composed of ton and half-ton machines as well as some larger sizes in minor quantity.

The figures relating to horse equipment are certified to as correct by the respective owners of the installations and the machine equipment has been determined in every case after a complete consideration of the characteristics of the work and extended demonstration with the actual use of machines to prove that the expected accomplishment was practicable. These demonstrated results have been agreed to as convincing and satisfactory by the interested executives in every case, and therefore the entire matter is as nearly fact as it is humanly possible to develop it."

COMPARISON BETWEEN HORSE DRAWN AND ELECTRIC EQUIPMENT.

No. of Horses	No. of Machines	Investment—Horse	Investment—Machine	Expense—Horse	Expense—Machine	Annual Saving	Per Cent. in Earnings on the Investment	Per Cent. Saved Over Horse Expense

MOTOR TRUCK CLUB'S ANNUAL MEETING.

The Motor Truck Club in New York City is doing excellent work in connection with the correction of trade abuses. Many little practises which have stood in the way of complete harmony between buyers and sellers have been brought into disrepute and practically eliminated. This is best exemplified by the fact that one member, a truck salesman, whose methods were held to be detrimental to the development of the commercial vehicle industry, has been expelled, and the principle has been established that the club stands for fair representation in the matter of truck salesmanship.

At the recent annual meeting, held in the rooms of the Automobile Club of America, the following officers were elected: President, D. C. Fenner, manager of the Metropolitan branch of the International Motors Company; vice president, Emerson Brooks, vice president of the Remington Standard Motor Company; secretary and treasurer, Charles E. Stone, Hexter Motor Company; managerial board, F. B. Porter, Chase Motor Company; E. Lascaris, De Dion-Bouton; E. O. Hoopengarner, Swinehart Tire Company; A. N. Bingham, Hewitt; E. W. Curtis, Jr., General Vehicle Company; A. J. Slade, consulting engineer; John Hanson Kennard, Couple-Gear.

MAY HAVE AUTOMOBILE LINE.

While until recently very little effort was made to develop the sale of commercial vehicles in the Rocky Mountain district, the people of that section appear to be quick to realize the benefits to be obtained through the use of mechanical transports. The latest information indicates that a practical demonstration of the motor 'bus for cross country transportation is to be granted by H. M. Lamson of Mesa, Ariz., who has organized an automobile line to be operated between that city and Phoenix.

Cars are to be run on a fixed schedule, arriving and departing every two hours, from 7 in the morning until 11 at night. The fare will be five cents a mile, single mileage, although coupon tickets will be issued good for 500 miles at three cents a mile. Stops will be made at any point on the line, the same as with trolley cars, and it is expected that the farmers throughout the district will furnish a decidedly important share in the success of the venture.

FIRE DEPARTMENT NOTES

It was announced recently by the International Motor Company, New York City, maker of Saurer, Mack and Hewitt commercial vehicles, that Saurer fire apparatus would be manufactured at its Plainfield, N. J., plant. In the accompanying illustration is presented one of the types to be made, this machine being in service at St. Gallen, Switzerland, the original home of the Saurer automobile.

The vehicle is a complete piece of apparatus and is propelled by a 60 horsepower motor. In a test at Bound Brook, N. J., a similar machine delivered a stream of water of greater volume through six lengths of 2.5-inch hose than steamers of that section could produce. Another test consisted of coupling four separate hose to the connections of the pumping device and it was shown that the streams were of good size. When connected to a city hydrant, where the water pressure was about 65 pounds, the pump drew this down to less than 30 and raised the pressure at discharge to 136 pounds.

The pump is of the centrifugal type and is said to be capable of delivering 550 gallons of water a minute at a pressure of 150 pounds. Two suction connections are provided for the purpose of taking water either from a hydrant or a stream. The pump is located at the rear of the chassis and is controlled by a hand lever.

Saurer Combination Hose, Hook and Ladder and Pumping Engine in Service at St. Gallen, Switzerland, Duplicates of Which Are to Be Manufactured in This Country by the International Motor Company, New York City.

Fire Commissioner Joseph Johnson of New York City, through whose efforts the horse drawn equipment is being replaced as rapidly as convenient, and who is perfecting a thoroughly efficient motor fire department, has adopted plans whereby a competent staff of automobile mechanics and drivers will be in constant readiness to perform the duties necessary to keep the equipment in active operation.

The commissioner's plans are entirely his own and were adopted after consultations with manufacturers and technical experts. The change involves the disappearance of the old drivers and engineers and to some extent the entire personnel of the department. To bring these conditions about and not to impair the efficiency of the department, a school of automobile engineering was established.

To motorize a horse fire department requires time, labor and experience, and with the material to work on, unfamiliar with motor propelled vehicles, the task has been unusually difficult. It is interesting to note, however, that of the 127 men who have been members of the school no less than 120, or 95 per cent., have graduated. Each of the 120 is not only capable of operating an automobile, but can assemble a motor and perform such duties as are required of an ordinary automobile mechanic.

The school was started last September and no special qualifications on the part of the applicants were required. After being elected, the men are formed into classes of 25, and for the first 10 days the members are instructed in the simple rudiments of motor construction. If during this time, any member shows himself to be deficient, or, in other words, fails to grasp the details, he is sent back to his company.

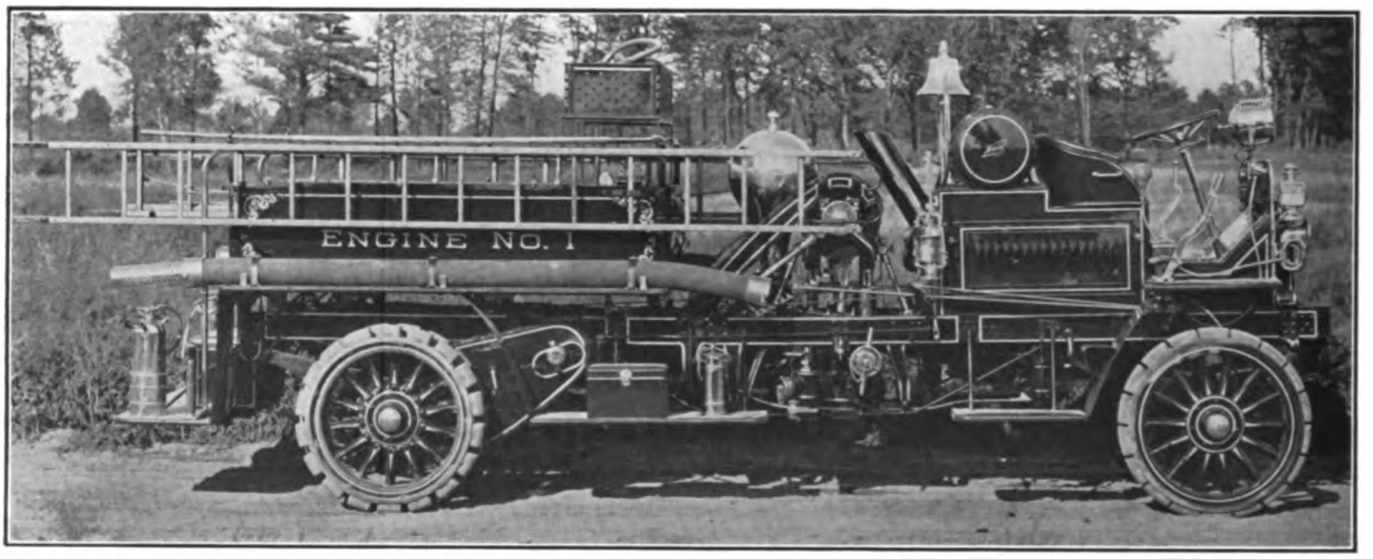
The term consists of 30 working days of six hours each. During this time each student is required to become familiar with minor difficulties which might be encountered upon the road. After being admitted to the class, each member is presented with a list of 30 questions which are explained in detail by the instructor. These questions cover the final examination, and must be answered in a satisfactory manner to secure a certificate of graduation. In addition there are 300 questions covering the working of the motor, these being sub-divided and relating to operation and troubles of the components of the machine.

Applicants are received between the ages of 22 and 40, although exceptions have been made in some instances. The men report to their respective stations after 6 in the evening for regular duty. When the member is presented his certificate he is warned that his work will be watched constantly, and should anything occur to warrant it the certificate will be cancelled. This is done to maintain the proper efficiency of the department.

A feature of the school is the regulation of speed on the city streets. The limit is 15 miles an hour, but many of the students desire to drive at a rate of 25 miles, and in order to guard against this Commissioner Johnson had the cars fitted with governors which confine the speed to the lower figure.

During the next year 42 companies will be organized, and to complete the equipment for these, 200 more men must be educated. In speaking of the methods utilized the instructor, Capt. J. J. Henry, says the men are educated on engine construction, transmission, clutch and differential, cooling methods and lubrication. Ten days are allowed for preliminary work and at the end of that time, if proficient, the student is instructed in the control brakes and clutch levers and the use of fuel and lubricants.

Passing these tests the members are assigned to the duty of disassembling a motor and transmission. Ignition and carburetion is then taken up and lectures given upon these subjects. At the end of 20 days the class is given instruction in road work and exhaustive tests must be



Digitized by Google

complied with, such as operating in crowded traffic and at different speeds.

The motor equipment at present consists of 10 hose wagons, one front-drive propelled steam engine, one Couple-Gear water tower and four hook and ladder wagons of similar design. Commissioner Johnson advertised recently for bids to supply the department with 26 combination chemical and hose wagons of the flying squadron type, three wagons of the high pressure type and three machines without chemical attachment. The total cost will be in the neighborhood of $700,000.

As a result of visits to the commercial car shows at New York City and Boston, Portsmouth, N. H., is to have a Pope-Hartford chemical wagon, made by the Pope Manufacturing Company, Hartford, Conn. The mayor of Portsmouth and chief engineer placed the order at the Boston show and delivery will be made June 15. The machine will cost $5000 and will be fully equipped.

Many towns and small cities make it a practise to establish a central station in which is installed apparatus capable of affording protection to the entire community. While the equipment is limited it must be of high efficiency and capable of covering considerable ground rapidly. Many of these municipalities cannot afford to purchase several pieces of automobile apparatus and to meet these requirements the Knox Automobile Company, Springfield, Mass., is producing a vehicle which in itself is a complete department, combining as it does the hose cart, hook and ladder truck, chemical and pumping engines.

New Knox Combination Apparatus, Made by the Knox Automobile Company, Springfield, Mass., Which Is a Fire Department in Itself, Exhibited at the Boston Show Recently.

In the accompanying illustration is presented the machine which was shown at the Boston show recently where it attracted considerable favorable attention among visiting officials of towns and cities contemplating the purchase of the motor propelled apparatus. The car is propelled by a powerful six-cylinder motor which operates a pump capable of pumping several hundred gallons of water a minute. The machine is equipped with a chemical tank, the hose for which is carried in a cage, making for accessibility. Hand chemical tanks are fitted, also a number of ladders; in fact, all modern fire fighting devices are included.

The body provides ample seating capacity and throughout the material is the best and the workmanship of the highest quality. Solid tires are fitted, single in front, and dual in rear, and drive is by chain, fully enclosed. The construction of the chassis is in keeping with the high grade established by the Knox Automobile Company and the design should find favor with municipalities contemplating the installation of automobile fire apparatus.

Ipswich, Mass., depends upon a volunteer fire department for protection, and the members of this company are to be commended for their progressiveness. For several years the company has desired an automobile, but the town fathers could not see their way clear to appropriate the money. The company was undaunted, however, and began a series of entertainments for the purpose of raising money enough to purchase a piece of motor propelled apparatus. The townspeople warmly supported the efforts of the firemen and after raising a little more than half of the sum required, enlisted the aid of the town officials who contributed the difference. An order was placed with L. B. Butler of the Butler Motor Truck Company of Boston, now with the General Motors Truck Company, Detroit. The machine, which was delivered recently, is a combination hose and chemical wagon, having a 25-gallon tank and 500 feet of hose. In addition it carries ladders and the usual equipment. It is lighted by electricity. A feature of the truck is the fitting of the original Bonney-Cot bell, taken from a hand cart in Boston, which was cast in 1852, taken to Ipswich and kept as a relic by one of the residents who presented it to the fire company.

The fire department officials of Boston were given an opportunity to note the practicability of the motor propelled vehicle recently when a ladder truck was driven from Longwood and Brookline avenues, Roxbury, to the top of Parker Hill in less than three minutes. The machine was a product of the American-La France Fire Engine Company of Elmira, N. Y., and was handled by a representative of that concern who was unfamiliar with the route. The truck will be in service at Forest Hills for one month during which time it will answer alarms and its work will be watched by the department officials. If it proves satisfactory, steps will be taken to secure its purchase. The machine carries a complete equipment of ladders, two 40-gallon chemical tanks and 200 feet of hose, in addition to the usual fire fighting apparatus. It is propelled by a four-cylinder, four-cycle water-cooled motor and is equipped with a hydraulic transmission affording any number of speeds.

SOLVING CONTRACTOR'S DUMPING PROBLEMS.

Lynch Special Bodies Provide Means for Handling All Classes of Material in Simple and Effective Manner with Substantial Saving in Time and Labor.

BECAUSE of the superiority of the mechanical transport over horse drawn equipment in the matter of quick haulage, as well as in economy of operation, it makes a decided appeal to building and excavating contractors, as time is money in every sense of the word in these lines. But, as with numerous other industries, some means must be devised for rapid handling of materials if the motor truck is to give its maximum of efficiency.

In order to consider this matter more fully, let it be assumed that contract calls for creating a substantial railroad bed across a large swamp. Under these circumstances, it usually will be necessary to secure the material at some little distance from the swamp. To be sure, the railroad might be utilized in conveying loaded cars from the excavating point to the place of dumping, but those who are most familiar with operations of this nature, will agree that the contractor is forced to secure his material wherever possible, and teams are much more frequently called upon to do the hauling.

The motor truck offers an ideal solution of the difficulty, but there are other considerations than the mere hauling of the material. For instance, it manifestly would be impossible to run any loaded wagon, no matter what the type, over the swamp itself. Material might be drawn to the extreme limit of the graded portion of the right of way and dumped, but this would mean a large force of men at this end of the work, as well as at the scene of excavation.

Realizing the importance of time in this respect, Charles Lynch of the Lynch, Brandenberger Company, Chicago, Ill., a firm engaged in excavating and general teaming with sand, gravel, etc., recently devised a portable dumping body or box, which this concern has utilized with splendid success. This body is now made in a wide variety of types for all classes of work, and marketed by the Lynch Manufacturing Company, South Chicago, Ill.

Accompanying illustrations present the Lynch body in three different designs, although the photographs are of models instead of full sized truck bodies. The standard box is made to fit any five-ton truck chassis, being 4.5 feet wide, 12 feet long and any height desired. The chassis itself is fitted with a standard platform body, supplemented by a frame of eight-inch channel iron, which holds the dumping body securely in place. Fig. 3 illustrates this construction somewhat more clearly. Returning to the matter of filling in the swamp above mentioned: By using one derrick at the excavation point and another at the swamp, the equipment is completed with a standard five-ton truck and several of the Lynch bodies. The latter are lowered into the excavating hole, where they are filled either by hand or steam shovel, then lifted by derrick onto the truck chassis. Arriving at the dumping place, the other derrick is called upon to hoist the loaded box from the chassis, swing it over the swamp and dump it wherever desired. The truck is delayed at either end of the route, only long enough for the derrick to lift the empty box off the chassis and replace it with a filled box, or to take the loaded box, dump and return it to the chassis, a matter of less than five minutes.

The three types of bodies illustrated at Figs. 1 and 2 permit at least three different methods of dumping. For the swamp job, possibly that at C would prove most effective. This dumps through the bottom. The two halves are

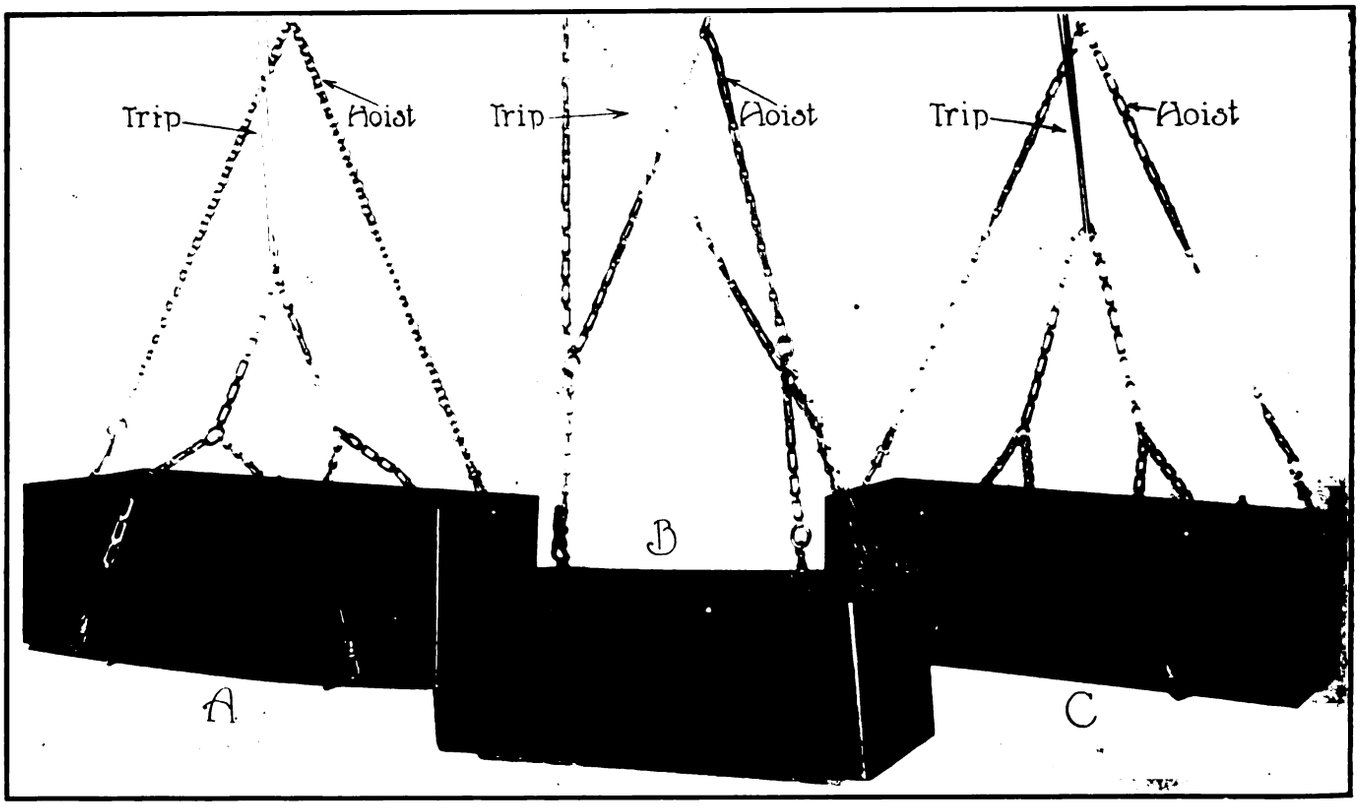

Fig. 1—Three Types of Lynch Bodies as They Would Appear Lifted Clear of Their Chassis, Preparatory to Dumping.

Digitized by Google

pivotally mounted at either end, so as to swing outward when the trip is sprung. It will be noted that the hoisting chains extend from the top of either end, and as the derrick picks up the loaded box, the weight of the material within acts to hold the two sides firmly together.

When it is desired to dump the entire contents at one time, the chains operating the trip are fastened at suitable points at the bottom of each side. As the loaded box is swung into position, a pull upward on these chains, which are brought together over the top for this purpose, causes the sides to spring outward and every bit of material within is dumped instantly.

This same type of box may be utilized for hauling brick, in which case it is not only possible to dump the entire load at a given point, but one-half of the load may be dumped in one place and the remainder in another. In this instance, the trip chains on the side in which it is desired to retain the load are unfastened from the clips at the bottom of that side and hooked in similar slips at the top. Pulling the trip then pulls the opposite side upward, to pull the rear end of the box upward as the load travels toward the opening in front.

It readily will be seen that any of these bodies could be utilized with success in excavating and dumping work, while each has a special appeal in other lines of activity. With each, the entire operation of the dumping feature is in the control of the engineer in charge of the derrick, and he has full control of the working parts at all times.

Boxes A and B also are adaptable for dumping by the motive power of the truck. In order to make such use of them, however, it is necessary to utilize a special construction, in which four jack screws play a prominent part. These jacks are placed, one each at the four corners of the frame, and are fastened to the chassis. Suitable clutches are installed to connect the jacks with the truck engine.

With box B, for instance, the operator throws in the clutches for the two front jacks and the front of the body is forced upward until the load travels out the rear, the end gate, if such it may be termed, having been raised meantime. With box A, the load may be dumped from either

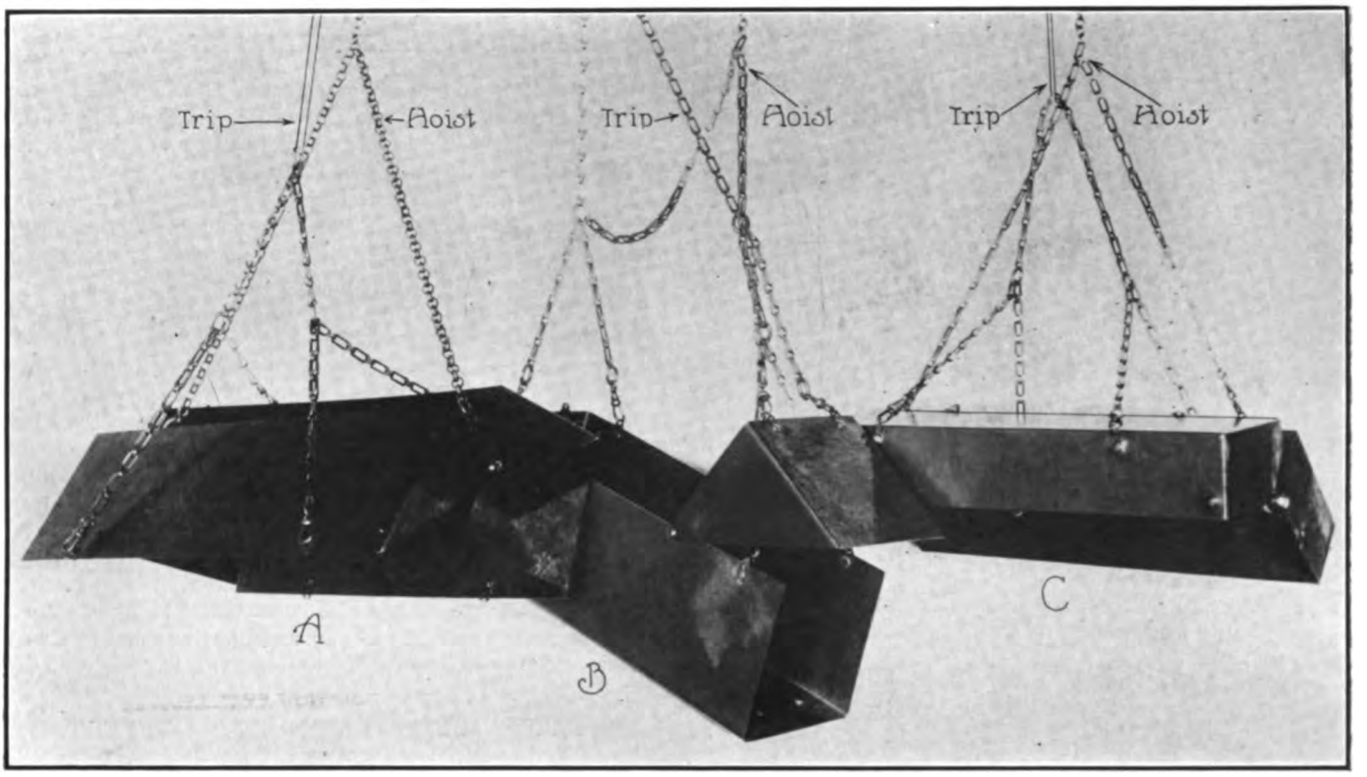

Fig. 2—The Three Types of Lynch Bodies in Dumping Position: A, Load Emptied from the Side; B, End Dumper; C, Load Released Through Bottom.

while the bricks it is desired to retain are left in the box to be dumped later by a reversal in the manner of hooking the chains.

The box at A also might be used on the swamp job, but this is designed to be dumped at the side instead of at the bottom, and it may be dumped at either side. The construction is very similar to that shown at C, with the exception that the bottom and ends are solidly retained in position while the sides swing outward, according to which side it is desired to operate in dumping.

The third box is an end dumper. One end is pivotally mounted at a certain distance on the sides, and the hoisting chains are fastened at the top at four points equi-distant from the centre. The trip is attached to the top of the end at which it is desired to dump the load, while the other is connected with the hoisting chains at the rear. When swung into position for dumping, the trip is operated in the same manner as the others, but the hoisting chain tends side in a similar manner, by utilizing the clutches for the jacks on the opposite side.

Inasmuch as all bodies are made in the same standard size, they are absolutely interchangeable. Thus it is possible to utilize the type best adapted for hauling brick today, and change to stone or asphalt tomorrow, and dirt the next day. In fact, there appears to be no limit to the possibilities afforded by the possession of a set of these boxes, although, as it is has been pointed out, it is not absolutely necessary to have different bodies in order to handle varying loads with success.

While numerous types of dumping bodies have been designed for the hauling of coal by mechanical transport, it is pointed out that the Lynch body has a special advantage in that the truck might be employed profitably in other work when not needed for the delivery of the main product. In addition, the interchangeability of the bodies is expected to have an appeal for those who desire to solve the prob-

Digitized by Google

lem of loading the truck without delay at the receiving end of the line.

Although it was such work as that of excavating and dumping, which originally developed the device, it has found ready acceptance in numerous other fields. It is unnecessary to cite a list of its many possibilities, but it will prove of interest to note how effectively it might be used in building construction, particularly with the so-called sky scrapers of the larger cities. A material saving in time and labor might be brought about by hoisting a loaded body of this type to any floor of the partially completed structure, and there dumping its load of brick, etc., without extra handling.

The Lynch Manufacturing Company has studied this system from every angle and is prepared to go over the situation with any truck owner or manufacturer who feels as it does, that the Lynch portable dumping body offers a satisfactory solution to many of the problems of motor transportation. The scheme is by no means confined to trucks of five tons capacity, and it would be possible to secure bodies equally adaptable to smaller vehicles.

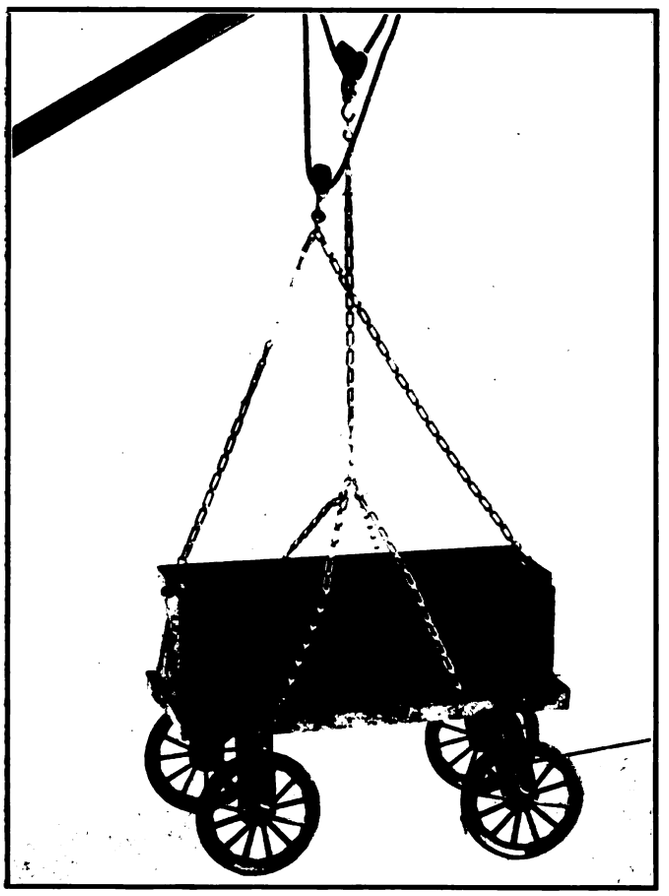

Fig. 3—Lynch Portable Dumping Body in Place on Truck Chassis, Ready to Be Lifted by Derrick.

OPERATING COSTS OF ENGLISH TRUCKS.

During the recent visit of the American automobile engineers to Europe the party discussed commercial vehicles with a prominent British truck expert, who has made a study of trucking costs as they exist in England. The authority had gathered statistics from a number of installations, and after comparing them arrived at a very fair estimate of the average cost of service in that country and gave the figures to one of the members of the party.

In comparing these costs with those in this country allowance should be made for the differences in environment, notably that of wages, as those paid to English drivers are about one-half of what they are in this country. The figures presented in the accompanying table will prove of interest:

	——Vans——		——Lorries——		
	1120	2240	2	3	5
Size of Vehicle—	lbs.	lbs.	tons.	tons.	tons.
First cost	$1536	$1752	$1936	$2856	$3336
Weekly mileage	400	400	390	350	300
	—— Operating costs a mile ——				
	Cents	Cents	Cents	Cents	Cents

CARE OF TIRES MEANS MILEAGE.

Overloading and overspeeding are conceded to be the greatest evils of the commercial vehicle as not only is the mechanism of the machine subject to stresses, but the life of the tires is shortened. D. C. Swander, manager of the New York branch of the Firestone Tire & Rubber Company, Akron, O., says there are a few simple rules which the owner of every truck will do well to instill in the minds of his drivers.

"Rubber has just so much life and no more, and if overworked cannot recuperate," explains Mr. Swander. "When the machine is overloaded or overspeeded the rubber suffers. Another thing that shortens the life of a tire is brakes that are out of true. If one be tighter than the other, one tire is subject to all the strain. Wheels should be trued up, and oil or grease should not be allowed to accumulate on the rubber. Drivers should be careful to start and stop gradually, not suddenly, and always in a straight line. By turning the front wheels before starting an unnecessary strain is placed upon the tires and their fastenings. Car tracks are also detrimental to tires. They grind away their edges. If these suggestions are followed the tire expense will be reduced considerably."

WHITE 'BUSES GIVEN SEVERE TEST.

The efficiency of motor propelled passenger omnibuses was demonstrated in Chicago during a severe blizzard in that city recently. The 55-mile gale accompanied by a heavy fall of snow tied up the street car and elevated lines and even the Illinois Central suburban service was inoperative. In spite of the conditions the fleet of 12 White 'buses, manufactured by the White Company, Cleveland, O., were constantly in service between the Northwestern depot, Marshall Field's and Mandel's. The machines ran on scheduled time during the entire storm.

PROPOSE THREE-DAY RUN.

A three-day truck run is being agitated by the dealers in Boston. It is proposed to make the event more of a demonstration of the practicability of the mechanical transport by having the machines go by easy stages from Boston to Providence and thence to Worcester and back to the starting point. A stay in each city is contemplated for the purpose of affording the business men an opportunity to inspect the vehicles.

CORRESPONDENCE ON PERTINENT SUBJECTS.

Mr. Thomas Takes Occasion to Explain His Position More Fully with Respect to Anti-Friction Bearings for Worm Gear Mounting.

CONCERNING the subject of anti-friction bearings for worm gear mounting, a discussion of which has been going on in these columns for some issues, H. Kerr Thomas of the Pierce-Arrow Motor Car Company, Buffalo, N. Y., took occasion to criticise some of the statements made by Victor W. Page of the New Departure Manufacturing Company, Bristol, Conn. In the March number Mr. Page answered Mr. Thomas at some length. In the following communication Mr. Thomas explains his position more fully:

Editor, MOTOR TRUCK,

Sir:

I have been interested in reading Victor W. Page's last letter given in your March issue, and would like to point out that having no experience on the matter, I have never questioned the suitability of New Departure bearings for use in worm gearing. My object in entering the discussion at all was to caution Mr. Page and others of your readers against the light loads explicitly specified as existing in worm gears in Mr. Page's first article. Engineering generalizations are invariably dangerous. Calculations applicable to one automobile would not necessarily be used for another.

The reason why the particular truck in which I am interested has such high loads on its bearings is owing to the fact that the entire load is practically confined to the rear axle for sufficiently good reasons. It would have been easy to distribute it had I thought this advisable.

Mr. Page, however, raises in the course of his last letter, such numbers of points that the entire design of an automobile is involved, such as required horsepower, worm efficiency for different angles, worm tooth pressures, vehicle speeds, transmission efficiency, traction efforts, motor torque, and other matters. I will only refer to two of these.

Mr. Page, in the example he gives, states that the torque at the centre of the worm shaft is 2961 inch-pounds. As I understand "torque," there can be no such thing as torque at a centre. If the torque is measured at the centre, the "inch" factor has been reduced to limit 0, hence the "pounds" factor must be raised to the limit of infinity, and I do not think Mr. Page means this.

Next, Mr. Page refers to the worm efficiency of 88 per cent. and questions Mr. Younger's claim for 95 per cent. The loss in driving through worm gears is not greater but very much less than five per cent., as a manufacturer of worm gears of the highest repute in this country can demonstrate to Mr. Page if he wishes.

I will not, however, labor this point as I have dealt with it fully in the pages of one of your contemporaries, and while I regret I must still differ with Mr. Page in many of his deductions, I must thank him for his appreciation of the friendly spirit of my criticisms. They were never offered in any other.

Yours truly,

H. KERR THOMAS, A. M. I. Mech. E., M. S. A. E.

Buffalo, N. Y., March 19.

MUNICIPALITIES IMPROVING TRAFFIC CONDITIONS.

THERE is little question that traffic conditions have a very material bearing on the successful introduction and use of the commercial vehicle, and it is interesting to note that several municipalities, realizing the importance of the newer method of transportation, have taken up the matter in a systematic manner. A. W. Robinson of the Locomobile Company of America, Bridgeport, Conn., has given this subject considerable study and the result of his findings are embodied in the following communication:

Editor, MOTOR TRUCK,

Sir:

Traffic conditions in congested portions of our large cities have been so greatly improved by the motor truck that it is not a wonder that so much co-operation has been obtained from the municipal authorities and from the heads of the various railroad and shipping companies. Today the owner of the motor truck finds conditions vastly improved over those of three years ago, but there is still room for improvements and for added facilities whereby the efficiency of the motor truck can be so increased as to result in a still further saving for the owner, for the municipality, and for the transportation companies.

The efficiency of a motor truck varies directly with the percentage of time during which it is transporting producing loads. Consequently, every minute lost, either through delays due to the congestion of traffic, through waits to get up to or away from a loading platform, or through the necessity of making detours to avoid streets which have been closed by the municipal authorities, all go to cut down the efficiency of the truck by preventing it from making the number of ton-miles, which under normal circumstances it should.

From the owner's viewpoint it is not reasonable to expect him to incur a large expense and make a heavy investment for motor trucks, each of which would supplant three two-horse teams, if such an investment is not a paying one. Various municipal and transportation officials realizing the immense advantage of the motor truck, and knowing that the motor truck is saving them large amounts of money through its relieving congestion, are co-operating with the owner to eliminate many of the delays which in the past proved so alarming.

Municipal authorities find that motor traffic has, from their viewpoint, three great advantages over horse traffic. They find that the motor truck is less destructive on the street, reducing the maintenance charges of the street repair department; they know that the reduction of the amount of horse debris, due to the supplanting of the horse by the motor truck, not only effects a large financial saving but it also has resulted in a betterment of the public health, due to the more sanitary condition of the streets. They also appreciate the fact that the motor truck has decreased, for any given tonnage, the number of vehicles required, with a consequent relieving of traffic congestion at rush hours.

This last is a very important factor in municipal conditions today and can be better realized when it is known that the normal large capacity truck, which under ordinary circumstances will supplant three two-horse teams, not only occupies a space equivalent to about 30 per cent. of the actual length of three such teams and wagons but also, owing to its great flexibility and ease of control, it can follow closer to the vehicle immediately preceding it. As an actual fact, assuming that the traffic conditions in any given street are as congested as they are today, something over four times as much tonnage could be carried by a given point in a given time if all the traffic were carried on motor vehicles. Or assuming that only the same tonnage was to be transported, traffic conditions would be greatly relieved and congestion would be practically eliminated.

Municipal authorities are doing all they can to further this end by keeping the streets in better repair, and by giving the faster moving motor vehicles the preference wherever possible. It is probable that in the near future, the municipalities will co-operate further by opening many streets which are now closed to heavy traffic, and thus enable the truck to save time by eliminating detours which formerly were necessary.

Immense improvements have also taken place in the last few years at the railroad depots and at the wharves. Where formerly the motor trucks were compelled to take their place in line and gradually work up to the platforms, today many progressive officials, intent on serving the best interests of their own stockholders, have minimized traffic delays by providing special platforms for motor trucks only. Railroad officials, trained and educated in the handling of freight, traffic experts in the broadest sense of the word, realize better than anyone else the need of speed, and they welcome any innovation which tends to relieve any congestion on their own platform, and which diminishes the time in transporting goods from the factory to the shelves of the distributor. While the idea of reserving a platform for motor trucks only is a comparatively new innovation, railroad after railroad is adopting the idea as fast as conditions and expediency will permit, and the percentage of space so reserved is increasing far more rapidly than any one not thoroughly conversant with the situations would imagine.

The same conditions obtain at the wharves; steamship traffic men, owing to the greater intervals elapsing between their shipment, are far more troubled by freight congestion than are the railroad traffic men, and they appreciate the relief from congestion afforded by the motor trucks. The motor truck has been valuable to steamship men in another way. If a wharf can be quickly cleared and a new cargo as quickly put on the wharf, sailings can be more frequent without increased wharfage facilities, a very serious problem when the comparatively small number of good wharves and of really good ports is considered. Steamship men in their endeavor to take advantage of benefits accruing from the motor truck have done a great deal for the owner.

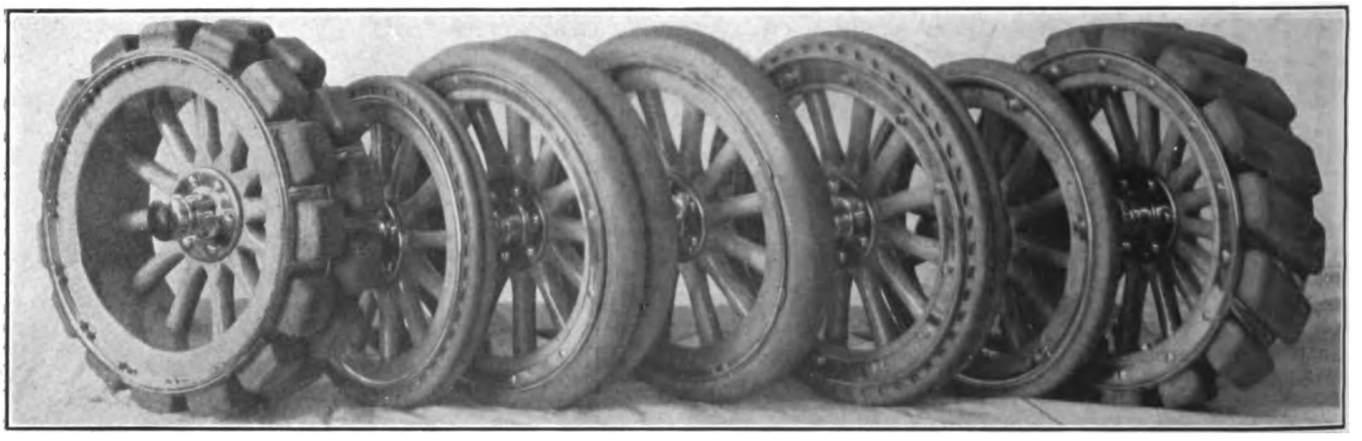
Digitized by Google

Only a few years ago, before the steamship men took an active interest in motor trucks, foolish fire regulations, since repealed, made it impossible to run a motor truck on a wharf in any of the large cities in this country, and it is only recently that wharves have been sufficiently well constructed as to stand up under a moving concentrated load as heavy as a large capacity motor vehicle.

The extent to which co-operation has been carried out might be continued indefinitely, but let it be sufficient to say that today every effort is being made to increase the scope and the field of the motor truck, not only by the manufacturer and by the user of these vehicles, but by all parties directly or indirectly interested in the great problem of transportation. Every improvement in traffic, depot or wharf conditions not only effects a saving for the truck user, the railroad man, or the shipping man, but also is of vital importance to the public at large. The public's interest lies in the fact that minimizing of delay means a lower transportation cost. Every cent saved in transportation between the producer and the user eventually results in a lower price for the user. While in the individual case this saving is not large, in the aggregate, an immense amount of money will be saved when traffic conditions are such that the majority of goods distributed in the various cities and towns, are transported on motor trucks.

Yours very truly,

A. W. ROBINSON,



Truck Sales Manager, Locomobile Company of America.
Bridgeport, Conn., March 13.

GOODYEAR TIRE LINE FOR 1912.

Tire manufacturers are keenly alive to the certainty of tremendous growth in the motor truck industry which is expected to equal that of the pleasure vehicle within the next few years. The Goodyear Tire & Rubber Company, Akron, O., has made preparations for its share of the business and has adopted for its slogan, "A Tire for Every Service." In the accompanying illustration is shown the Goodyear line for 1912 and these are, reading from the left to the right, the individual block, Goodyear-Motz cushion, Goodyear demountable, Goodyear metal base, Goodyear-Motz fire department and diagonal block tire.

Regarding the individual type, great stress is laid on the fact that one of the blocks may be removed and replaced without disturbing the other members. Each block has its own fastening plate and this device is extremely simple.

The demountable truck tire is furnished in the single as well as dual type and the Goodyear company emphasizes the claim that this style will be universally used shortly. The Goodyear demountable is recommended by its maker as simple of operation, guaranteed for 10,000 miles and adaptable to the S. A. E. standard wheel. The metal base tire is of the permanently attached type and finds favor with many truck owners.

Goodyear Truck Tires for 1912: Reading from Left to Right, Individual Block, Goodyear-Motz Cushion, Goodyear Demountable, Goodyear Metal Base, Goodyear-Motz Fire Department, Diagonal Block.

CONDITIONS GOVERNING TRUCK USE.

That the last two or three years have seen a marked change in the manner in which business men approach the purchase of trucks, is the opinion of C. P. Cary of the Peerless Motor Car Company, Cleveland, O., who has given much thought and study to this phase of the selling situation. He finds that the early vehicles were bought largely because the purchasers thought it would give them a reputation for progressiveness and would prove a good advertising expenditure. He says.

"Naturally, they knew nothing about trucks. A truck was a truck and they usually took the one that was represented by the most engaging salesmen. Those who happened to select a proper capacity vehicle found in most cases, that instead of being more expensive than horse delivery, as they rather expected, motor haulage really saved them a great deal of money, providing good men, who knew how to operate the vehicles and care for them properly, were secured. Those who purchased trucks not suited to the service, or who permitted them to be operated by poorly trained drivers, returned to the horse, or after much expensive pioneering found a suitable truck that would do their work economically.

"While the advertising value of commercial power vehicles has not entirely disappeared, it is a factor that is not longer regarded as greatly important by truck buyers. The truck when well made and given enough work to pay its way, performs an extremely valuable service. And as service over a considerable period of years depends upon construction, most buyers go rather carefully into the mechanical features of every vehicle that comes under their consideration."

J. M. WARD SUCCEEDS P. P. WILLIS.

J. M. Ward of the Waverley Company, Indianapolis, Ind., has been appointed to succeed P. P. Willis as secretary of the Indiana Automobile Manufacturers' Association. The appointment was announced recently by Frank E. Smith, general manager of the Maxwell-Briscoe plant at Newcastle, Ind. Mr. Willis resigned previous to the New York show and President Smith reserved naming a new official until recently. Mr. Ward is well known to the automobile industry.

MOTOR CAR EXPENDITURES.

According to a report filed by the police board of Hartford, Conn., the automobile expenditures from April 1, 1911, to Feb. 29, 1912, were as follows: Two patrols, $1355.39; ambulance, $528,66.

Digitized by Google

The Enterprise Trucking Company, New Haven, Conn., has been incorporated for $10,000.

The National Motor Transportation Company, Washington, D. C., has been incorporated for $1,000,000 to do a general transfer and passenger business.

J. K. McKeough, well known in the automobile industry, has accepted a position with the Chicago branch of the Velie Motor Vehicle Company of Moline, Ill.

The Stewart & Clark Manufacturing Company, Chicago, maker of Stewart speedometers, has leased a store and basement at 174 Columbus avenue, Boston.

The Motor Truck & Auto Company, Portland, Me., has been incorporated for $10,000. Lewis A. Goudy is named as president and George W. Merrow as treasurer.

Bishop & Whitney, operating a garage at Canaseraga, N. Y., has taken over the garage and taxicab business of Roberts & Son, Baldwin street, Elmira, N. Y.

James A. Williams, Boston, New England agent for the Cartercar Company, Pontiac, Mich., has leased the store and basement at 998-1000 Boylston street, Boston.

The Knickerbocker Motor Truck Manufacturing Company, New York City, is completing a new concrete factory building on East 150th street, near the Harlem river.

The M. M. Automobile Automatic Safety Signal Company, New York City, has been capitalized at $50,000. The incorporators include J. C. McGee, W. F. Rawlins and I. M. Black.

The Whitmore Auto-Gear Composition Sales Company, Jersey City, N. J., has been incorporated for $100,000. The incorporators include B. S. Mantz, J. R. Turner and L. H. Gunther.

The Victor Buggy & Top Company, St. Louis, Mo., has been incorporated for $2000 to deal in carriage and motor car tops. The incorporators include Oliver E. Carter, Roscoe Perdue and Frank Roband.

The Efficiency Supply Company of Boston has been organized with a capital stock of $5000. The officers are as follows: President, William H. Murphy; treasurer, Francis J. Coughlin, and M. F. Curran.

The N. S. W. Motors Company of Indianapolis, Ind., has been incorporated for $60,000 to manufacture automobile parts. The directors include Charles Nesom, Louis Sagalowsky and F. W. Wellman.

The Standard Tire & Automobile Company, Plainfield, N. J., has been capitalized at $25,000 to manufacture motor vehicle tires. The incorporators are as follows: H. P. Visseller, J. J. Slevin and F. Ivamy.

The Standard Tire & Rubber Company, Springfield, Mass., was incorporated recently for $10,000. The officials are as follows: President, William Cronin; treasurer, Wayne E. Hughes, and James S. Waddell.

The Los Angeles Automobile & Taxicab Livery, Los Angeles, Cal., has been incorporated for $75,000. The incorporators include Belle F. Lewis, Harty E. Jones, Evelyn Jones, Charles M. Lewis and William H. Lewis.

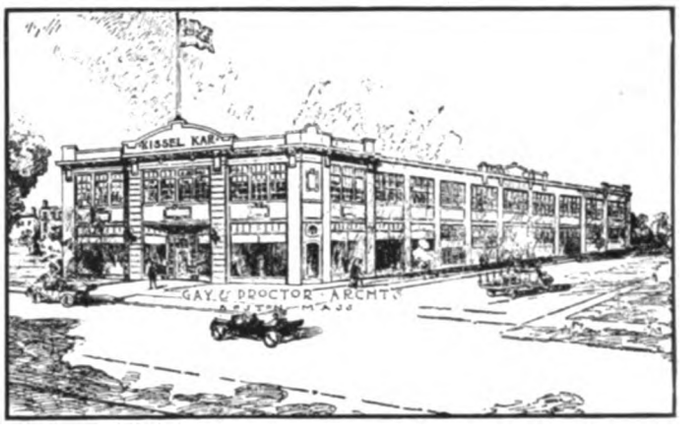
The Available Truck Company, Chicago, has been incorporated for $25,000 and will manufacture motor vehicles and parts thereof. The incorporators named are: E. F. King, A. H. Wiedhofft and R. C. Hume.

"Graphite," which publication is devoted to the interests of the Joseph Dixon Crucible Company, Jersey City, N. J., contains in the current issue, some interesting applications of graphite to the motor car.

The Corbin Motor Vehicle Company, New Britain, Conn., has completed a new ambulance for the city of Waterbury, Conn. It is equipped with modern conveniences and is propelled by a 40 horsepower motor.

The Essex Rapid Transportation Company, Boston, Mass., has been incorporated for $50,000 and will engage in a general trucking business. The incorporators include George E. Lovejoy, James J. Murphy and George B. Cook.

The Rowe Motor Company, Coatesville, Penn., will be reorganized in the near future under the name of the Rowe Motor Manufacturing Company, and will produce commercial vehicles in larger numbers than heretofore.



The Chase Motor Truck Company, Syracuse, N. Y., has completed a three-story addition to its plant, 80 by 140 feet. It will be utilized for the assembly of commercial cars.

The Baker Motor Vehicle Company, Cleveland, O., announces that it has secured the services of William P. Kennedy, the well known consulting electrical engineer of New York City to act as superintendent of the bureau of service efficiency.

The Copithorn Demountable Rim Company, Natick, Mass., has been incorporated for $100,000 to manufacture and sell tires and demountable rims. The incorporatros and directors include President Harry M. Ferguson and Louis C. Smith.

The Connecticut Telephone & Electric Company, Meriden, Conn., maker of Connecticut ignition specialties, announces the opening of an office, stock and show room at 231 West 54th street, New York City, where a full line of parts, etc., will be carried.

The Gramm Motor Truck Company, Lima, O., has an interesting and well illustrated special story upon the adaptability

New Home of the New England Branch of the Kissel Motor Car Company of Hartford, Wis., Which is Expected to Be Finished by Aug. 1.

of commercial vehicles to the furniture industry, in the February issue of "The Gramm," a publication issued by the Lima concern.

The Cleveland Taxicab Company, Cleveland, O., maintains a large fleet of these vehicles and in the accompanying illustration is depicted some of the automobiles in service. The cars are the product of the White Company, Cleveland, O., which makes a specialty of mechanical transports, both for passenger and freight service

The Morse-Readio Company, Springfield, Mass., has acquired a tract of land between Chestnut and Dwight streets and will erect a six-story building which will be of fire proof design. The concern handles the G. M. C. line of commercial vehicles, as well as pleasure cars.

Amos J. Shorey, northern Maine representative of the Velie line, has appointed Frank Mitchell sub-agent. The latter will establish a service station. J. T. Curtiss & Co., Velie agent for Simsbury, Conn., has closed with Tucker & Palmer of Tariffville, Conn., as sub-agent in that place.

The Lippard-Stewart Motor Car Company, Buffalo, N. Y., announces the appointment of the following new agencies: Neely & Ensor, Baltimore, Md.; Edward W. Jennings Company, Bridgeport, Conn.; Michigan Motor Company, Portland, Ore.; Whitten Motor Vehicle Company, Providence, R. I.

Digitized by Google

The Lauth-Juergens Motor Car Company, Fremont, O., has decided to add to its capital stock and to utilize the proceeds in increasing the output by erecting large additions. A branch factory will be constructed at Gibsonburg, where the residents have subscribed for $50,000 worth of stock.

The Amalgamated Motors Corporation, Los Angeles, Cal., has been incorporated for $1,000,000. The directors include W. M. Varney, C. B. Croner, Robert McKee, Ernest Kouwenhoven, R. P. Craig, C. L. Woodbury, R. F. Davis, L. Scheer, C. F. Schroeder, J. A. Craig, T. W. Beddo, J. L. Kirkham, Thomas Carmody, Jr., J. B. Price and N. E. Masson.

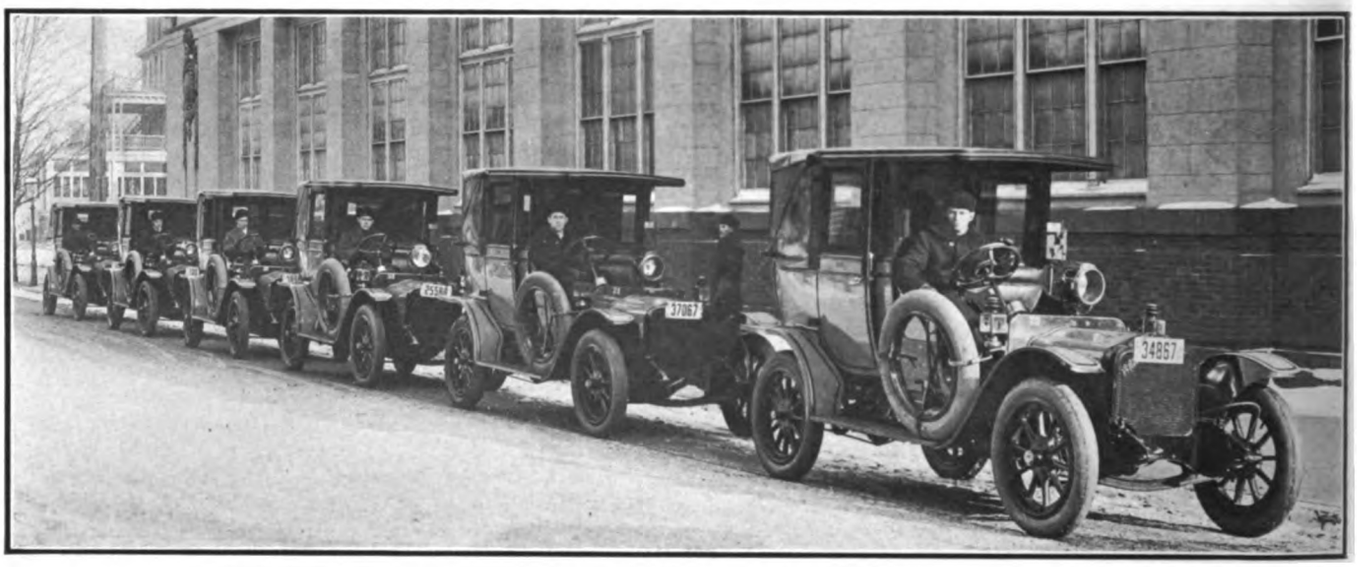
James Drummond of Newburyport, Mass., has become identified with the Drummond Motor Car Company of Omaha, Neb., which concern will move into its new building at 324 South 18th street, about May 1. The company is agent for the G. M. C. trucks, and the officials are: President, W. R. Drummond; vice president and general manager, James Drummond; treasurer, L. W. Schieble; secretary, W. B. Hughes.

Fred J. Titus, who for the past year has been connected with the retail department of the American Locomotive Company of New York City and Providence, R. I., is now associated with the wholesale department. He is well known to the automobile trade having left the bicycle industry for that of motor cars when the latter was in its infancy.

The Remy Electric Company, Anderson, O., announces that arrangements have been made whereby Child, Day & Churchill, Inc., Spokane, Wash., the Washington Auto Supply, Seattle, and the Archer & Wiggins Company, Portland, Ore., will act as Remy service stations in their respective cities. Each will carry a full complement of the Remy ignition products as well as retain a corps of skilled experts.

The Parker Transmission Appliance Company, Springfield, Mass., which is capitalized for $1,000,000 to manufacture a device to eliminate the friction between gears, expects to occupy new quarters on the top floor of the Hunters Arms factory shortly. The product to be manufactured is the invention of Clark Parker of Springfield, and the transmission and clutch are of the constant mesh type.

The Horst & Strieter Company, Davenport, Ia., announces the opening of a new garage at 1417 Second avenue, where special attention will be paid to the care and maintenance of trucks. The company handles the G. M. C. line, manufactured by the General Motor Truck Company, Detroit, and maintains a service station for these vehicles. Henry W. Horst is president of the Davenport concern, Henry T. Horst, vice president, and M. E. Strieter, secretary and treasurer.



W. E. Darrah, president of the New Hampshire Auto Company, Concord, N. H., has closed with Robert Kayser of the Velie Boston branch for the Velie agency in Concord and vicinity. A service station has been established. Walter Velie Johnson, Essex Junction, Vt., will represent the Velie commercial and pleasure line for 1912 in that place. He maintains service stations at Burlington and Essex Junction.

The Wayne-Haven Motor Car Company, New Haven, Ind., was organized recently with a paid up capital stock of $25,000. It was decided to move the machinery of the Woodburn Auto Company to New Haven and install the apparatus in a new factory building which will permit of a larger production of trucks. At the meeting the following officers were elected. President, Allen M. Hartzell; vice president, Sherman H. Grubb; secretary-treasurer, Samuel J. Stocks. The directors are Conrad Buhr, Allen J. Pond, Herman Messman, William F. Keller and Jonah Adams.

The P. H. P. Motor Truck Company of Westfield, Mass., has been acquired by W. S. Magill, Guy Osborne and I. P. Miller, all of New York, and will be reorganized as the Westfield Motor Truck Company with a capitalization of $150,000, of which $50,000 will be preferred stock. The new company will continue in Westfield and plans to build 300 machines this year. The original truck was designed by Dr. A. B. Pendleton and its manufacture has been carried on for over a year. The Atlantic Motor Truck Company of New York City will have charge of the sales in New York and vicinity.

C. F. Splitdorf, New York City, maker of ignition specialties, has issued an interesting brochure containing a resume of the performance of cars equipped with Splitdorf ignition in competition on road, hill and track, which provides a useful reference work of racing performances in general and the 1911 season in particular. The records are exhaustive and authentic and with numerous illustrations bring out the Splitdorf victories, including world's records, etc. A free copy of the booklet may be obtained by applying to C. F. Splitdorf, 138th street and Walton avenue, New York City.

The Schildwachter Carriage Company, Park avenue and 128th street, New York City, has taken over the exclusive eastern agency for the Sternberg trucks, made by the Sternberg Manufacturing Company, Milwaukee, Wis., which concern makes two, three, four and five-ton power wagons. In addition to the Sternberg the Schildwachter Carriage Company is agent for the McIntyre line.

Fleet of White Taxicabs, Made by the White Company, Cleveland, O., in Service with the Cleveland Taxicab Company of That City.

The Mais Motor Truck Company, Indianapolis, Ind., announces the resignation of C. H. Wallerich, general sales manager. He has been identified with the automobile industry for several years, having been connected with the makers of Marion, Haynes and Overland cars. It is stated that he has accepted a position as manager of the automobile department of the newly organized General Industrial & Manufacturing Company. The latter was incorporated recently for $1,000,000 and will produce delivery vehicles of 1000 and 1500 pounds capacity. T. B. Laycock, a well known manufacturer of Indianapolis, is president of the concern.

The Kissel Motor Car Company, Hartford, Wis., is erecting a new home for its New England branch at Commonwealth avenue and Pleasant street, Boston, of which H. B. Pruden is manager. The new structure will be 74 by 200 feet and will be equipped with modern conveniences for the care and maintenance of the product of this concern. The plans call for an exceptionally fine salesroom, which will have a frontage of 74 feet and a depth of 70. The garage will occupy the rear of the first floor and here modern appliances will be installed. Directly off this will be a room for the chauffeurs. The service shop will be located on the second floor where up-to-date machinery will be operated by electricity. A feature will be the fitting of a trolley system for handling of heavy parts. The front portion of the second floor will be utilized as a display room for commercial cars. The building is expected to be ready for occupancy about Aug. 1, and in the accompanying illustration is depicted the architect's drawing of the structure.

TRUCK REGISTRATION IN MASSACHUSETTS.

IN RESPONSE to a special message from Governor Foss of Massachusetts, the sub-committee of the legislative committee on highways and bridges has formulated a bill, in which the fees for registration in that commonwealth are to be increased materially. The proposed legislation contemplates the following: From five to 10 horsepower, 30 cents a horsepower; 10 to 29, 40 cents; 30 to 39, 50 cents; 40 to 49, 75 cents, and 50 and over, $1. The Massachusetts State Automobile Association has undertaken to defeat the bill, President L. R. Speare having addressed a letter to the various motoring organizations in the state, his reference to motor trucks being as follows:

"In regard to commercial vehicles: We are informed that the same rate is to apply to these. This is manifestly unfair. After a great deal of consultation with different manufacturers of motor trucks we do not believe that horsepower is a fair scale to work on in regard to commercial vehicles. The proposition is a different one from that of pleasure vehicles. Some five-ton trucks, for example, have 35 horsepower, some have 40 and some 48.6. Each carries the same load and makes the same rate of speed.

"Manufacturers agree that 12 miles an hour is the speed that a truck should make, and that it should not be driven at a higher rate. If the 48.6 horsepower truck were rated at 49, the fee would be $36.75, the 40 horsepower would pay $30 and the 35 horsepower would pay only $17.50, while doing equal damage to the roads in every respect. In other words, the 48.6 horsepower motor truck is obliged to pay more than twice as much as the 35 horsepower truck, simply because it has a larger engine. It goes no faster, carries no larger load and does no more damage to the road.

"We have, therefore, suggested the following scale for motor trucks, which would make an enormous increase in the amount of registration, and it seems to us would be much fairer than the scale proposed: One ton, $5; two, $7.50; three, $10; four, $12.50; five, $15; six, $17.50; seven, $20; eight, $22.50; nine, $25; 10, $27.50; over 10 tons, $50.

"It is doubtful if a motor truck will be built that will carry over 10 tons, but if the manufacturers should conclude to put on a jumbo we believe they should pay for it, as the roads are not fit to carry over a 10-ton load at the present time. The fee would be based upon the tonnage guaranteed by the manufacturer for the truck. He could not guarantee it to carry a small amount, as he would not be able to sell the truck, and the tax would not be so large that there would be any object in so doing."

FEDERAL TRUCK HAULS FIRST LOAD.

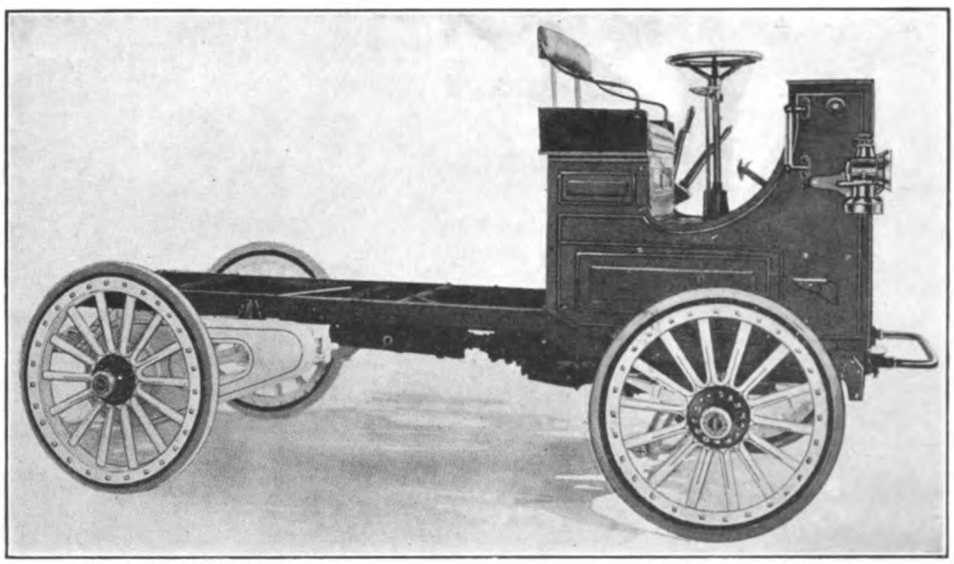
Work has been commenced upon the site for the International Panama-Pacific Exposition which will be held at San Francisco, Cal., in 1915. The first load of lumber to be delivered to the ground was furnished by the San Francisco Lumber Company which utilized a Federal truck, made by the Federal Motor Truck Company, Detroit. In the accompanying illustration is depicted the machine about to start on its trip to the exposition grounds.

The car is propelled by a four-cylinder, four-cycle, water-cooled motor of the L head type having a 4.25-inch bore and 4.5-inch stroke and is rated at 30 horsepower. Ignition is by an Eisemann high-tension magneto and lubrication is by constant level splash and gear pump.

A leather faced cone clutch is employed with auxiliary springs and power is transmitted through a selective sliding gear providing three speeds forward and reverse. Final drive is by side chains. The front axle is of the I beam section type and the rear member square. Timken bearings are employed. The tires are solid, 36 by 3.5 inches front and 36 by four inches rear. The driver's position is at the left with left hand control.

Federal Truck Hauling First Load of Lumber to Panama-Pacific Exposition Grounds at San Francisco, Cal.

NEW YORK'S ANNUAL PARADE.



Preparations for the annual commercial vehicle parade in New York City under the auspices of the Motor Truck Club, April 13, are progressing satisfactorily, and the committee reports that it already is assured of more cars than have ever taken part in a similar event in this country. Most of the leading dealers have shown a disposition to co-operate with the club in the enterprise and have urged their customers to join in the plan. Entirely aside from the trade, however, the club is anxious to get as large a representation of individual owners as possible, and to this end a special invitation is issued to all owners, the committee according these a broader opportunity for advertising their own business than the dealers themselves. The chief object is to make an effective showing of motor truck representation in this centre, as an encouragement for the extension of commercial vehicle use.

FEATURES OF SANDUSKY 3000-POUND WAGON.

THE Sandusky 3000-pound delivery wagon, built by the Sandusky Auto Parts and Motor Truck Company, Sandusky, O., is designed with a view of minimizing the time required for care and attention, this economy being possible through unusual accessibility and simplicity of construction without the sacrifice of any desirable quality. Only one type is now built, but the company is to produce, as soon as this can be brought about, a lighter and a heavier vehicle, which will be practically of the same design.

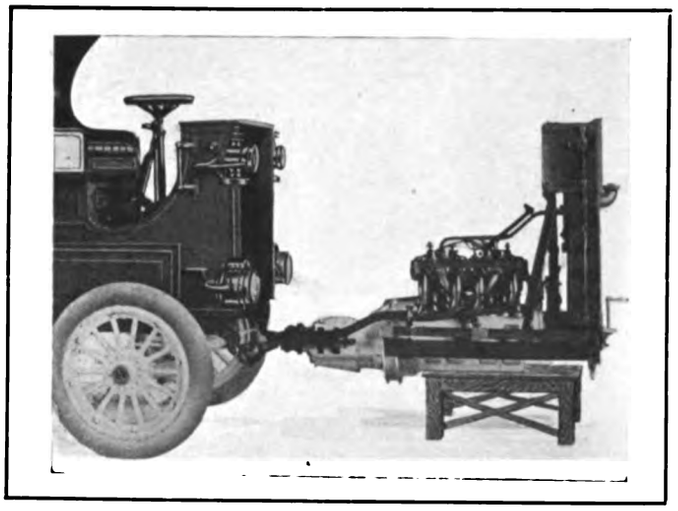
The chief feature is in the manner of installing the unit power plant, which can be withdrawn from the chassis in 10 minutes without the use of special facilities or tools and by one man. The replacement may be made in no longer time and without assistance. A spare engine and auxiliaries may be installed in a vehicle frame, replacing one that may be inefficient, in 20 minutes. This means that with an extra power plant the owner of several wagons will always have a reserve that would not be possible with machines of conventional construction. There is nothing freakish in the design. It is based on sound engineering, and there is a margin of safety in every respect.

The Sandusky Model C Delivery Wagon Chassis, with Load Capacity of 3000 Pounds.

The motor, clutch and transmission as a unit is mounted in a sub-frame whch also carries the radiator and gasoline tank and their connections. The exhaust manifold connection with the muffler is telescopic, and the driving shaft is so coupled with the transmission shaft that by the release of a retaining sleeve the coupling may be dropped. The lifting of the steering column and the disconnection of the clutch and speed change levers leaves the assembly free in the chassis frame. Then by raising six spring-controlled plungers and operating two levers that lower the sub-frame onto rollers, the frame and power plant may be drawn out of the chassis frame. Placed on blocks or horses work may be performed with the best of light and without obstruction. Every part is absolutely free to the workman. When work has been completed the sub-frame is installed in the chassis by a reversal of the process outlined.

It is claimed by the maker that the materials used are of the highest quality, 3.5 per cent. nickel steel, chrome nickel steel and vanadium steel being employed for all purposes where steel would ordinarily be utilized. All parts are machined to exact gauge with special machine tools, insuring accuracy of work and interchangeability of parts. Thorough inspection makes possible the maintenance of this standard of production, both in the components and the assembled work.

The motor is a four-cylinder, water-cooled, four-cycle L head type with bore of 3.75 inches and stroke of five inches. This is rated at 22.5 horsepower by the S. A. E. standard formula, but will develop considerably in excess of this being specified as 25-30 by the maker. The cylinders are cast en bloc and with the heads and the water jackets integral. The valve pockets are at the right side. The water jacketing is unusually large and the greater part of the outer wall of the cylinder heads above the combustion chamber is in the form of cast cover plates, each pair of cylinders being served by one plate. The cylinders are cast of a soft gray iron of superior grade. The core sand may be thoroughly removed through the large water jacket vents, this construction obviating the possibility of obstructions to circulation and facilitating cleaning or repair. The cylinder block is bored, reamed and after ageing is ground to precise diameter. The water jacket cover plates are fitted and the water tight joint is insured by gaskets, each plate being held by a pair of hollow studs that are centred in the combustion chambers. Into these studs are fitted the compression relief and priming cocks. The cylinders are offset .75 inch with reference to the centre of the crankshaft.



The pistons are cast of a special gray iron and after turning are ground to the exact size. The pistons are channeled to limit gauges for four .25-inch rings that are bored eccentric and are ground on both edges and the peripheries to the gauged size. Extreme care is taken to insure perfect castings.

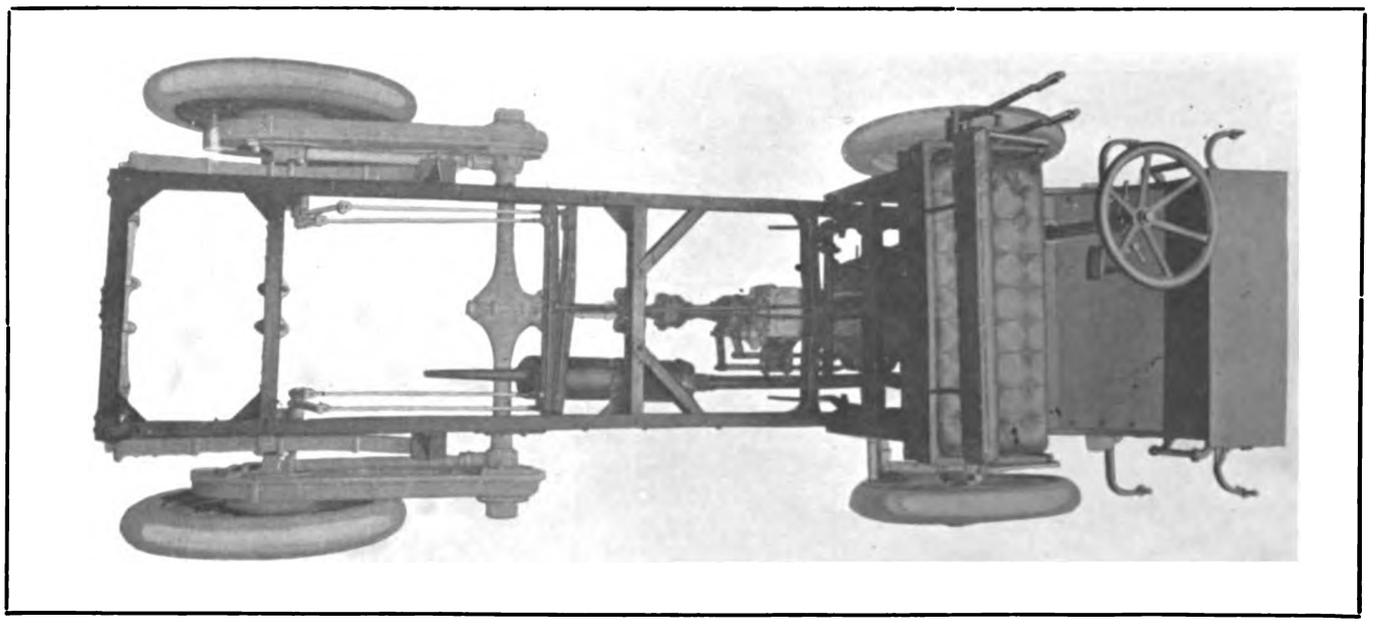
The crankcase is in three sections, these being the upper and lower halves of the barrel and the cover or case for the timing gears fitted at the front, but the rear ends of the case are extended to form the housing for the flywheel, and to the heavy flange at the end of the extension is bolted the housing for the clutch and transmission assembly. There are two large handholes at the top of this rear case above the clutch and the transmission. This casing when assembled contains the entire mechanism of the power plant. The material used is an aluminum alloy that has extreme strength. At the forward end of the crankcase and at either side of the flywheel case are very strong arms that support the assembly in the sub-frame, they being bolted to the sturdy side members.

The upper crankcase section is divided by a transverse web of heavy section and is strengthened by bridgework. The lower half is similarly divided with compartments directly beneath each crankthrow, and contains the oil reservoir. The top half ends and the central web carry the large main bearings, the camshaft and its bearings, the timing gears and their housing.

The crankshaft is a special analysis nickel steel drop forging with the flywheel flange forged integral, which is heat treated and is ground to limits for all bearings. The shaft bearings are of large diameter and length and are of a fine quality of bearing metal. The bearings are retained by heavy bolts and castellated nuts, four at each

Digitized by Google

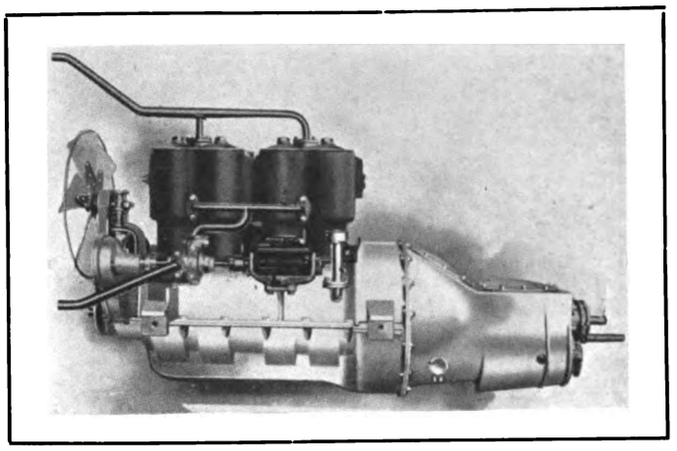
Unit Power Plant of Sandusky Delivery Wagon Withdrawn from the Chassis for Examination.



end and two at the centre bearing. The camshaft is special analysis nickel steel drop forging with the cams integral. This is hardened and ground to limits, this insuring the size of the three bearings and the accurate formation of the cams and certainty of valve timing.

The connecting rods are steel drop forgings of I section that are fitted with die cast phoenix metal bearings at the crankpins and with bronze bearings at the wristpins. The wristpins are steel tube, carbonized, hardened and ground and are fitted into the piston bosses and retained by large cotter pins. All pistons, wristpins and connecting rods and their bearings, are weighed and, when assembled, perfect balance of the reciprocating parts is insured. The valves are of large size to obtain positive exhaust of the burned gases and to secure adequate charges of the fuel gas. The heads are of 3.5 per cent. nickel steel welded electrically to carbon steel stems. The valves are accurately ground and the stem ends are case hardened. The valve lifters are of steel and the cam contacts are steel rollers, hardened and ground, revolving on hardened steel pins. The valve stem contacts are fitted with adjusting screws and lock nuts and with fibre inserts to eliminate noise. The valve lifters are set in die cast guides that are held in the engine case by crab yokes. The valve guides are iron castings pressed into the cylinders. These guides can be replaced when worn. The timing gears are with wide faces, that at the right side driving the camshaft, and that at the left side driving the water pump, an outside extension of this shaft driving the magneto.

The engine is cooled by the circulation of six gallons of water through the large jackets of the engine, forced by a centrifugal water pump of unusual size. The water enters the cylinders at the base of the jackets through a two-way inlet and the liquid is directed around the cylinders, and then flows outward through a manifold with outlets located in the centre of the twin cover plates over each pair of cylinders. The manifolds are copper tube with rubber unions. The water is cooled by a tubular radiator of stout construction and radiation is increased by a six-bladed aluminum fan that is carried on a bracket located forward of the cylinder block. This bracket has a block carrying the ball bearing for the fanshaft that is supported by two strong helical springs surrounding the guides for the block. The fan is driven by a flat belt from a pulley on the crankshaft extension and any lengthening of the belt through wear or stretching is compensated by the springs supporting the fanshaft bearing block.



The lubrication of the engine is by splash with flywheel distribution. The reservoir integral with the base of the crankcase is filled with oil and this is so designed that a limited quantity flows into the base of the compartment in which the flywheel revolves. This oil is carried upward by the flywheel and drains into a series of ducts cast in the upper and lower sections whence it is distributed to the pits under the crankthrows. The sweep of the connecting rod ends into the oil pits causes a spray of oil to fill the engine case, lubricating the main, camshaft, connecting rod and wristpin bearings, the cams, valve lifters, the timing gears and the cylinder and piston walls. The timing gear on the crankshaft is driven in an oil pocket and from this the other gears are constantly lubricated. The excess oil is drained into the oil reservoir and is again carried through the system.

The ignition is by a high-tension Mea magneto that is driven by a coupling from the water pump shaft. In this instrument the advance or retarding of the spark is accompanied by rocking the magnets, which produces a uniform spark at all speeds. It is claimed that there is no position of the ignition lever at which the engine may not be started by the magneto without difficulty and for that reason there is no other means of ignition necessary. But one set of

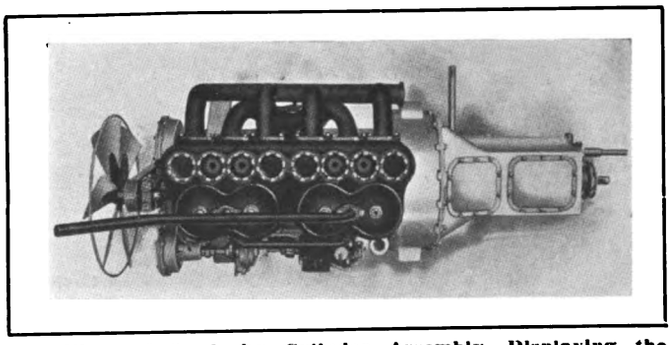
Digitized by Google

Left Side of the Sandusky Unit Power Plant, Showing Water Pump, Magneto and Fan Bracket with a Spring Maintained Belt Tension.

spark plugs is used with this installation.

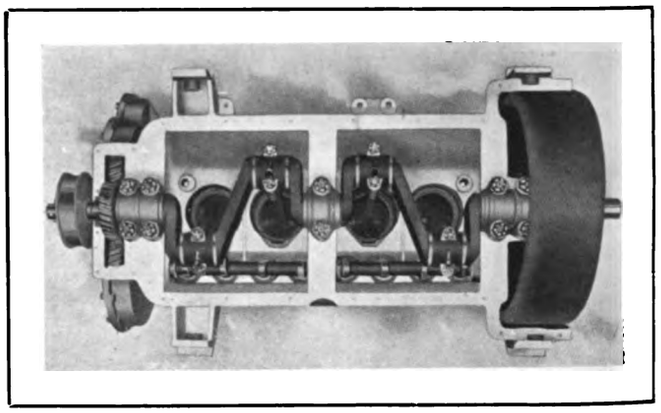


The carburetor is a float feed automatic type that will produce a uniform quality of gas at all engine speeds. The inlet manifold is very large and with straight leads to each pair of cylinders, the fresh gas sweeping the electrodes of the spark plugs and cooling and cleaning them. The distribution of gas is very even. The fuel is fed by gravity from a tank of 12 gallons capacity. The radiator is carried on spring supports in a frame at the front end of the sub-frame on which the power plant assembly is installed. Above this and similarly mounted on springs is the gasoline tank. The connection with the carburetor is a large copper tube in which is a strainer and shut-off cock. There is a sight feed gauge on the dash that shows the quantity of fuel remaining in the tank.

The clutch is of the cone type. The cone member is faced with asbestos fabric that cannot be affected by heat and its efficiency is not impaired by saturation of oil, while there is a cushioning effect at engaging caused by flat springs beneath the facing, that insures against all jars and jolts. The clutch spring is strong but the operating levers are so compounded that its operation is very easy.

The transmission is a selective design giving three forward and one reverse speeds. Both the driving and the counter shafts are of chrome nickel steel, hardened and ground, and they are mounted in high grade annular ball bearings. The gears are 3.5 per cent. electric furnace nickel steel, with broad faces, long hubs and accurately cut stub teeth of large pitch. The fixed gears are keyed to the shafts.

This entire assembly is carried by the sub-frame and by the removal of the sub-frame from the chassis in the manner described, work may be performed on any one of the groups without breaking any connections and without disturbing the relations of the different members. No tools or wrenches are necessary.



The transmission driving shaft is coupled to the main

Top View of Sandusky Cylinder Assembly, Displaying the Large Plates Covering the Water Jackets and the Flywheel and Transmission Cases.

driving shaft by a movable sleeve or collar that may be quickly disconnected. Back of this is a universal joint, then the main shaft, a second universal joint and then the pinion shaft. The shaft is supported from the centre cross member of the chassis frame. The drive is by a pinion and bevel gear to the jackshaft. The jackshaft housing is pressed steel. The differential cage is mounted on Timken roller bearings that are adjustable. The driving shafts are chrome vanadium steel, heat treated. The final drive to the dead rear axle is by double side chains that are enclosed in dust and water tight cases that are packed with grease. The operation of the chains is noiseless.

The chassis frame is a special design of chrome nickel steel, channel section, two inches depth and four inches width, .125 inch thickness. It is well braced by cross members and gusset plates. It is dropped in front to carry the sub-frame of the unit power plant. The front springs are semi-elliptic, 40 inches length and two inches width, with 10 leaves; the rear springs are three-quarters platform, the side members being 40 inches length and two inches width and the end member 36 inches length and two inches width, eight leaves, with an auxiliary spring over the rear axle 36 inches length and two inches width, of six leaves. All springs are vanadium steel. The rear axle is a rectangular drop forging of 3.5 per cent. nickel steel with the wheel spindles fitted with Timken roller bearings. The front axle is a similar forging with Elliott type yokes with a roller

Bottom View of the Sandusky Engine Case, with the Big Main Bearings and the Spiral-Cut Timing Gears.

thrust bearing at the top of the steering knuckle. The wheel spindles are fitted with Timken roller bearings of large size. All the wheels are fitted with cast steel hubs with generous flanges at the spoke butts. The relation of the rear axle is preserved by heavy radius rods that are attached to the rear axle and to the jackshaft housing. The wheels are artillery type, with 14 spokes, and are 40 inches diameter for solid tire equipment and 36 inches diameter for pneumatic tires.

The control is by a hand wheel at the top of a vertical steering column that can be lifted from its connections for the removal of the power plant, by a clutch pedal and a service brake pedal, hand levers that change speed and operate the emergency brake, and fuel throttle and ignition levers mounted on the steering column below the wheel. The steering connection is a double screw type of substantial construction, all wearing parts hardened, with adjustments for compensating wear. The brakes are internal expanding, the shoes being faced with thermoid. The brakes are large and have great endurance. The drive is at the left side and the hand levers are mounted at the side of the driver's seat outside the frame. The speed of the wagon is 15 miles with solid tires and 20 miles an hour with pneumatic tires. The wheelbase is 106 inches and the tread 56 inches. The turning radius is 40 feet. The loading platform is from 42 to 56 inches width and eight to 10 feet length. The normal capacity is 3000 pounds.

MACK IN NEVADA MINING SERVICE.

The Jersey Valley Mines Company, Battle Mountain, Nev., has been operating a Mack truck, made by the International Motor Company, at its Mack plant in Allentown, Penn., in mining service during the past year, and the result of this experiment, for such it was regarded by the owner, is told in the following extracts from a letter from William F. Pinkham of the mining concern:

"To begin with: The truck, loaded at Newark, N. J., arrived in good shape, 14 days after shipment. We immediately filled the gasoline tank, started it on the second turn of the crank and began clearing the freight yard of the accumulation of mining machinery, lumber, provisions, etc. All of the adjustments were perfect as sent from the factory. The following day we gave it a trial with distillate as fuel, the only adjustment necessary being the addition of a hot air intake carburetor, leading directly around the exhaust pipe, this being required for the proper vaporization of the heavier fuel.

"Our first trip over the desert road was one of construction. We fastened behind the car a drag made of two nine-foot lengths of 90-pound railroad rail, and dragged this over the 46 miles of road to the mines, a gang of four men following to remove loose stones, etc. This was an attempt to smooth the road and fill the deep ruts made by the freight wagons, in which we were successful, but as there has been no rain in this country since April 16 all the soil we filled into the ruts is now a mass of fine dust, through which we plow to a depth of 12 to 14 inches in many places.

"It is hard, unless one actually has travelled over these desert roads to imagine just what they are like, particularly as you have nothing like them in the East, and I give you this description, as it is of course necessary in order properly to appreciate the performance of the truck.

"Our road lies down the length of a valley with high mountains on either side, and in the month of March, when the snow melts rapidly from the mountain sides, many brooks and small rivers flow down into the valley and across our roadway, with the result that after years of this treatment, the road is crossed by many gullies and brook beds from three to 10 feet deep, few of which have banks less steep than 45 degrees. This is the usual condition of all the roads throughout this state, and is considered inevitable, although in time we hope to improve this particular road greatly.

"Our running time has been 9.5 hours going out with a load and seven hours coming back empty. The time taken by a mule team with a six-ton load and 12 mules, is three days going and two days coming back, the freight charge being $20 a ton. A day's rest is necessary between loads. Therefore, while the mule team is delivering six tons, we can deliver 15 tons with the truck. The difference in cost a ton can be imagined easily.

"As far as the power goes, we could cut the above time much further, but would consider it rank abuse of a good machine to do so with the present roads. In fact, had we not such an accumulation of freight whch is needed at the mine, we would keep the truck off the roads entirely, until we could get rain to harden them and make travel more comfortable."

STANDARD OIL BUYS G. M. C. TRUCKS.

One of the best arguments in favor of the commercial vehicles is the fact that large corporations are replacing their horse drawn equipment with the mechanical transport. These concerns watch operating expenses very closely. They must be kept to a minimum and the adoption of trucks means that the heads of the companies have investigated the automobile and are satisfied that it is both efficient and economical.

The Standard Oil Company has placed a large number of trucks in operation at its different branches and recently installed a fleet of 3.5-ton G. M. C. trucks, made by the General Motors Truck Company, Detroit. In the accompanying illustration is depicted one of the machines of the fleet installed at Kansas City, Mo. Specially constructed sills are fitted to the frame for the purpose of carrying large oil tanks as will be noted in the picture.

The driver is protected from the weather by an ample sized cab which is enclosed by means of curtains, and a feature of the construction of the top is a projecting bonnet, which, like the top, can be folded back. The vehicle is propelled by a four-cylinder, four-cycle, water-cooled motor having a five-inch bore and five-inch stroke, rated at 40 horsepower. A feature of the power plant is that it is removable, being mounted upon a main sub-frame. Ignition is by Mea magneto with storage batteries in reserve and dual ignition is provided by two sets of spark plugs. Lubrication is by splash. A multiple disc clutch is utilized with a progressive type of transmission, this providing three speeds forward and reverse. Final drive is by side chains. Two sets of brakes are fitted, of the expanding and contracting type, these being located on the rear wheels. The front springs are semi-elliptic with platform at the rear, and an auxiliary member is also fitted.

One of a Fleet of 3.5-Ton G. M. C. Trucks in Service with the Standard Oil Company at Kansas City, Mo.

NEW MOTZ TIRE AGENT.

The Motz Tire & Rubber Company, Akron, O., maker of Motz tires for gasoline and electric commercial and pleasure vehicles, announces the appointment of the Standard Tire & Rubber Company, 104-106 Portland street, Boston, as its representative in that city and vicinity.

Digitized by Google

EFFECT OF SPEED ON TIRES.

Experts interested in the commercial vehicle because of its economic possibilities are agreed that the driver who throws discretion to the winds and operates his truck at an unreasonable speed is unquestionably the most expensive feature of the maintenance account. Tire manufacturers, in particular, attack the speeding driver and his methods. They argue that speeding is by all odds the most important of all deteriorating influences to which tires are subjected. Commenting upon this situation, F. F. Phillips, manager of the solid tire department of the United States Tire Company, New York City, says:

"Beyond any question of doubt, the speed maniac is a menace to the truck industry. Putting aside every other consideration—wear and tear on machinery, endangering the lives of pedestrians and violation of sane traffic rules—the speeder is an undesirable party for the reason that he costs his employer a great deal of unnecessary money.

"It makes no difference how well solid tires are made or to what extremes the manufacturer goes to fortify them against the incessant knocks of road travel, they will not withstand the abuses of the speed maniac. Speeding is an evil that can result in but one thing—decreased tire mileage and increased tire expense.

"Demonstration has proved that at an average speed of 12 miles an hour the life of a tire is about twice what it is at an average speed of 20 miles an hour. Still higher speeds reduce the life of the tire proportionately. Therefore it should not require any great amount of meditation to determine the effect of constant speeding upon the owner's tire bills.

"There are a great many conditions and abuses calculated to shorten the life of a solid tire, but of all these I have no hesitancy in placing speeding at the top of the list. Every manager of a motor service should insist upon strict observance of moderate speeds. Economical tire service can be secured in no other way.

"As a simple illustration of the effect of fast driving on solid tires, take two locomotives travelling at a speed of say, five miles an hour, and bring them into collision. The result is not serious. However, if you take these same locomotives, travelling at the rate of 30 miles an hour, and jam them together, something is bound to happen. It is the same with solid tires. When a moderate speed is maintained, road obstructions are of slight consequence, but when the truck is sent along at a fast rate, the reverse is true."

KNOX BUILT FIRST TRUCK.

What is claimed to be the first gasoline motor truck was the three-wheeled delivery wagon constructed for the department store of Smith & Murray at Springfield, Mass., by the Knox Automobile Company of that city, in 1901. However, the owner of the first rubber tired motor truck was the Adams Express Company, which ordered a Knox truck for delivery in Worcester, Mass., Nov. 2, 1903, and a second one of the same make for New York City the following day.

Two of the earliest owners of Knox three-wheeled cars were men who have become famous as automobile designers. One of these was C. R. Creuter, designer of the Matheson, and the other, Charles Y. Knight, inventor of the Knight motor. The machine built for Smith & Murray in 1901 was the forerunner of a rapidly growing commercial vehicle business, and an offshoot is the fire apparatus line which has developed with leaps and bounds, until today nearly every large community in the country has one or more pieces while several cities and towns are completely changing over their equipment.

BRUSH FOR RURAL CARRIER.

In an effort to determine the relative cost of the automobile and horse equipment in rural mail delivery, a carrier on one of the routes leading out of Eldorado, O., recently selected a Brush runabout, made by the Brush Runabout Company, Detroit, a constituent of the United States Motor Company, with which to make the test. He found that the actual cost for gasoline and oil for the trip was 14 cents as against 60 cents for the horse and wagon.

In the first place it should be stated that the distance to be covered was 26.25 miles, and that 125 stops had to be made. The automobile completed the task in 2:35:00, while the horse needed approximately six hours. It will be seen that not only will the Brush runabout do this work at a saving of more than 200 per cent. in expense, but will give the carrier some three extra hours each day. He proposes to utilize the car in the livery business after finishing his day's work for the government.

ECONOMY AND EFFICIENCY.

Talk to a man in real figures and he will listen every time, especially if those figures refer to the cost of operating motor trucks. It is pretty generally recognized by commercial vehicle manufacturers today that it is an actual illustration of service cost under average conditions which makes its appeal, combined with a proved statement that the truck will cover more territory in a given time and consequently carry more goods. Here is an instance:

The Acme White Lead & Color Works of Detroit has had in operation for some time a five-ton G. M. C. vehicle, made by the General Motors Truck Company of that city, and since its installation has been keeping a strict account of its performance and operating cost. A statement issued recently by it proves interesting not only from an economical standpoint, but the comparison made with the horse system clearly emphasizes the advantages of the motor truck and the saving and efficiency resulting from its use. This particular G. M. C. took the place of two teams and two men, but for a month both systems were in operation in order to make the comparison.

While the two teams were only able to carry 250 tons of material during the month, the truck during the same period carried loads aggregating 780 tons, or three times more than the amount drawn by the horses. As to the territory covered, and this is one of the very important items, the teams negotiated 1144 miles against 1430 for the truck. It will be seen that the mechanical transport was able to cover a third more territory than the two teams.

The biggest surprise, however, was in the matter of expense. It took $229.16 to maintain the two teams, pay the drivers' wages and feed the horses. The motor truck involved an expenditure of $152.10. This included wages of driver, gasoline and oil. To summarize, it not only cost $77.06 less to maintain the power vehicle, but it was possible to cover 286 more miles and carry 530 more tons of material.

LAUNDRY BUYS VELIE CAR.

There is a growing tendency among laundries to adopt the commercial vehicle. The automobile has proved its efficiency and economy in this work where the deliveries are not confined to a few sections in the city. The Union Laundry Company of Worcester, Mass., recently experimented with motor cars and the results were so gratifying that an order was placed with the Acme Motor Car Company of that city for a Velie truck, made by the Velie Motor Vehicle Company, Moline, Ill.

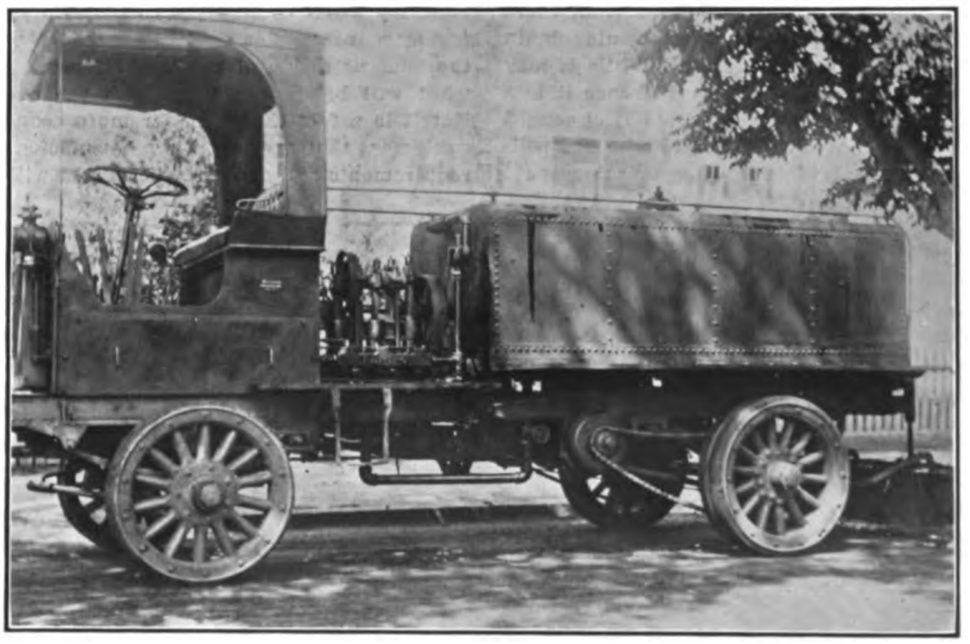
Devoted to Motor Driven Business Vehicles of All Classes.



VOL. III. PAWTUCKET, R. I., MAY, 1912 No. 5

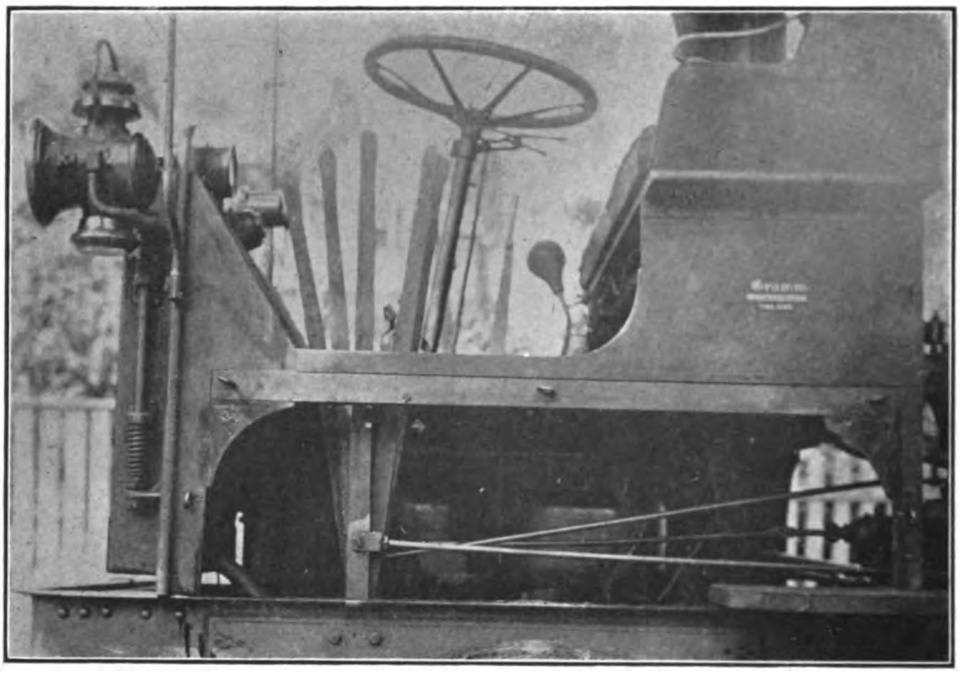
MOTOR EQUIPMENT IN MUNICIPAL SERVICE.

Experience of Pawtucket, R. I., Demonstrates That Substantial Economy and Undoubted Efficiency Result from the Use of the Mechanical Transport in the Street Department for the Suppression of Dust Nuisance.

EVERY municipality of proportions must afford to its citizens such service as its resources may justify. There is a wide variance as to requirements, but it is characteristic of American citizens to demand of a city or town whatever attention may appear desirable, it being assumed that the community as a whole ought to bear the expense of necessities or conveniences that in reality benefit a comparatively small number. Without question it is impossible to provide all that may be desired, but, aside from the matter of political expediency, there are certain classes of service that must be provided.

The municipal government must always regard its financial limitations, at least in theory, and the general experience has been that revenue is never adequate to provide all that is wanted by the citizens. There are certain divisions of the service that may with reason be restricted, temporarily, perhaps, while others must not only be constant but have a reasonable reserve to cope with such exigencies as may arise. While it is a fact that each citizen will unhesitatingly demand whatever may be considered a public or even a personal need, there is equal unwillingness to approve a rate of taxation that will yield sufficient revenue to meet all authorized expenses.

Gramm Truck Chassis Fitted with Tank and Pump for Street Oiling at Pawtucket, R. I., an Equipment That Has Supplanted 10 Water Tank Wagons.



The community government usually has another handicap in the fact that political expediency has caused the enactment of state or local laws limiting the hours of labor, and as a rule the work that is performed is materially less than what might be accomplished by a private corporation or firm for a given price. This is stated for no other reason than to emphasize the necessity of economizing the time of those employed by municipalities. That is to say, with the limitation of appropriations and of the hours of labor, and with the demands in excess of the departmental capacities and constantly increasing, there is extreme need of facilities that will either better the service at no additional expense or accomplish an actual saving.

There are some divisions in which time is the greatest factor and of these the most important is that affording protection against fire. The utility of the motor driven apparatus is such there can be no argument made against its use, and for the police department the automobile vehicle is so superior to other forms that it is not necessary to expatiate.

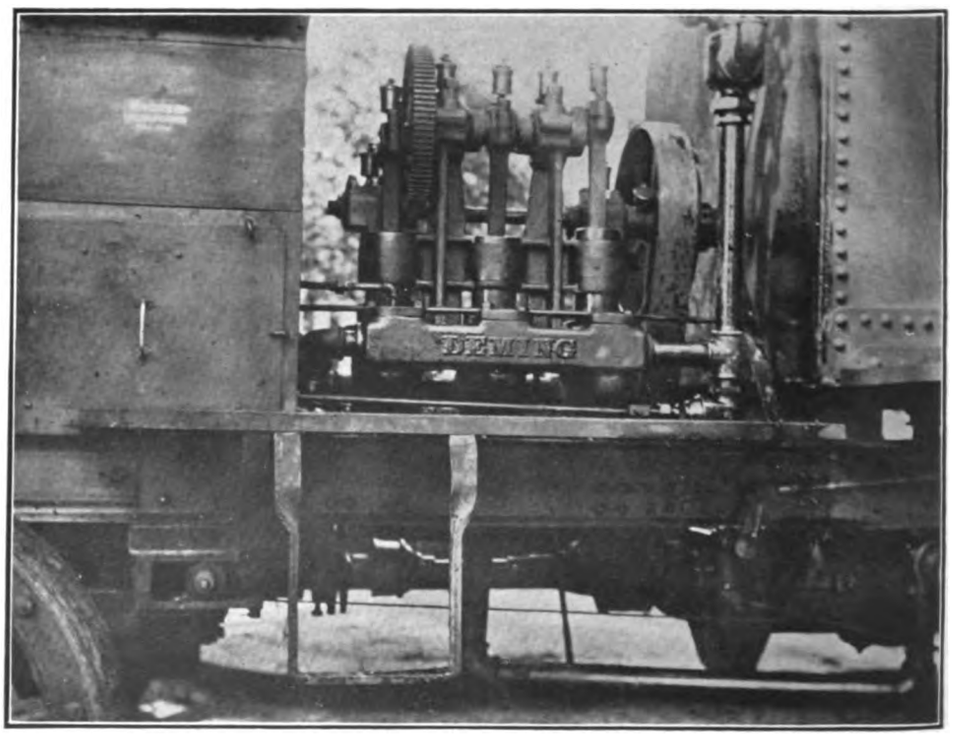
In either of the two departments specified, where time is one of the most important factors in obtaining satisfactory protection, there could be no issue made even were the expense greater. With the first the main requirement has been sufficient capacity to supplant the largest and heaviest apparatus, there being some doubt as to the reliability and endurance of the motors in the absence of specific experience. So far as the second is concerned there has been abundant evidence to establish the superiority of the automobile.

It is outside of these two divisions that the power conveyance has been least used. There is apparently a belief that it is not practical to give over the use of horses and carts because of the class of work that is performed in

Digitized by Google

Series of Hand Levers at the Left Side of the Driver's Seat by Which the Pumpage and the Distribution of the Oil Is Controlled.

street cleaning, street sprinkling, garbage collecting and other sanitary service, to say nothing of the varying construction such as street building, water works extension and maintenance, sewage system development and care, as well as other essential attention to city property.



In regarding the average municipal expenditure and the possibilities for economy it must not be believed that there are the same incentives to save money that would obtain with the business of the private enterprise. While it may be that some will say there should be no difference it is a fact that economizing is often not so much the object sought as to furnish employment to deserving voters who are willing to do the least that is possible for wage or salary paid to them. Where this is the condition obtaining it is useless to advocate economical methods.

In any event it is not practical to expect to better or improve a service by the changing of apparatus—that is, from animal to mechanical vehicles—to any great degree. The mere possession of the equipment is one thing. The essential is to make whatever change is necessary in the manner of use to secure the greatest practical use and consequent economy. This is not a radical recommendation. It follows that there must be rejection of the old to take advantage of the new, and if there is to be merely an increase of the service without additional expenditure the public is distinctly a gainer.

It will be admitted that it would be idle to use trucks or wagons as carts are or have been used for street cleaning, for example, because there would be the waste of time in loading the refuse and dust from the highways and the only saving would be in the time of cartage. If the haulage were a considerable distance the motor truck would have the advantage of speed and capacity, which might be sufficient to equalize the expense, but there would not be a large measure of saving. Besides, the truck would, with a driver, do the work of several men and carts, which would mean less work for somebody.

To illustrate the matter of method it may be pointed out that once the streets were leveled by use of the shovel and hoe. Later came the harrow on the dirt ways. Next the paving was swept by hand brooms and the dirt carried away by carts. The horse brooms were the next facility. It will be noted that each improvement has been made with a view of expediting the work and improving it so far as this may be done. In other words, the utilization of better tools or apparatus made it necessary to change the methods the vogue. Now, to take advantage of the increased capacity and superior mobility of the trucks it is imperative to abandon the old systems and adopt what will best serve. So long as there is no disposition to do this there can be no change for the better.

It is not to be assumed that any one system will be satisfactory to all communities and their requirements. It is far more reasonable to believe that those responsible for the administration of municipal departments can determine what will best serve them with the conditions obtaining. But it is a fact that it is far more economical to abandon equipment that may appear to be sufficient for all immediate requirements and adopt facilities that will extend and afford

Belt Driven Pump That Forces the Oil from the Tank Under a Pressure of 100 Pounds to the Square Inch and Affords Equal Distribution.

Oil Distributor Carried on a Frame Adjustable for Height and Masked to Prevent the Fluid Spraying Beyond a Determined Area.

a far more satisfactory service. As a business proposition it is far better to discard what is known to be insufficient and take up with that which will be better from every view point, although there may be an initial expense of considerable proportions.

To illustrate this in a manner that cannot be misunderstood the experience of the city of Pawtucket, R. I., has a practical value, because it demonstrates the possibilities of the adoption of methods that are reasonably progressive. Pawtucket has a large mileage of macadam and gravel streets, well constructed and well maintained. For years the highways had been watered from early in April to freezing weather in the autumn, with the usual results from such treatments. As the city increased in population the demand for dust suppression at least kept pace with the growth and it will be realized that this could not be and was not denied. As this article deals with the possibilities for improved methods and apparatus it is appropriate that there be some explanation of the changes made that resulted in the utilization of a truck for a work that required 19 watering carts, 19 pairs of horses and 19 drivers.

During the season of 1909 the city suppressed the dust by the use of water, using the equipment stated. The city owned the 19 water tank wagons and during the period of service a pair of horses for each cart and a driver were hired at a cost of $4.50 a day, this bringing the cost for each cart, exclusive of the interest on the investment, depreciation, water charges, insurance, etc., to $27.50 a week, or an aggregate of $522.50. As the city owns its own water works the water was supplied the department at the lowest charge—$60 a million gallons—which is probably a third less than the average price paid by cities. The work was systematically conducted, the city being divided into 19 districts in which one cart was worked each day rain did not fall. These districts were not equal as to size, they ranging from 37,100 square yards to 84,600 square yards of street area, and each driver was expected to so apply the water that the dust would be suppressed uniformly and to make as many applications as was possible. For the purpose of minimizing time in distributing the water standpipes were located as frequently as conditions justified. The expense of the standpipes was not included in the cost of watering.

The entire service was under the supervision of an inspector who was required to visit every section of the city and see to it that the drivers were doing the work required of them and to direct the men in a general way. Of course it was necessary the inspector have a horse and buggy to drive about. Some of the streets were sprinkled more frequently than others, the more generally travelled ways receiving the most attention.

The cost for watering 863,000 square yards of street during the year of 1909 was 1.4 cents a square yard, this including interest at four per cent. on the cost of the carts, water, new apparatus, repairs and supervision, but not the depreciation charge for the apparatus. It might be said that this item was taken care of by the repair account. The cost for the work varied in the different districts from .8 cent to 1.8 cents a square yard, which correctly represents the difference in the service. It might be well to direct attention to this particular condition because, with the use of water, the dust is suppressed only for a comparatively brief time, especially in hot weather, and the more insistent the demand for service there is no possibility of giving more than the normal distribution. In fact it may be said

Manner of Distributing the Oil, It Covering a Section of the Highway Seven Feet in Width.

Digitized by Google

The Emerson Dry Street Sweeping Machine, Which Has Been Experimented Extensively in New York, N. Y.

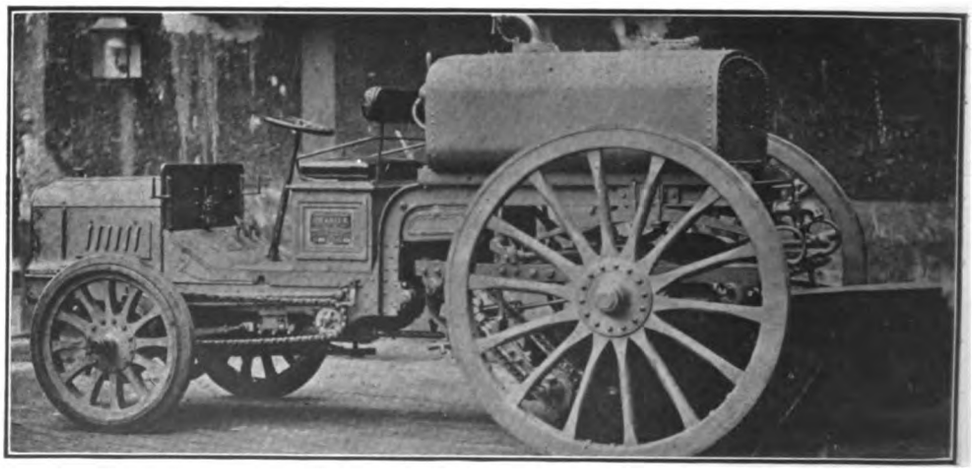
the experience is that when the weather is extremely hot the horses are not able to do as much as they would with a lower temperature.

There is always a considerable difference between the theoretical and the actual work accomplished because of the time lost by the men, and the people are the losers because they do not receive the service they expect. During periods when little rain falls there is greater need of water and that distributed is the more quickly dissipated. Water spread upon the streets has the effect of hastening deterioration, an excess being quite as bad as the lack of it. Under any circumstances the unproductive or empty travel of the watering carts was found to considerably exceed 50 per cent., despite the location of the standpipes.

The department of public works system, taking the maximum work of the carts by district, permitted the watering of from 2.76 to 6.58 miles daily, there being a total of 66.4 miles of highway in the districts served, allowing an average of 22 feet for street width and 13,000 square yards to a street mile. It will be understood that this required from two to four applications.

The use of oil was begun in 1910 and for this service, to cover the same districts, approximately 72 per cent. of the macadam and gravel streets, three watering carts were used. It was found that while the mileage was increased so that each cart served an average of 22 miles this was not satisfactory because of different character of distribution required. To illustrate, the carts were equipped with fan sprinklers from which the oil flowed by gravity. When filled the flow of oil was fairly even, but as the head was diminished the oil was spread to increased depth and over a lessened area, filling the depressions and creating pools from which the oil was thrown by passing vehicles, causing complaint from the owners of conveyances. Not only this the oil was often blown by high winds on to the walks and private property, resulting in extreme dissatisfaction, while it also was carried on the feet of pedestrians into buildings and houses.

So far as suppressing the dust the oil was decidedly superior to water. The oil was received in tank cars and taken by a spur track to the city yard where it was drawn from the tank and spread. The capacity of the tank wagons was 600 gallons each, and a 10,000-gallon tank containing approximately 17 loads could be emptied generally within the time allowed before demurrage was charged—four days. It should be understood that oil cannot be applied when the surface of the ground is wet and occasionally the work of distribution was delayed. It was decided that this was a satisfactory manner of handling the oil, although it would have been practical to have constructed a storage tank of large capacity and stored the oil to be drawn upon as desired. This would have prevented waits for shipments and the payment of demurrage, but the cost would have been considerable.



Receiving the oil in this manner developed another condition that was really serious. It was necessary to haul all the oil from the tank car to the different sections of the city where it was used, and careful study proved that fully 80 per cent. of the time of the carts distributing the oil was given over to hauling the oil and returning with the empty tank. In other words, four out of every five days were practically unproductive of labor. This condition could not be changed with the use of the carts and horses. But with this large factor of unproductiveness the cost of the oiling was not greater than of watering.

The experience was that it was best to make frequent applications of oil, the coats to be in the proportion of .1 gallon to the square yard, making at least two distributions and a week or more apart. This work necessitated a greater travel of the carts, while there was the same objection to them because of the uneven character of the distribution.

The city's watering equipment consisted of the 19 tank carts that cost $375 each. The interest on the investment was $270 figured at four per cent. The depreciation was not estimated and was met with a repair expenditure of $1387.90 in 1909. The net cost of the carts was $7125 plus the freight. With the use of water the 19 carts was not sufficient. With the use of oil three carts met all requirements. With the necessity of having a central location from which the oil might be distributed and utilizing the tank cars instead of a storage tank it was considered best to make an entire change of equipment.

When practical experience had demonstrated that oil was desirable from every point of view for the supression of dust the commissioner of public works was authorized to procure such apparatus as would in his judgment afford the greatest economy and efficiency. One purpose was to minimize the unproductive labor and the other was to better distribute the oil, so there would be no waste and eliminate any cause for complaint.

The department prepared plans of an apparatus that

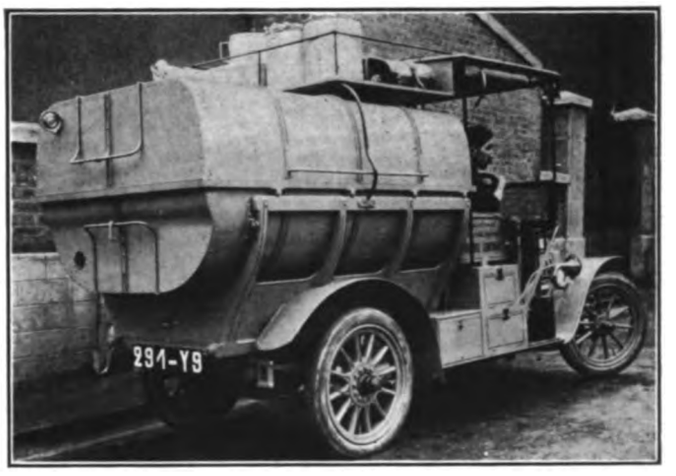
Combination Water Tank and Street Sweeping Motor Driven Apparatus That Has Been Adopted by a Number of European Cities.

Digitized by Google

was decided would answer every requirement and found that it was necessary to build it in part. First a three-ton Gramm truck was purchased and from this the body was removed. Then a sheet iron tank of 800 gallons capacity was built to specification and this was installed on the chassis. This size was believed to be best for all-round work and it was proposed to distribute the contents of an 8000-gallon tank in 10 loads. The tank was so constructed that it could be removed from the chassis in a comparatively short time.

Between the forward end of the tank and the driver's cab was located a Deming pump of the three-plunger type and the 16-inch driving pulley was belted to a seven-inch pulley fixed to the clutch shaft, forward of the transmission. The reason for this was that the pump might be driven at all times at engine speed. A standpipe was placed in the tank at the left forward corner with such clearance as to insure practically complete clearance of the tank. The connection with the standpipe and the pump was made so that there need be no pressure whatever in the tank, and the oil be forced by pump to a pressure of 100 pounds to the square inch through a line leading to the spray header suspended by tubes carried in guides at either side of the rear of the tank, these tubes being so constructed that they might be adjusted for height.

The pumpage is controlled by four levers at the left side of the driver. One of these operates a relief valve so as to diminish the flow of oil into the pump. A second permits the bypass of oil so that there may be a diminution of pressure at the header when climbing a hill slowly, for instance, and the engine is running faster than it would normally on a level. The third will shut off the oil supply to header near the pump, and the fourth will shut off the oil supply close to the header so that there will be no flow whatever, as when crossing a walk. It was believed that there might be some difficulty experienced when the speeds of the truck were changed, but it was found that this condition was not realized.



The capacity of the pump was such that a tank of oil could be distributed in about 40 minutes and as the flow was regulated at the header and directed downward onto the surface of the roadway the fluid would penetrate the surface very rapidly. With the tank wagons it was necessary during cold weather to heat the oil to a temperature of 150 degrees at the tank car by a coil of steam pipe to insure penetration, but this was entirely overcome by the use of the pressure distribution. That there might be no oil spray blown about by high winds the header was masked by a canvas covering that is but a few inches above the roadway.

Since the original construction several changes have been made in the apparatus, the pump pulley being reduced from 16 to 12 inches diameter, and the number of outlets increased from 13 to 26, this giving a more equal distribution. It has been found that it is best to change the distributing pressure than to vary the proportions of the outlets. The oil is pumped so long as the truck is moving or the engine is in operation. The control is very precise, as it is possible to oil a road to within an inch or two of a given point, and to begin or cease oiling whenever desired. This evenness of distribution is the same no matter what the quantity of oil in the tank. The tank truck is operated by two men, one driving and the other manipulating the levers by which the distribution of the oil is regulated.

When the truck was first placed in operation it was found necessary to do some experimenting for the crew to become familiar with it, but in a comparatively short time the men mastered it and were able to do exceedingly satisfactory work. In fact, one quality is that within a very few minutes after oil has been applied in light coats one may walk about on the road without any of the discomforts or annoyances that are experienced with other methods of oiling.

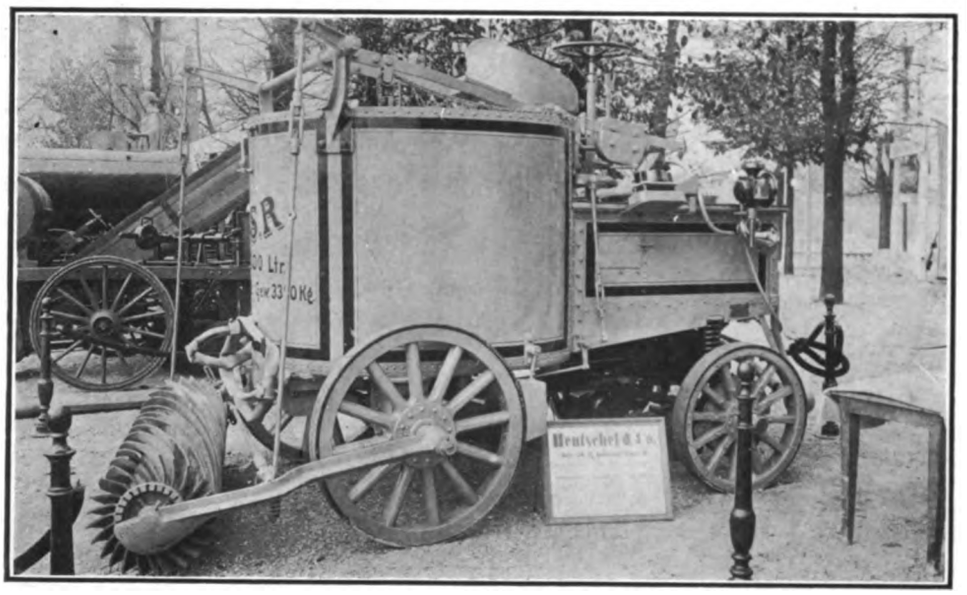
The equipment replaced the three watering carts used for oiling and not only does the work, but does it in every way more satisfactorily. It is not possible to keep the machine working all the time for as yet the needs of the city do not require it, but to indicate the capacity it may be said that often a tank car of 8000 gallons is emptied in a day, this meaning that 10 full loads are applied, though occasionally from 10 to 12 hours may be necessary for such work because of the distance of the distribution from the tank car. It is evident that should necessity require the truck could work on a 6000-gallon basis every day that the weather would permit the application of oil.

During 1911 the truck was driven approximately 10,000 miles, the greater part of this in street oiling, and a road area of 835,000 square yards was oiled at a cost of 1.17 cents a square yard, considering oil and labor. With the cost of repairs and supplies the cost was 1.25 cents a square

Truck Adapted for the Collection of Garbage by the Sanitary Departments of Several Cities of France.

yard. The saving shown is .15 cent a square yard, for the theoretical cost of watering was 1.40 cents, but this was somewhat increased because the actual work expected is never what is realized, there being more or less shirking by the men.

Besides the improvement of the distribution there is a distinct saving of 10.71 per cent., and an actual economy of probably 15 per cent., although the full capacity of the machine is not as yet realized. The city distributes between 250,000 and 300,000 gallons of oil annually, this being equivalent to about 350 tank loads, taking 275,000 as the quantity used. Estimating 6000 gallons as a day's distribution and there being 100 days of the year when oiling can be done, this would show an actual work capacity of 600,000 gallons, or more than double what is now required of the truck.



But besides the oiling the truck has proven itself especially serviceable in other ways. When the season closed the pump and tank were removed and the regular body installed and the truck was used by the water department during the entire winter, doing work that required eight hired horses and express wagons. It was loaded each morning with from 15 to 20 laborers and their tools and the men were carried to their work. They were brought back when the job they were on was completed, and not only saved their time, but the expense of the horses and wagons they had previously used. Besides this the truck hauled material and did no end of serviceable work. As a munici-

Digitized by Google

pal investment it was a decided success. When the winter's work was finished it was again equipped for street oiling and it is now in this service. It is expected that with the experience of the past year it will show even greater economy.

While this is, so far as is known, the only apparatus of the kind, motor trucks have been adapted to other kinds of municipal work. For instance, the Emerson dry sweeper is being carefully tried in New York City, this being a chassis fitted with a rotary engine driven brush at the back. The sweepings are carried up a chute over the top of the machine and into a compartment, a slight suction preventing the dust from becoming obnoxious.

A street sweeper that has been used with considerable success in a number of cities of continental Europe is a tank and rotary broom carried on two large steel tired wheels. From this tank water is distributed on the paving to lessen the dust and make certain the collection of the refuse. From the side of the street it is collected by wagons. The apparatus is driven by a Richard-Brasier motor and it is interesting in that the drive is by double side chains to the forward wheels, through a cone clutch and countershaft. On the steering knuckles are gear and pinion reductions. The broom drives separately.

Street Sweeper and Water Tank, Driven by a Motor, Very Generally Employed by the Leading Cities of Germany.

Another interesting apparatus utilized extensively in Germany is a motor driven tank carried on four steel shod wheels and carrying a rotary broom. This also sweeps the refuse into the side of the street for collection.

In France a motor truck is utilized by the sanitary department for the collection of garbage. The body is of metal, completely closed, and mounted on rollers on the deck of the chassis so that it may be withdrawn for dumping. The purpose is to facilitate the carriage of the garbage and to minimize the odor, while with the removal of the body the truck may be used for other work.

These are some of the practical uses for trucks in municipal service. They emphasize that with changed methods there is the best of reason for utilizing the superior qualities of these machines.

The Lippard-Stewart Motor Car Company, Buffalo, N. Y., maker of Lippard-Stewart trucks, has appointed the following agencies to handle its product: Whitney-Barney Company, Boston, for Massachusetts, New Hampshire and Vermont, and Taylor Motor Car Company, Pittsburg, Penn.

NEW CONTINENTAL MOTOR WAGON.

E. M. Anderson and Dr. J. G. Barnsdale of Superior, Wis., have incorporated the Continental Truck Manufacturing Company of that city, which has entered the commercial vehicle field with a Continental wagon of one to three tons capacity. Only one type of chassis will be constructed at present, to which will be fitted three standard bodies, one an open express, one a closed panel and the third a stake platform.

Perhaps the most conspicuous feature of the car is the extreme accessibility of the motor, which is a four-cylinder unit with bore of 4.125 inches and stroke of 5.25, located in front under the footboard. When this latter is removed the whole top and forward end of the engine are easily reached by the operator from the front between the wheels. The carburetor, magneto, force feed lubricator, pump, valve mechanism and piping are all exposed to view and readily accessible for work.

The motor is rated at 35 horsepower. The magneto is mounted on side of the crankcase. Cooling water is circulated by a gear pump through a radiator which forms a part of the dash and is out of the way of both accident and injury. An automatic governor is fitted so operator is effectually prevented from exceeding a predetermined speed.

The clutch is a cone member. The transmission affords four speeds, and the jackshaft carries the differential and sprockets, final drive being by chain. The frame is steel, double trussed, and is mounted on semi-elliptic springs in front and full platform members in the rear. These latter are not required to take the drive thrust, substantial radius rods being provided for this purpose. Brakes are internal expanding and external contracting.

Both axles are drop forgings of nickel steel, hammered into shape and then special heat treated without welds. The front member is of the I beam type three inches wide, while the rear is of solid steel, three by 3.25 inches. Wheels are larger in the rear than in front, the former being equipped with 40 by four-inch solid tires and the latter with 36 by 3.5 inches. The wheelbase is 120 inches and the tread 56.

DIAGONAL BLOCK TIRE.

The Diagonal Block Tire Company of Urbana, O., is producing a new tire, the Diagonal Block. As the name implies this tire is constructed on the block principle, each section or block being removable independently of the others. The outstanding feature is the shape of the section, which is rhomboid, so that it extends diagonally across the tire. This feature is claimed to give greater traction and at the same time the smooth running of the continuous tire. A booklet describing the product will be mailed on request.

The Luverne Automobile Manufacturing Company of Luverne, Neb., is to place shortly on the market a one-ton delivery car. The company has heretofore confined itself to pleasure car production.

NEWS OF THE COMMERCIAL VEHICLE INDUSTRY.

Buffalo's Electric Concern Makes Known Its Official Board—Several Trucks Ready for Their Initial Appearance—Other Interesting Items.

Announcement was made in these columns last month of the incorporation of the Buffalo Electric Vehicle Company, Buffalo, N. Y., with a capital of $1,000,000. At that time little was known about the concern, other than that it was to be a merger of five companies in that city for the manufacture of electric vehicles of all types. The personnel of the organization was made public in the election of officers April 22, and it is assured that the enterprise will not lack substantial and influential backing.

The officers are as follows: President, Samuel J. Dark, secretary of the Buffalo Dredging Company, secretary of the German-Bock Asphalt Company and director in the Commonwealth Trust Company; first vice president, A. A. Landon, president of the Clark Motor Company and superintendent of manufacture with the American Radiator Company; second vice president, W. A. Morgan, president of the Buffalo Taxi Company, director in the Buffalo Copper & Brass Rolling Mill and district manager for Swift & Co.; treasurer, Harry Yates, first vice president of the Union Furnace Company, treasurer of the Lafayette Hotel Company and vice president of the Commonwealth Trust Company; secretary, Alfred W. Thorn, president of the Thorn Cement Company and director in the Commonwealth Trust Company.

The directors are: President Dark, Vice Presidents Landon and Morgan, J. T. Steele and John W. Van Allen. Director Steele is an investment broker and Van Allen a prominent Buffalo attorney.

CHASE COMPANY DOUBLES CAPITAL.

The increasing demand for Chase trucks, made by the Chase Motor Truck Company, Syracuse, N. Y., has resulted not only in the decision to erect additional factory facilities, but at the last meeting of the stockholders the capital was increased from $150,000 to $300,000. The company reports good business conditions throughout the Middle West and Northwest, where the demand for its product has been increasing constantly since the first of the year.

DRIGGS-SEABURY TRUCKS COMING.

The Driggs-Seabury Ordnance Works, Sharon, Penn., has been engaged upon the construction of 20 motor trucks, which will soon be given their preliminary tests. It is understood that the concern contemplates entering the commercial vehicle field, building mechanical transports on a large scale. These models will be produced in capacities of three, four and seven tons, respectively.

ATLANTIC ELECTRIC TRUCK.

The list of electric commercial vehicles in the market is to be augmented in the near future by the addition of the Atlantic, to be made by the Atlantic Vehicle Company, North Newark, N. J. The line will include cars of one, two, 3.5 and five tons capacity. The designer is Arthur J. Slade, who has been connected with the production of electric automobiles for a number of years, in co-operation with others who are extremely well versed with the needs of the mechanical transport.

The officers of the company are: President, McKinley Boyle, until recently with the Continental Car Company of Louisville, Ky.; vice president and sales manager, Ralph Sanger, formerly with the machinery firm of Wanham, Sanger & Bates. Mr. Slade is chief engineer, although he will continue his private practise as a consulting engineer.

INTERESTED IN HART-KRAFT FACTORY.

According to a dispatch from York, Penn., a $200,000 corporation is in the process of formation for the purpose of taking over the factory of the Hart-Kraft Motor Company of that city. It is understood that the promoters have associated with them a practical man from the Mercedes factory in Germany; and that immediate steps will be taken to enlarge the present plant.

G. M. C. PAYS DIVIDEND.

The General Motors Company, of which the General Motors Truck Company, maker of G. M. C. gasoline and electric trucks, is a constituent, has declared a dividend of 4.5 per cent. on its preferred stock to stockholders of record April 15. The full dividend rate on this stock is seven per cent. a year, and the odd amount of the present payment is accounted for in the fact that the dividend date was pushed forward one month, because of interest payments which fell due April 1.

DIXON COMPANY'S ANNUAL MEETING.

At the recent annual meeting of the Joseph Dixon Crucible Company, Jersey City, N. J., maker of Dixon's graphite lubricants, 9304 shares of a total of 10,000 were represented, and the following officers and directors were re-elected: President, George T. Smith; vice president, W. H. Corbin; secretary, Harry Dailey; treasurer; George E. Long; assistant secretary and treasurer, J. H. Schermerhorn; directors, George T. Smith, William Murray, Edward L. Young, William H. Corbin, William G. Bumstead and Harry Dailey.

KELLY-RACINE TIRE DEMAND.

The Kelly-Racine Rubber Company, Racine, Wis., has increased its capital by $150,000. This move was made necessary by the volume of orders on hand, which could not be filled with the present facilities. The new capital will be used to enlarge the factory, so that the annual output, which has grown to $1,200,000 in the two years that the company has been manufacturing, will be considerably increased. George B. Wilson was recently elected president and general manager.

WOULD REORGANIZE COMMER INTERESTS.

A committee has been appointed by the creditors of Wyckoff, Church & Partridge, Inc., New York City, maker of Commer trucks in America under license from the English concern, looking toward a reorganization of the company. This committee consists of the following: H. M. Swetland, chairman; Chester Griswold, secretary; R. D. Moore, president of the Commercial Trust Company; A. Hauschild of the Polack Tyre Company; A. G. Bruckman, president of the Livingston Radiator Company, and A. B. Ralston, attorney.

LAMBERT TRACTORS IN LOS ANGELES.

Following the announcement that the Ford Motor Company of Detroit, maker of Ford pleasure and commercial lines, would erect a branch factory on the Pacific Coast, comes the information that the Buckeye Manufacturing Company of Anderson, Ind., will locate a plant in Los Angeles for the manufacture of Lambert farm tractors. It will be remembered that this latter concern has been engaged in the production of Lambert friction driven pleasure cars for several years, and recently began the manufacture of Lambert trucks, as well. The Lambert tractor is an entirely new proposition, although it has been experimented for some time at the Anderson factory. It is designed especially for use in orchards and in field work upon the farm.

It is understood that the Pacific Coast branch will be conducted as an entirely separate institution and that no pleasure cars or trucks will be constructed, at least for the present. J. W. Lambert, treasurer and general manager of the company, has been spending considerable time in the vicinity of Los Angeles, studying the market and the situation.

The Lambert tractor is a three-wheeled vehicle, the single wheel being located in front. The driver occupies an iron seat of the skeleton type placed at the extreme rear, steering being accomplished by an ordinary automobile hand wheel immediately in front of the operator. The column extends to a point near the centre of the vehicle and thence by the usual arrangement to the front wheel. The motor is located over the rear wheels, and the patented Lambert friction transmission is in front, and placed in a position exactly the reverse of that in the Lambert pleasure cars. It will be seen that the motor drives forward to the discs, which in turn drive backward to the traction wheels.

The rim of the front wheel is a broad band of steel with rubber in the centre, so designed that the rubber is utilized for travel over hard surfaces, and the steel comes into play the moment the wheel sinks in soft ground. The rear members also are shod with rubber, but in addition metal cleats are fitted for additional tractive effort when needed. The motor is rated at 40 horsepower, and is of the four-cylinder, four-cycle type. The entire design has been with a view of providing for an extremely low centre of gravity and the machine has been kept down to a height of 42 inches.

MONITOR SALES FORCE IN CHICAGO.

The general sales and publicity departments of the Monitor Automobile Works, Janesville, Wis., maker of Monitor commercial vehicles, have been removed from that city to Chicago, where headquarters have been established at 1421 Michigan avenue. J. E. Nordling, secretary and treasurer of the company, is in charge of the Chicago office, with F. W. Stewart acting as sales manager. President Westerlund remains in charge at the factory in Janesville.

CHANGES IN GOODYEAR FORCES.

The following changes have been made in the personnel of the selling force of the Goodyear Tire & Rubber Company, Akron, O., maker of Goodyear tires: George Bullock and Willard E. Parsons, San Francisco branch; G. R. Kreps and Frank R. Isaac, motor truck salesmen, Philadelphia; M. J. Dobler, city salesman, New York City; Woodson Reese, covering Missouri from Kansas City; H. B. Annable, Spokane, Wash.; H. C. Falkell, Cincinnati; C. G. Woodward, motor truck salesman, Memphis, Tenn.; F. B. Sullivan and Myron T. Sparks, motor truck salesmen, Boston, Mass.; E. C. Hied, Baltimore, Md.; Robert E. Campbell, St. Louis; E. F. Crawley, Jacksonville, Fla.; V. D. Lersch, Buffalo, N. Y.; J. H. Whetstone, Detroit; Glen Schrader, Dayton, O.; J. J. Kendall, Charlotte, N. C.; H. Q. Tenant, inspector adjusting department, Atlanta, Ga.; W. E. Dermody, New Orleans; G. T. Hancock, Newark, N. J.

NEW VICTOR OFFICERS.

At a recent special meeting of the Victor Motor Truck Company, Buffalo, N. Y., maker of Victor commercial vehicles and fire apparatus, Orson E. Yeager, president of the Buffalo Chamber of Commerce, was elected president of the concern. John A. Murphy was chosen vice president. H. B. Millard of Brooklyn, N. Y., was added to the directorate, with the two new officers.

F-S LIGHT DELIVERY CAR.

The F-S Motors Company has been organized in Milwaukee, Wis., for the purpose of producing a new light delivery car to be known as the F-S. It is understood that this is practically a constituent of the Filer & Stowell Company of that city, which already has a controlling interest in the Beaver Motor Company, the Petrel Motor Car Company and other important concerns in that vicinity.

DAY COMPANY LEASES FACTORY.

The Day Automobile Company, Detroit, maker of the Day Utility car, a convertible vehicle, has leased for five years the factory building recently erected at 25 East Milwaukee avenue in that city. It is of two stories, constructed of brick and will afford 20,000 square feet of floor space.

GENEVA WAGON ENTERS FIELD.

A concern which has held an enviable position in the horse vehicle industry for many years, but has now decided to enter the motor truck field, is the Geneva Wagon Company, Geneva, N. Y. Its product is to be known as the Geneva motor wagon, and while but one chassis will be provided, at least two standard types of body will be fitted. With the open body the capacity is rated at 2100 pounds and with the full panel type, 2300. The motor is a two-cylinder opposed unit, water-cooled, located under a short hood in front of the dash. The horsepower rating is 20, with a bore of 5.125 inches and a stroke of 4.5.

UNDERTAKERS PREFER MOTORS.

A situation which will prove of interest to those engaged in the manufacture of automobiles is disclosed in the action of the Hearse Builders' Association of America, at its recent annual meeting in Columbus, O. It developed that there was an increasing demand for the undertakers' wagons and hearses equipped with motors instead of being adapted for horses. The sentiment was so strong as to call for an expression of opinion among the members of the association.

TO MAKE KREBS TRUCK.

A new concern has been organized in Clyde, O., to be known as the Krebs Motor Truck Company, for the manufacture of Krebs commercial vehicles of 1500 pounds capacity. It is understood the motor will be a two-cylinder, two-cycle unit with bore of 4.5 inches and stroke of 5.5.

CONTINENTAL MOTOR'S NEW FACTORY.

What is claimed to be the largest factory building in the world devoted to the construction of motors for pleasure and commercial cars, has been erected by the Continental Motor Manufacturing Company, Detroit, on Jefferson avenue, near the plant of the Hudson Motor Car Company in that city. An accompanying illustration shows the outer shell of the building, as it was nearing completion and gives some idea of its extent. The cost of the structure was approximately $1,000,000, and it is expected to more than double the capacity of the company, which was held to be about 18,000 Continental motors annually.

In style and construction, the new building is similar to those of the Hudson company. Structural steel, reinforced concrete and steel window sashes make the factory as nearly fire proof as modern methods of construction will permit. To still further protect the property against danger from fire, an automatic sprinkler system has been installed throughout.

The total floor space is 240,000 square feet, the factory covering 12 acres of the plot of 30 which the company purchased recently. The main portion is two stories high and over 500 feet long, and was planned with the idea of securing plenty of light and air on all sides. The interior is fitted in the very best modern manner, and all machinery employed will be strictly up-to-date.

The Outer Shell of the Continental Motor Manufacturing Company's Plant in Detroit, Said to Be the Largest Institution of Its Kind in the World.

It is not the intention of the company to abandon its present plant at Muskegon, Mich., but the well known truck and pleasure car engines will be produced in both places. Quality will continue to be the governing policy of the concern, and it is anticipated that the Continental motor will continue to be the foundation stone upon which the success of many motor car and motor truck manufacturers are built.

WENONAH TRUCK FROM MICHIGAN.

A. B. Perkins, his three sons, and G. E. Porter have organized the Wenonah Motor Truck Company, which will be incorporated at Bay City, Mich. Vehicles of 1000 and 1500 pounds capacity will be constructed.

OREGON PRODUCT APPEARS.

The first vehicle produced by the Ewbank Power-Transmission & Motor Company, Portland, Ore., has made its appearance in the market, and plans are under way for the erection of a large factory in which trucks, fire apparatus and motor propelled railway equipment will be constructed. The basis of the new product is a gasoline-electric traction system designed by H. B. Ewbank, Jr., which involves the use of separate driving motors for each rear wheel, speed control being accomplished through the regulation of the engine. The officers of the company, which was organized in December, are: President, S. M. Mears; vice president, George W. Stapleton; treasurer, R. S. Howard; secretary, Dr. H. B. Ewbank; chief engineer, E. H. Ewbank, Jr.

MONEY FOR THREE-WHEELED VEHICLE.

The Wagenhals Motor Car Company, which has been engaged in exploiting a three-wheel light delivery car of that name, has secured sufficient capital in Detroit to warrant making plans for procuring a factory site. It is understood that production on a large scale will begin in the near future.

TRUCK FACTORY IN DAVENPORT.

According to a dispatch from Davenport, Ia., the business heretofore conducted under the name of the East Davenport Machine Shop is to be reorganized as a motor truck manufacturing concern. Two trial vehicles are now being constructed for local firms, and it is anticipated that these will prove sufficiently successful to warrant the production of vehicles of any size and model desired.

LANSDEN SECURES NEW FACTORY.

The Lansden Company, Newark, N. J., maker of Lansden electric trucks, of which Robert Schuttler Hotz of Chicago recently became president, has removed to a new plant which has been completed for it in that city. The building is 80 by 300 feet, and is expected to have a capacity of 1500 commercial vehicles a year.

LAUTH-JUERGENS COMPANY EXPANDS.

Plans are being prepared by the Allyn Engineering Company of Cincinnati, O., for a one-story brick and steel addition to the plant of the Lauth-Juergens Motor Car Company, Fremont, O., maker of Lauth-Juergens trucks. The building will be 60 by 200 feet and will provide ample accommodations for the present needs of the rapidly growing business of the concern.

EFFICIENCY IN WHOLESALE GROCERY SERVICE.

An Interesting Example of What May Be Accomplished with Mechanical Transport in Coping with a Situation in Which Horse Drawn Equipment Cannot Be Utilized Either with Profit or in a Practical Manner.

By C. A. French.

EFFICIENCY may be incapable of being reduced to dollars and cents, at least to the extent of placing the finger upon any one item and declaring beyond dispute that it has cost so much money to gain a certain result which is worth so much more money. Undoubtedly it would be possible to arrive at a decision as to whether one method of doing work were more economical than another, if the conditions under which this work were performed were exactly, or even approximately the same. In many lines of business it has been found that a motor truck, for instance, which it is best adapted is not sufficient to keep it busy all the time. In such cases it is necessary to provide additional employment, which might or might not be undertaken quite as advantageously by horses under ordinary circumstances. By this is meant that while the truck would not necessarily show an economy in the work at which it was placed in order to make use of what might be termed its spare time, its efficiency in the class of service for which it was best adapted would more than offset the difference, and whether or not it effected economy all of the time would prove im-

Allen Slade & Co.'s Knox Truck Starting Out from Fall River for New Bedford, After Its Plunge Through an Open Culvert.

could be utilized in hauling under identical conditions in which horses had been employed formerly or were still employed. Under such circumstances it should prove an easy matter to secure comparative costs, and wherever such have been obtained, the mechanical transport has given abundant indication of economy.

Until recently, many business men have been inclined to look upon the matter of economy with too little thought concerning efficiency. If a given truck can do a given work in less time than it would take a horse drawn vehicle to accomplish the same results, that is efficiency. It will indicate that if there be sufficient work to keep the truck busy it will replace a certain number of horses, and upon the number of horses it replaces depends the item of economy. It is not enough to show that a truck can do the work of sufficient horses to effect a definite saving. The two items of efficiency and economy can be combined only when the truck actually is doing the work of the horses it can replace.

But the haulage problem is by no means so easy of solution. There are times when it is possible to utilize a truck to advantage even when the work does not permit of its maximum efficiency. That is to say, the kind of work for material in considering this phase of the situation.

It may even be impossible to show definite economy in the work for which it has proved most efficient, for the reason that many commercial vehicles are being utilized in work for which it would be impractical to employ horses. In order to determine whether or not such utilization were economical it would be necessary to take into consideration other features of the business than the haulage problem. For instance, if it could be stated definitely that a certain amount of business was secured and retained through the use of a mechanical transport, the economy would depend upon the proportion of such business and the total cost of obtaining and holding it. Since other items enter into the consideration, and the nature of these is such as to vary with the individual concerns, it is a difficult matter to trace economy under such circumstances.

However, it will prove of interest to study an instance of this nature, reference being had to Allen Slade & Co., Fall River, Mass., a wholesale grocer employing 14 horses and two motor trucks. One of these latter is a two-ton Knox, made by the Knox Automobile Company, Springfield, Mass., which has been in service with this concern since July, 1909.

Digitized by Google

Allen Slade & Co., has its main offices in Fall River, with a branch establishment in New Bedford, 14 miles distant. The wharf is at Fall River, about a mile from the main store. Teams are employed in hauling goods from the wharf to the store, and in making deliveries to retail dealers in Fall River and vicinity. Other teams perform similar delivery service in New Bedford. The Knox truck is employed chiefly in transporting goods from Fall River to New Bedford, where it either delivers them to the branch house or to retail dealers as occasion demands. When not thus utilized, it makes deliveries in Fall River and brings goods from the wharf.

It readily will be seen that if it were employed continuously in one line of work or the other, it would be possible to compare its service with that of horse drawn equipment. Under the circumstances, however, this is entirely out of the question, and to quote the transportation manager, William Buffington: "It does not interest us particularly what this truck costs, since it does work it would be impossible to undertake with horses."

To explain this statement, it is necessary to offer a comparison. An attempt was made to serve the New Bedford route with a four-horse team. In order to make the trip at all, it was found necessary to load the wagon and start from Fall River at 9 in the morning. This outfit delivered the goods at the New Bedford branch and returned to Fall River at 7 in the evening. With the truck it is possible to begin loading at 11 in the morning, visit New Bedford and return at 3:30 in the afternoon.

When Mr. Buffington uses the word "impossible" it is obvious that he means something more than this explanation would indicate. It must be remembered that a stock of goods is kept on hand at the New Bedford branch, and when it is necessary for the truck to make delivery thereto, it is because something is needed. There was a time when a retail dealer was forced to give an order for goods and wait until the steam railroad could deliver the freight. Nowadays, no such delay is tolerated. The wholesaler who cannot deliver the goods when wanted must give way to the concern which can and will. As a result, the retailer orders when he needs the goods, and he expects delivery as soon thereafter as modern methods will permit.

Therefore, when the retail dealer goes over his stock in the morning and finds he must have certain goods, he calls up the wholesale house by telephone. The firm which can fill this order in time for the afternoon delivery from the retail store, gets and retains his business, other things being equal. If the retailer is forced to wait until late in the afternoon for his goods, it may mean the possible disappointment of one of his best customers, and he will no more wait for horse delivery than he will depend upon the railroad, when either or both can be avoided.

But even if it were "possible" to utilize horses to advantage, it would still be impractical, for the reason that it would not be possible to do the work with four horses. By this is meant it would require the maintenance of reserve animals in order to continue such deliveries. Allen Slade & Co., keeps a reserve of three or four horses, in order to have the actual services of 10 or 11. This is practically a percentage of from 30 to 40, which is by no means excessive, when it is known that some concerns operating in the larger cities carry a reserve as high as 70 per cent. It would not be difficult to show an economy in the use of the Knox truck if its work were confined to the New Bedford delivery.

There is still another way of looking at the matter. If it were not for the fact that it is possible to make quick delivery over the road with the Knox, it would be necessary to carry a very much larger stock at the New Bedford branch, which not only would mean a greater amount of capital tied up in goods which might not be needed, but would necessitate the employment of additional horses in that city. At present there are three teams engaged in handling the deliveries from the New Bedford branch to dealers, and the Knox helps reduce their work by making some deliveries direct. Mr. Buffington estimates it would take at least five teams, were it not possible to utilize the truck in this manner.

The New Bedford trips are not made daily, and it will be seen that the truck is not employed all day long when trips are made. It makes deliveries around Fall River, and hauls freight from the wharf. Something must be said concerning this latter work. Here the truck can and does make 20 trips a day between the wharf and the store. The horse wagons make five on an average, and six in an emergency. It depends somewhat upon the nature of the freight. Mr. Buffington says that in carrying barrel sugar the Knox will replace four two-horse teams, with bag sugar three, and with canned goods two. If some satisfactory method of quick loading and unloading could be devised, he thinks he could safely count on doing the work of four two-horse teams right along. It is significant that no more horses are being bought by Allen Slade & Co., and that when new equipment is needed, motor trucks will be purchased.

Knox Owned by Allen Slade & Co., on Parade, Loaded with Two Tons of Coffee.

Concerning the truck itself: It was designed and delivered as a two-ton vehicle. After it had been in service a few months, the company found that two tons was not all the freight it desired to transport with it, and it was decided to have the rear axle replaced by three-ton construction. Mr. Buffington says that it has carried three tons on a few occasions only, and that for the most part it has been hauling loads averaging 2.5 tons. The present construction is held to be ample for this work, with plenty of reserve for an emergency.

Most of repairs have been such as applied to what might be termed the wagon portion of the truck. Very little has

Digitized by Google

been expended on the motor and transmission. Four new springs have been purchased and new brake shoes have been secured. The vehicle was completely overhauled at the factory of the Knox Automobile Company in the spring of 1910. It was not given a thorough overhaul at any one time in 1911, although pretty nearly the whole machine was gone over by the driver at one time or another. A few weeks ago, during a heavy rain storm, on a return trip from New Bedford, it went through a culvert which had been washed away. When a relief driver was sent out to bring it home, only the rear wheels were visible above the road surface. This gave abundant opportunity for a thorough overhaul, and as may well be imagined several parts had to be replaced with new ones. This hardly can be considered as the fault of the truck, and it must be added that the work of repairs was made in this instance, as has always been true of any necessary adjustments or replacements since it was purchased, under the shed at the store near the loading platform.

The company maintains a small repair shop in the rear of the store. Here the operator does what work is necessary, and such machine work as he requires is done under his supervision at one of the nearby shops. The truck is garaged under the shed, and although this has been an exceedingly hard winter, there never has been any trouble about starting in the morning. Mr. Buffington says the car is in as good condition today as when it left the factory, and better, as far as the work for which it is required is concerned. An accompanying illustration shows it loaded ready for the New Bedford trip. This was taken one day this last month, and shows the machine after its experience in dropping through the open culvert.

Tires have offered a greater problem than any other part of the vehicle. Still, this item does not appear to have proven at all unsatisfactory. Hartford solid tires were employed until very recently, and the present equipment is the new United States demountable. All tires have been furnished on a guarantee of 8000 miles, and twice this mileage was obtained on the front wheels. The average for the rear wheels has been from 5000 to 6000 miles. The tire maker always has made satisfactory adjustment, and the tire expense figures out at 3.5 cents a mile for the two years and nine months. Fall River has the reputation among tire salesmen of being exceptionally hard on wheel equipment, much of the pavement being Belgian block. The experience of Allen Slade & Co. appears to have been quite satisfactory for all concerned.

In the matter of gasoline, no exact record has been kept, except at rare intervals, and then only for a week at a time. It is estimated that the truck travels an average of 30 miles a day. It will be seen that the New Bedford trip would make at least 28, not counting any deliveries which may be made to retail stores there. Twenty round trips from the wharf to the store would give 40. Thirty miles appears to be a conservative estimate. Such records as have been kept indicate a mileage of about seven to the gallon.

The operator is particular about the oiling system. Once in two or three weeks he draws off all the oil and puts in a new supply. This old lubricant is thrown away, although it might be considered possible to strain it and use it again. It is believed that a safe estimate of the oil used is an average of a pint a day.

Mr. Buffington has a somewhat unusual method of figuring depreciation. At the end of the first year he wrote off $1800. The truck cost $3800. He says he can maintain the vehicle at the remaining $2000. If he were to consider depreciation he would figure 10 per cent. after that first year. He prefers to figure repairs in lieu of depreciation and expend such a portion of the $200, which would be 10 per cent. on $2000, in bringing the car to that figure. He has no means of knowing whether he expends the whole $200, although of course he expects the repair bill to exceed that figure this year on account of the accident. Included in the repair and overhaul expense is an annual item of $35 for painting.

Taking these figures as a basis, it will be possible to obtain a satisfactory estimate of what the truck has cost Allen Slade & Co., during two years and nine months. Granting that the average daily mileage was 30, counting 300 working days in a year, the total distance covered has been 24,500. At seven miles to the gallon for gasoline, this would give 350 gallons. A pint of oil a day for 825 working days is 106 gallons. Depreciation is figured Mr. Buffington's way, and interest is based on the original cost of the truck. The table follows:

Gasoline @ 11 cents a gallon	$ 385.00
Oil @ 50 cents a gallon	53.00
Tires @ 3.5 cents a mile	857.50
Depreciation, first year	1800.00
Repairs in lieu of depreciation	350.00
Interest, 6% on $3800	627.00
Total	4072.50

This gives an annual expense of about $1480. It should not be understood that this is anything other than an estimate, based upon the figures as given by Mr. Buffington. While Allen Slade & Co. does not keep an exact record of its horse costs, it is claimed by others in Fall River that it costs about $5 a week to utilize horses. Evidently, this does not include depreciation or the expense of maintaining wagons and harnesses. In other cities, the size of Fall River, the cost of horse drawn equipment figures out at between $500 and $600 a year. The number of animals this Knox truck could replace at various lines of work is indicated herein. Those who desire may make their own estimate as to the economy effected.

As was stated earlier in this discussion, the principal point at issue is the matter of efficiency. In this respect, there is much to be said for this Knox truck. Leaving out of consideration the 10 days necessary to put it in condition after the accident in the culvert, it has lost two days' time since Jan. 1. This is about the average maintained for the year, 1911. In 1910 it was out of service for some time while at the Knox factory for an overhaul, and its greatest loss in this respect was occasioned during the first year of its life. Mr. Buffington holds that the first year is the worst of the lot. After the truck has had opportunity to accustom itself to the work expected of it, he believes there is less liability of damage and less necessity for lost time.

TIME AN IMPORTANT FACTOR.

The Peerless Motor Car Company, of Cleveland, O., maker of Peerless pleasure and commercial lines, is calling attention to the fact that to realize the full efficiency of the motor truck, loading time should be reduced to a minimum. This is seemingly a simple proposition, but too often neglected, many a driver running his vehicle at break-neck speed to the depot or factory, only to waste valuable minutes in loading or unloading when he arrives there. The efficiency of many a truck will be much raised if attention is given to the methods of loading and unloading with the idea of keeping the car moving as much as possible.

FIRE WAGON FOR BEVERLY.

Beverly, Mass., is planning to follow the lead of Salem, which recently purchased a motor chemical wagon for $5800. Chief Arnold of the Beverly fire department, has inspected the Salem apparatus, and is much pleased with the machine, which has a speed of 60 miles an hour and carries large chemical tanks and considerable equipment.

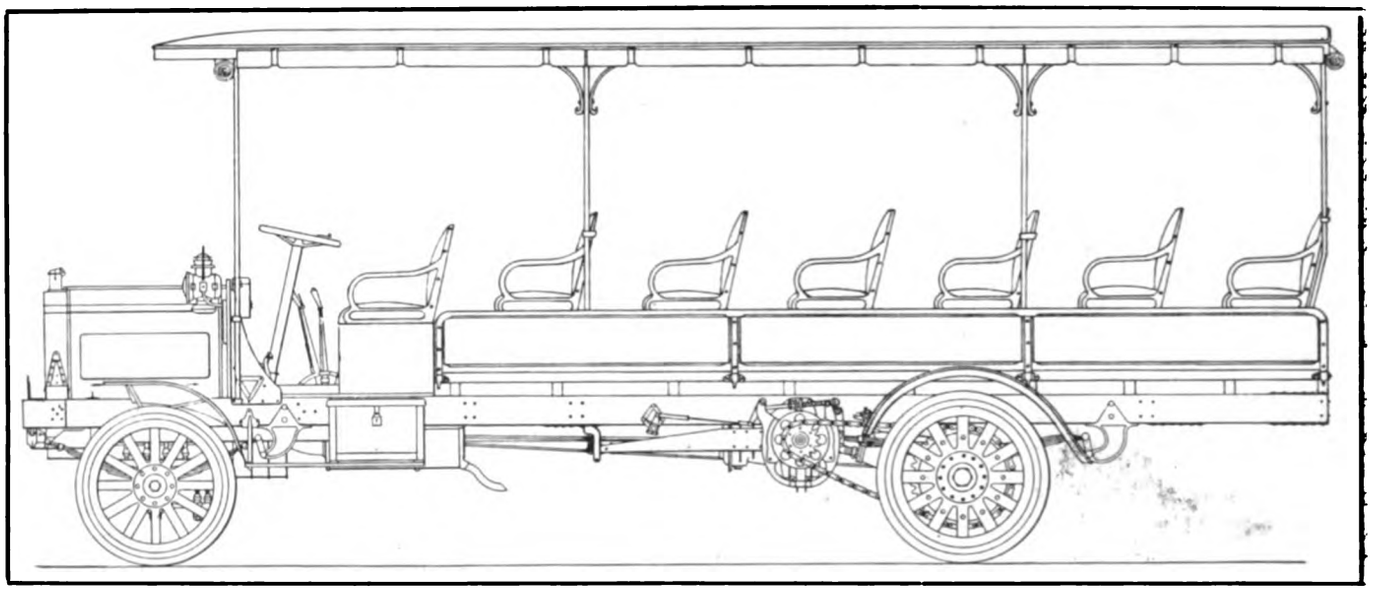
COMBINATION PASSENGER AND FREIGHT BODY.

BODY design and construction is only just beginning to receive the attention from motor truck manufacturers which the importance of the subject demands. Many of these concerns will continue to devote their efforts to the production of chassis which shall meet the requirements of the severe uses to which they will be put, leaving this matter of body design to others, who have been devoting their fore the mechanical conveyance came into vogue. This apfore the mechanical conveyance came into vogue. This applies to all types of vehicles.

Presented herewith is a combination freight and passenger body designed and constructed by the Motor Truck Body Company, Detroit, a concern which is eminently well fitted to take up this problem, its members having had extensive experience covering several years. The body is of sufficiently heavy construction to permit of carrying a three-ton freight load, should the purchaser desire to remove the seats disposed behind the driver and utilize it for that purpose. As shown it will accommodate 32 passengers in a convenient and comfortable manner.



The boards along the sides are folded up for the convenient loading of passengers, and when in an upright position they make a very good signboard for sight seeing advertising. In addition to these the hinged tail gate is particularly advantageous for the easy loading of freight from the rear and holding it in place when loaded.

To return to the seats. These are of the same order as those employed with the standard street car construction, with regular spring cushions and padded back, making for decided comfort. The front seat is hinged, giving the driver easy access to the gasoline tank.

The top is of light slat and canvas construction, supported by steel standards with suitable bracing, which fit into sockets on the floor, making for easy removal. Curtains are furnished to enclose the body completely, a special feature which will be more apparent in stormy weather. Celluloid lights of sufficient size to light the interior are provided in each.

The particular advantage of this assembly and one which is expected to make its appeal to those engaged in catering to summer visitors, is found in the fact that it can be converted at once from a passenger or sight seeing 'bus into a freight carrier. Thus, it will be seen that it might be utilized in the morning for conveying the guests to the hotel, and on the next trip to bring their baggage, while in the afternoon it could be employed in taking tourists to points of interest. After the vacation season is over, it can be transformed permanently into a general utility truck for all sorts of light and heavy work.

It hardly need be mentioned that the appointments throughout are of the very best material. Nothing in the way of appearance has been sacrificed to meet the demands of utility. The company has found this type of body to be greatly in demand, not alone because of its exceptional adaptability but because of its value as a means of drawing patronage through its excellent provisions for comfort and attractiveness.

Combined Passenger and Freight Body Designed to Seat 32 Persons and Constructed by the Motor Truck Body Company, Detroit.

NEW McINTYRE AGENCIES.

The W. H. McIntyre Company of Auburn, Ind., has closed a number of agency contracts since the first of the year. This make of truck will be well represented in all parts of the country, as may be seen by the list which follows:

McIntyre Commercial Car Company, Hartford, Conn.; Mechaley Auto Company, Stamford, Conn.; Shinkle, Richardson & Co., Huntington, Ind.; Fox Bros., LaCrosse, Wis.; McIntyre Auto Sales Company, Webster, N. Y.; Imperial Motor Car Company, Nashville, Tenn.; C. E. Swanson, Chicago, Ill.; Syracuse-McIntyre Company, Syracuse, N. Y.; Werick Bros. Motor Car Company, Buffalo, N. Y.; George R. Beeson, Connersville, Ind.; Kingman Plow Company, St. Louis, Mo.; Bradley, Merriam & Smith, Council Bluffs, Ia.; E. Wiley Hill, Butte, Mont.; McKee & Scott, Fresno and Bakersfield, Cal.; McIntyre Auto Sales Company, Albany, N. Y.; Standard Motor Truck Company, Boston, Mass.; D. F. Head, Ithaca, N. Y.; H. H. Maurer, New Berlin, Penn.; Lovegrove & Co., Philadelphia, Penn.; F. B. Austin, Little Falls, N. Y.; Banta Bros., Peoria, Ill.; J. J. Aker, Schenectary, N. Y.; Owen M. Smith, South Whitley, Ind.; F. A. Burmeister, Memphis, Tenn.; Hartford City Auto Company, Hartford City, Ind.; J. August Schmidt, Gloversville, N. Y.

NEW YORK'S ANNUAL DEMONSTRATION.

Motor Truck Club's Second Parade Indicates Business Concerns in the Metropolis Have Increased Their Motor Equipment at Least 100 Per Cent.

A DEMONSTRATION which will have a decided practical value in furthering the interests of the commercial vehicle industry was held in the second annual parade of the Motor Truck Club in New York City, April 13. Not only were there something over 400 machines in line, as compared with the 234 of 1911, indicating a gain of at least 100 per cent. in the number of such vehicles utilized by the business interests in the metropolis, but the plans this year contemplated something more than a pageant. Nearly all of the entries were made by owners, and in many instances the cars were loaded with actual deliveries which were made up-town after the parade was disbanded at 125th street.

The formation was at Battery Park, and the parade moved directly up Broadway, save for a short detour through 22nd street, Fourth avenue, 27th street, Fifth avenue and 48th street, this being for the purpose of visiting the business section of the city, at a time when the demonstration of the city's progress in modern transportation equipment would prove most beneficial to business interests. Preceding the entrants was a Fifth avenue motor omnibus, on top of which was carried the band, and supplementary trumpeters were disposed at intervals throughout the formation.

Formation of New York's Second Annual Parade of Commercial Vehicles at Battery Park Ready for the Start.

Herewith is presented the official entry list, from which it will be seen that numerous trucks were in line which appeared at the last moment and were assigned places without their names appearing on the list. By actual count at the reviewing point, Broadway and 100th street, there were 420 vehicles represented, although it is estimated that nearer 500 took part at one time or another. Some idea of the extent of the parade may be gained from the fact that it took 50 minutes for it to pass a given point.

Practically every type of car was represented, from the small electric crane trucks of the General Vehicle Company to the 10-ton Hewitts, made by the International Motor Company, and not forgetting to mention the two three-wheeled Martin tractors of the Knox Automobile Company. There were three of the G. V. electric cranes, and these attracted much favorable comment throughout the entire journey.

The plan of adopting a one-way route undoubtedly had much to do with bringing out the entries. In other respects it had its special advantages over the scheme of last year, when the trucks made a circuit of the upper end of the city. Perfect order was maintained at the start and the machines formed an unbroken procession in three divisions, but because of the excessive traffic in the business section, the parade was more or less scattered at times, a number of gaps showing in the line.

The largest number of cars of any one make in line was the G. V., made by the General Vehicle Company, Long Island City, N. Y., with 49, of which but five were entered by the company itself. Second place went to the Autocar Company, Ardmore, Penn., with 46, but in this instance the Autocar Sales Company was represented by 25. The International Motor Company, New York City, had no less than 57, these being divided between 25 Macks, 13 Saurers and nine Hewitts. It should be remembered that these figures are based upon the official entry list and might possibly need revision were it possible to secure a full count of those in line.

Other concerns represented, with the number of cars for each, according to this same source of information, were: United States Motor Company, (Alden Sampson Manufacturing Company) New York City, Sampson, 38; General Motors Truck Company, Detroit, G. M. C., 31; Knox Automobile Company, Springfield, Mass., Knox and Martin tractor, 16; American Locomotive Company, New York City, Alco, 14; Knickerbocker Motor Truck Manufacturing Company, New York City, Knickerbocker, 10; Wyckoff, Church & Partridge, Inc., New York City, Commer, 10; Packard Motor Car Company, Detroit, Packard, 10; Pierce-Arrow Motor Car Company, Buffalo, Pierce-Ar-

AMERICAN EXPRESS COMPANY'S CARS.

Five years ago the American Express Company, New York City, did not have a single motor truck, taking care of its hauling by horse drawn vehicles. About 1600 horses were used, these being housed in 25 stables. In 1907 it was decided to try out a number of motors and an electric was placed in service, followed the next year by a gasoline vehicle, and in 1909 by 15 three-ton gas trucks and four electrics. Careful records were kept of the two types of cars, and these showed that the gasoline truck was superior for the long hauls between the depots and delivery stations, while the sphere of the electric was found to lie in the shorter delivery routes.

The result of the experiment by the American Express Company was that last year 20 gasoline cars and 75 electrics were ordered, making a fleet of 40 gasoline cars and 80 electrics. In addition to this large motor equipment, about 1300 horses are still retained by the company. The business handled by this equipment can be estimated readily when it is known that the average figures show 60,000 packages are carried daily.

The company plans to do away with horses to a large extent, and preparations are being made to add 100 machines to the present equipment of 120. The company's building on 42nd street is to be remodelled into a modern electric vehicle garage. The second floor will be fitted with charging accommodations for 100 machines, and will be reached by means of four six-ton electric elevators. Of course, the charging will be in the hands of an expert, and one of the features of the system will be an annunciator which will signal when a truck's battery is charged, notifying the operator to throw the switch.

The chauffeurs for the motors were taken from the ranks of the horse drivers, who found no difficulty in handling electrics. The gasoline cars, however, were given only to those who displayed some mechanical ability. All these men knew the geography of the city and were familiar with the work, so that no time was lost in making use of the motor equipment as fast as it was acquired.

G. V. ELECTRIC TRUCKS AND WAGONS.

THE possibilities of the electric motor driven vehicle in highway transportation are not often understood. Those considering haulage subjects are inclined to eliminate the electrics simply through lack of knowledge of the service that may be obtained with them. Those who are informed understand that there is a definite use or uses for such transports, and long experience has well established the efficiency of the electric wagon. Those who adopt them do not experiment. There is no uncertainty from any point of view.

Perhaps one of the most misleading and erroneous suppositions is that horsepower rating of the electric wagon is comparable with other forms of power generators. That is, that the electric motor has not capacity or productiveness because it is not rated as are other engines and motors. It might be well to emphasize that the motor of the electric service wagon is capable of sustaining a 300 per cent. overload (developing practically four times its rated power) while the average motor or engine will only produce its rating at or very near its maximum production. With this fact in mind the electric vehicle appears in an entirely different light.

The General Vehicle Company's Standard Chassis for a Light Delivery Wagon.

Another cause for confusion is the assumption that capacity is measured by the mileage that may be made. The mile-an-hour speed of the conveyance is multiplied by the 10 hours regarded as a working day, and the total appears to be much more than can be made with an electric, when as a matter of fact, the actual daily travel may be not more than 40 miles for a delivery wagon and 30 miles for a truck.

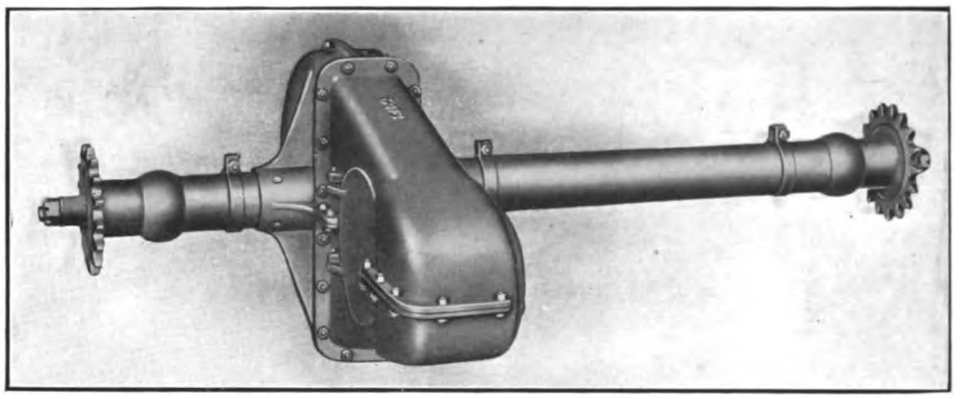
The remainder of the time is given over to loading, unloading, waits, stops in traffic and other delays. Comparing the work actually accomplished, however, it will be found to be practically twice that possible with horses, to say nothing of the increased load capacity of the electric machine.

The electric wagon or truck is particularly adapted for urban service. It has many qualities that are absolutely necessary for economy of transportation. It can be utilized in congested traffic with a certainty that is surprising and it has a flexibility of movement that minimizes wear of working parts and tires. The motor has elasticity the equal of the steam engine and there are no stresses that are destructive of the chassis.

The endurance of the electric wagon is surprising. It is far greater than the animal vehicle and the animal in service. It is the experience that the average horse will serve from three to five years if worked on the paved streets of a city. A first class wagon will endure perhaps five years. The General Vehicle Company, Long Island City, N. Y., after an experience covering a dozen years, makes the positive statement that the machines it builds can be depreciated at the rate of 10 per cent. a year, an assurance that has a liberal margin. As a matter of fact the first vehicles that this company built are now in daily service in New York City, after nearly 12 years' constant work.

Great Progress Made.

It is certain enough that great progress has been made in vehicle construction during the period mentioned. When it is realized that the first wagons were more or less experimental, and that each succeeding design has been improved, it will be admitted that results with the latest types ought to be even more satisfactory and basing expectations on actual knowledge, the percentage of depreciation may be somewhat lessened.



There is no question that this small depreciation is a very potent factor in estimating cost of service. Taking the figure set by the General Vehicle Company as a standard it will be understood that there is a difference of from 10 to 15 per cent. annually as compared with other types of machines. Assuming that all other conditions were equal this would be sufficient justification for any business man to decide that the electric truck was desirable.

There is no stronger argument than this when economy is considered, and yet the cost of maintenance is decidedly small. This, of course, implies that there will be regular and systematic care. This must be given with animals and other forms of vehicles, and it is assumed that attention will be uniform.

Simplicity of Operation.

Those who are asked to consider electric machines look upon them as being complicated and mysterious. As a matter of fact there is nothing more simple than this form of chassis, for there is but little aside from the motor, battery, controller, and the frame and wheels. Instead of puzzling problems the attention necessary with the motor and the battery can be given by any intelligent person. It is not essential to have a special training to care for either.

Digitized by Google

The Countershaft Housing and the Assembly, with the Case That Houses the Drive Pinion and Gear and the Morse Silent Chain.

Mechanical knowledge is not imperative, though desirable, but common sense will amply qualify one to give the needed attention. This statement is not intended to belittle mechanical skill or capacity, but to emphasize how absolutely simple the electric truck or wagon really is.

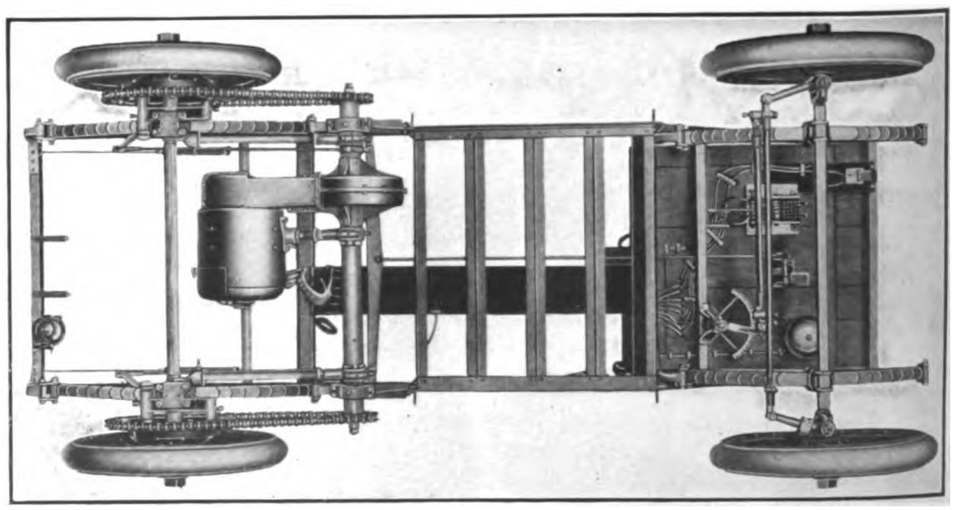
It may be well to point out that companies producing power for public service exist in practically all communities of proportions, very often in connection with lighting. The power may be created by steam or water, but it is distributed as electrical energy and is utilized in motors. In the best equipped shops and works it is the custom, because of the undoubted economy, to have individual motors for each machine. The value of such installations has been established beyond question.

No business man will maintain that the electric motor is not dependable. Hundreds of thousands of them are in use each day, from the tiny equipment that will operate a sewing machine to the motor that energizes an entire plant. These motors are operated day after day and month after month, with surprisingly little attention. Cleanliness and sufficient lubrication are the two essentials. There is a very small loss of efficiency through wear. There is no other type of energizer that will show so slight a loss of power, and the electric motor has the quality of delivering its capacity instantly and for as long a period as is necessary.

The manufacturer who has modern power equipment for his mill, shop or works will indorse the electric motor. He will accept a statement for its efficiency as final, because he knows from experience.

Practical Service at Minimum Expense.

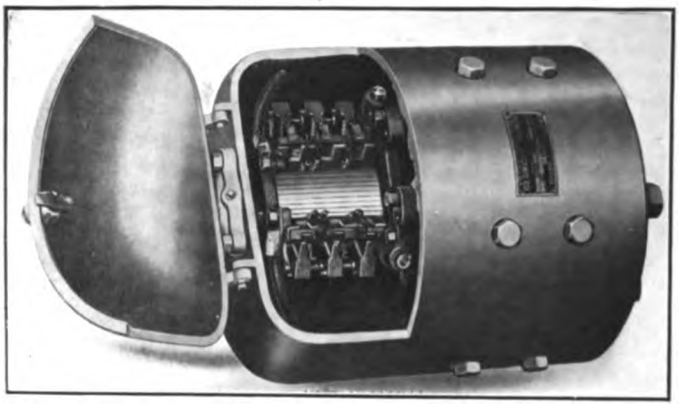
Turning to the vehicle itself it is best to deal with facts that cannot be controverted. There is no better authority in America, perhaps not in the world, than the General Vehicle Company, which has produced machines for more than 11 years—since it was established Jan. 1, 1901. It is well to state that no other types have ever been built and as the company was created as a business enterprise, by men accustomed to large undertakings and desirous of attaining a large measure of success, nothing was sacrificed to sentiment. The wagons were first of all designed with the object of securing extreme endurance. Capacity was an equally potent factor, and this included load carrying and speed and mileage. But with these the matter of economy was carefully considered. The economic aspect of the electric has been studied to obtain the largest practical service at the minimum expense.



It is an undisputed fact that during the past decade remarkable progress has been made in the perfection of the electric motor. The very general use of electricity for lighting and power has reduced the cost of energy from 66 to 75 per cent. With the improvement of the motor and the reduction in price of current it is not unreasonable to assume that the actual cost of driving an electric vehicle a mile today is about 80 per cent. less than it was 10 years ago. Thus it will be seen that the present economy of the electric is due to two entirely different influences, which, while in every way separate, are thoroughly in harmony.

It is not too much to expect that there will be equal improvement of the machines and a still further reduction of the price of current. The increase of battery capacity is another equally certain result. But what has been and will be stated relative to the electric wagon is not based on speculation. It is merely a recital of facts of record.

The General Vehicle Company is a pioneer in the electric vehicle industry. Less than 100 customers own 1000 wagons and trucks it has built. Twenty customers own an average of 30.6 vehicles each, or a total of 612. One industry alone has invested more than $1,000,000 in its machines. It is pointed out that of the 1911 business of the company 69 per cent. was in the form of reorders from customers operating vehicles made by it, a remarkable commentary on the character of the service obtained and the nature of the attention given to the patrons.



Design and Construction.

Obviously the satisfaction obtaining with an electric vehicle in service is dependent upon the design and construction, and the three factors are simplicity, accessibility and standardization. Without standardization the vehicles must be built to specification, a class of production that is necessarily more expensive and entails the maintenance of more or less factory equipment of uncertain productiveness. Standardization insures minimized cost, equality of workmanship, uniformity of materials and a continuation of design. The General Vehicle Company produces six types, the capacities being 750 and 1000 pounds, one, two, 3.5 and

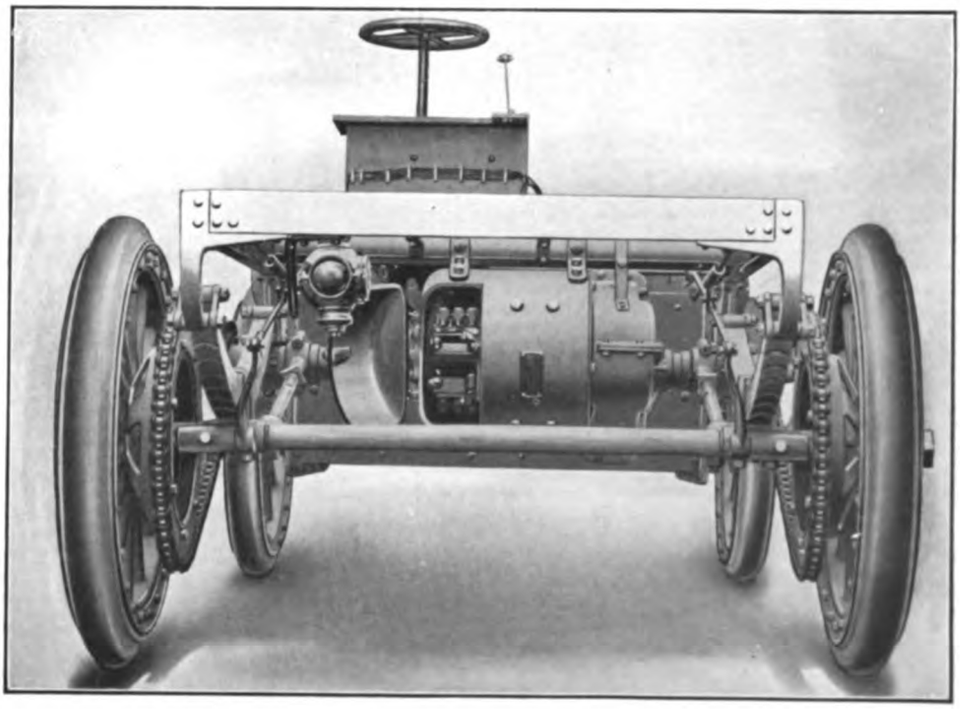
View of Standard Chassis as Seen from Below, Illustrating the Simplicity of Construction.

Digitized by Google

The General Vehicle Standard Motor with the Shell Opened Exposing the Commutator.

five tons, respectively. These are designed to meet the requirements of practically any delivery or haulage service.

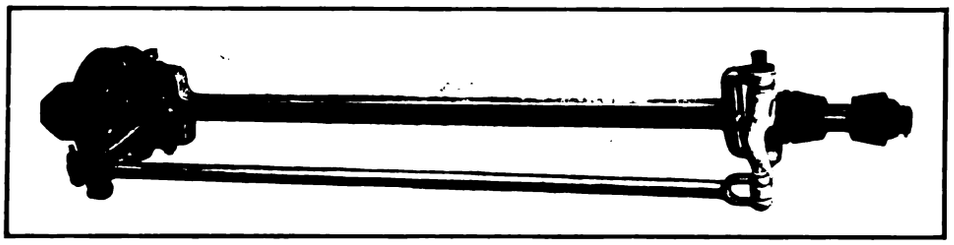
The speed in miles an hour for each vehicle is as follows: 750 pounds, 12; 1000 pounds, 12; one ton, 10; two tons, nine; 3.5 tons, eight; five tons, seven. The mileage radius of each vehicle in the order given is 45, 45, 45, 45, 40 and 35, respectively, with lead or acid batteries, and with Edison or alkali battery the radius is 45, 43, 54, 45, 40 and 40, respectively. It should be understood that the mileage is guaranteed for each wagon or truck, carrying a capacity load for half the distance. In other words the battery capacity of the vehicles is sufficient to carry a load from 17.5 to 22.5 miles and return with the acid installation, and from 20 to 27 miles with the alkali batteries, according to the type in service. Under normal conditions of operation the batteries will afford from five to six hours constant service of the wagons and trucks without recharging.



The General Vehicle Company's transports are extremely simple in design. They are, so far as the motor and controller are concerned, practically adaptations of the street car equipment, the only difference being that the street car is driven on the rails and the wagon is driven on the road, and that the energy of the latter is taken from a stored battery instead of from the charged wires. There is nothing complex or mysterious in this. The endurance of the street car motor is known of all persons, no matter whether they possess electrical or mechanical knowledge. With the street car equipment there is the possibility of the motor being "burned" by a short circuit because of the heavy voltage with which the feed wires are charged, but such happenings are rare considering the number of motors in use. With the motor used in the vehicle, however, there is no such probability because there is a limit to the capacity of the battery, and the motor is constructed expressly to resist an overload of 300 per cent. with entire safety. The motor cannot be damaged. The battery can be charged as often as is necessary, which is usually once the night of each working day. Charged and discharged with regularity the life of a battery is very long. As to the other working parts of the chassis there is nothing that will wear unduly. The components are not subjected to severe stresses and because of that fact have lengthy endurance.

Power Plant.

The motor or power plant of the electric vehicle is a standardized product of the General Electric Company, the largest maker of motors in the world. It is made to endure and it is given absolute protection by a cast steel shell or case. In this case at either end is mounted the imported annular ball bearing in which the armature shaft is installed, this minimizing the friction losses and insuring a high efficiency. The field pole pieces are a laminated iron construction. The field and armature coils are perfectly insulated and are made water proof. The armature shaft is tapered and the driving pinion is attached to it by a lock washer and nut. The commutator segments are of proportions that insure sufficient commutation with all loads and long life of all the parts. The brush holders are simple and enduring and graphite brushes are used, these being strong and yet offering little resistance to the current. A section of the motor case is mounted on hinges and it may be so tightly closed as to resist dust, water and oil, yet in a few seconds the interior of the case and the motor may be reached for examination or attention.



The motor is suspended from a large tubular cross member that is fitted to the chassis frame and it is given rigidity by a tubular member that corresponds to a torsion tube extending from the motor shell to the jackshaft housing. This may be noted in the bottom view of the chassis.

The jackshaft is mounted in self-aligning ball sleeves in heavy brackets fitted to the bottom of the chassis frame, the construction being such that the entire countershaft may be protected from stresses should there be distortion of the frame. The countershaft may be handled as a unit. Within the housing are the two short driving shafts connected with a differential of the spur gear type, these being mounted on four long roller bearings. The outer end of each shaft carries a sprocket. The drive is from the motor pinion to the differential gear by a Morse silent chain. This chain is enclosed in a water and dust proof housing and there is a large inspection hole at the side. The chain is driven in a bath of oil. The first reduction is by the drive from the motor to the countershaft and the second is from

Rear of Standard Chassis, Showing the Manner of Installing the Motor and Its Extreme Simplicity.

Digitized by Google

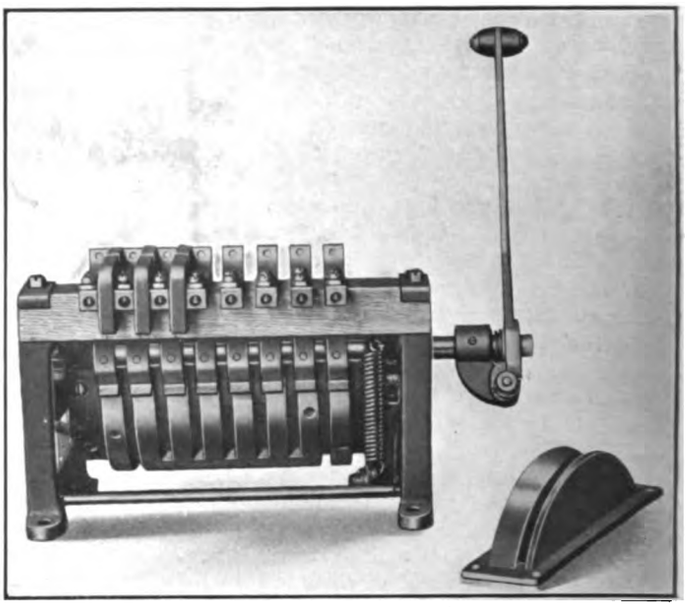
The Front Axle of the General Vehicle Chassis, of Sturdy Construction, and the Roller Bearing Spindle Equipment.

the countershaft by roller chains and sprockets on the rear wheels.

This is practically all the mechanism of the vehicle, aside from the wheels, steering connection, springs and brakes, so it will be seen there is construction of the simplest form.

Chassis Frame.

The chassis frame is of channel section pressed steel well braced with cross members. There is no difference with any type save in proportions, each being exactly alike. All connections of members are braced with vanadium steel brackets, all hot riveted. The countershaft brackets and the spring hangers are of vanadium steel, carefully heat treated. The frame carries the motor and countershaft as has been described and from it, forward of the countershaft, is carried the battery. This is installed in an iron box sheathed with wood to protect the metal from causes for deterioration. The weight is very low and the centre of gravity is correspondingly lessened, a very desirable quality with any vehicle.



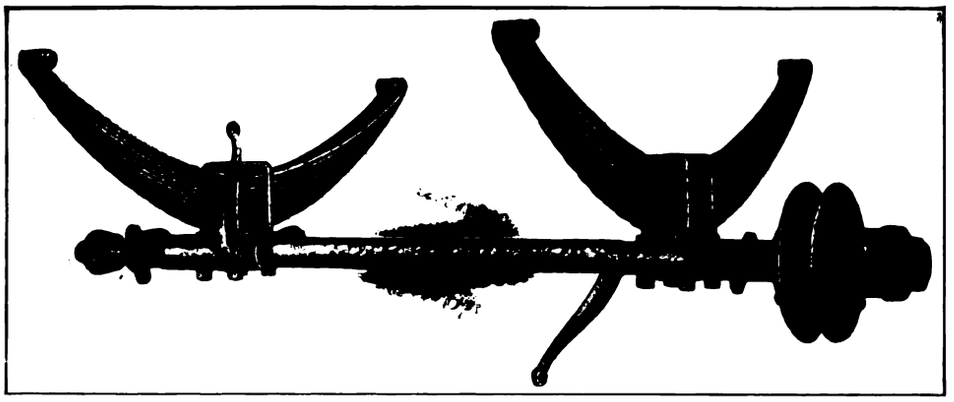
The frame is suspended on half-elliptic springs, oil tempered, that are as little curved as is practical and obtain sufficient clearance, the reduction of the curve minimizing the friction between the leaves. The rear springs are shackled at both ends, this affording the greatest degree of action without stress, the driving strain being taken by radius rods that extend from the dead rear axle to the countershaft housing, being fitted close to frame. The spring clips are heavy and the shackles and bolts are of a specially fine grade of material.

The axles are of 40-carbon, open hearth steel, the forward axles being I section and the rear axles tubular, of ample proportions. The wheels are all mounted on Timken roller bearings, which are packed with grease and require but little attention other than to renew the lubricant as occasion demands. The steering gear is a pinion and sector type, built by the company, the steering column being fixed to the chassis and the connections being made with universal joints. All wearing parts are bushed with steel and may be replaced as worn. Ample provision is made for lubricating all the moving members where they contact.

The wheels are an artillery type, fitted with solid rubber tires, dual members being used on the rear wheel of the larger and heavier trucks. The brakes are within drums carried on the rear wheels. They are of the internal expanding form and are operated by a pedal at the base of the steering post through a long rod connected with an equalizer and thence by linkage to the toggle levers that actuate the leather-faced brake shoes. The linkage is so compounded that a comparatively easy pressure will cause the wheels to lock. The means for adjustment of the brakes are in every way sufficient.

Battery Equipment.

The storage battery used has been standardized. It is always composed of 44 cells, ranging from nine medium to 21 medium plates to a cell, contained in from four to six crates. The capacities range from 112 to 280 ampere-hours.



The Controller by Which the Movement and the Speed of the Chassis Are Governed.

The battery cradles are deep enough to permit the use of high bridged jars, with two bridges each 2.75 inches high. The same size of wood and rubber separator is used between the plates in all batteries and the electrolyte has the same density. The rubber jars of differing sizes have the same thickness of wall, and the elements fit exactly all jars, making for complete interchangeability.

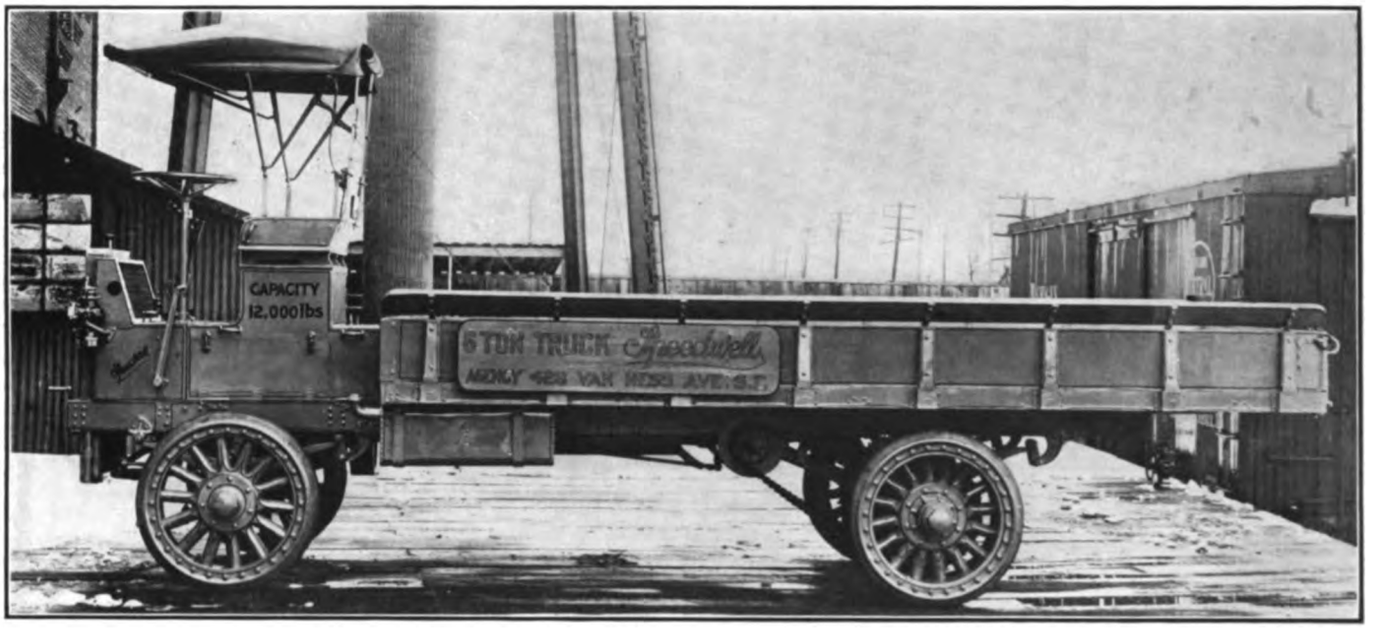
The motors are rated by number and are standard with voltage of 85, but the amperage varies from 16 with the 750-pound wagon to 40 with the 3.5 and five-ton trucks. The 750-pound wagon motor is rated at 1600 revolutions and the 1000-pound wagon motor at 2000, but the others are uniform at 1200. The figures are for the lead or acid batteries, and do not apply with the Edison or alkali battery.

The controller is the continuous torque type built by the General Electric Company and it is exactly the same as those used in

The Rear Axle and Springs, Showing the Roller Bearing, Wheel Hub Flange and the Levers for the Internal Expanding Brake.

Digitized by Google

street railway practise, save that it has the axis of the rotable insulated semi-cylinder parallel to the horizon instead of vertical, as with the street car installations.



On the circumference of the semi-cylinder is a number of copper contact blocks arranged to make the desired connection with the copper fingers of the controller, which are connected with the terminals of the battery, resistance and the motor. This controller is placed beneath the driver's seat and it is actuated by a lever that is at the side of the operator. There are four forward speeds and two reverse, and the method of operation is simply pushing the lever in the direction one wishes to move. The motor speeds are changed by degrees and there is no shock or sudden engagement of the motor. The wiring systems between the controller and battery, the battery and motor, and the motor and controller are substantial cable, thoroughly insulated so as to be protected against water, oil, mud and acid. The cable is firmly secured to a wooden member and cannot be shaken loose or affected by the vibration of the chassis.

It will be seen that there is nothing that will produce complications in the electric vehicle chassis. The control is so simple as to be surprising to those who begin to drive them. There is a steering wheel, a single pedal that operates the brake, and the controller handle that controls the motor. There are no gears to shift, and no other pedals to push, or hand levers to move. The condition of the battery is indicated by an ammeter, or a sangometer. When the driver leaves the vehicle he turns a switch and machine cannot be started until the connection is again made.

The electric vehicle is the acme of simplicity. It is clean, it is suited for any form of haulage, and it has every quality in service that could be desired to the limitations stated.

SPEEDWELL REPLACING MULE WAGONS IN CALIFORNIA.

WHAT is believed to be one of the largest haulage problems to be undertaken by mechanical transports, and one involving approximately 260,000 ton-miles, is being solved by a fleet of six Speedwell trucks of six-ton capacity, made by the Speedwell Motor Car Company, Dayton, O., the contract having been closed by L. V. Lynch, who is the company's distributor for northern California.

One of a Fleet of Six-Ton Speedwell Trucks Replacing Mules in Hauling Material for Construction of Huge Dam in Plumas County, Cal.—Over 10,000 Tons Will Be Handled in 200 Days.

The machines will be utilized to transport tonnage consisting largely of cement and lumber, in addition to the commissary supplies for the army of men engaged in the construction of the huge storage dam of the Great Western Power Company at Big Meadows, Plumas county, California. All supplies, etc., will be hauled from Keddie, a distance of 26 miles and over narrow mountain roads abounding with treacherous curves and steep grades. Previously, this work was performed by six and eight mule teams, these averaging a round trip in three days, because of the roads.

Some idea of the amount of material to be hauled may be gained from the announcement that the reservoir made by the dam will be the largest artificial body of water in the country and it is estimated that over 1,000,000 feet of lumber will be required, to say nothing of tons of cement.

Before accepting the order for the trucks, R. Harry Croninger, manager of the truck department of the Speedwell Motor Car Company, and L. V. Lynch, went over the ground very carefully, for the character of the roads and country presented an application different from the ordinary commercial work. In many sections the roads were found to be too narrow to permit of two machines passing and this added to the complications. After studying the situation with the engineers of the Great Western Power Company, the Dayton concern stated that its product could handle the work successfully and economically.

It is proposed to run the trucks in fleets on scheduled time as with steam trains, and teach the other users of the highways the time when the cars will be at passable points. Each power wagon will be equipped with a powerful electric signal which can be heard three miles and it is believed that the signals will be understood readily.

It is estimated that the saving to the highways by the substitution of motor cars over the mule equipment will be considerable. With the latter was employed a wagon having three-inch steel tires, which materially affected the road, but with the trucks this same tonnage or pressure is carried on a surface of 12 inches of rubber.

THE A B C OF MOTOR TRUCK OPERATION.

A Simple Exposition of the Principles Underlying Operation, Maintenance and Repair of All Motor Driven Commercial Cars, Describing Details of Their Components. Part XVIII—How Power Is Transmitted to the Rear Wheels.

By C. P. Shattuck.

HAVING explained how energy is developed and outlined the function of the clutch and transmission, the next logical step is the method utilized for transmitting the power of the motor to the driving or road wheels. The final drive is an important factor in motor car construction and may be stated to comprise two systems, one employing chains and sprockets and the other a shaft, universal joints and bevel gearing. There are also combinations in which both chain and gearing are utilized. The arrangement of the components of the chassis varies; that is, the power plant may be located in front under the hood and energy transmitted by means of a shaft to the transmission and thence through another shaft to the driving axles, or the motor may be located amidships and the countershaft driven by a single chain and final drive by double members. Although variations exist the basic principle is the same, the designer seeking to obtain the maximum efficiency in the method of drive.

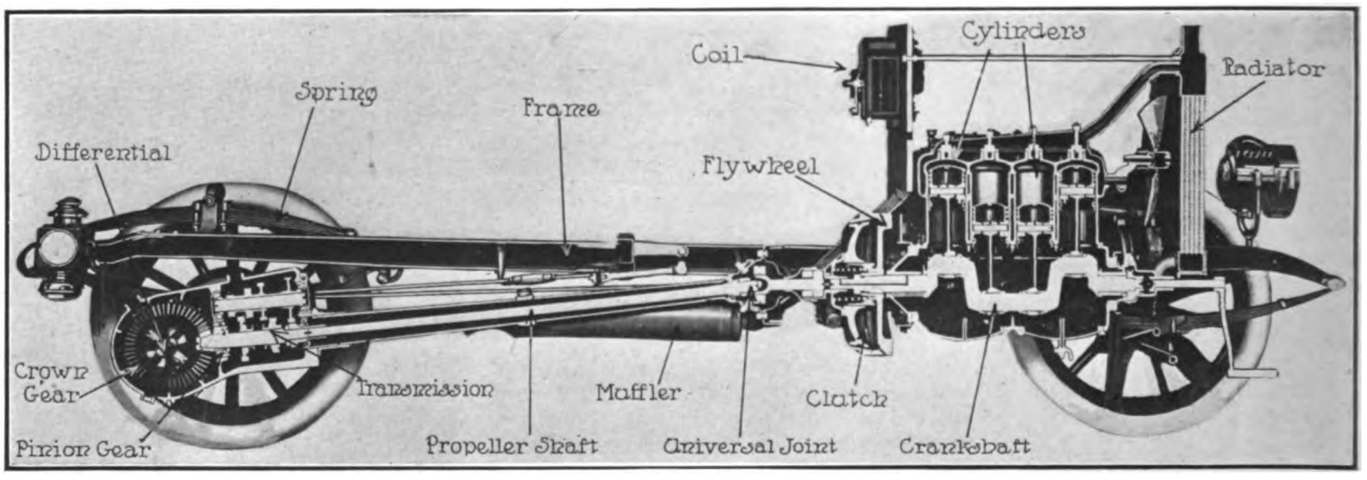

Fig. 74—Chassis of Pleasure Vehicle Bisected to Depict Utilization of Shaft Drive and Live Axle.

Types of Chain Drive.

The chain drive may be sub-divided or classified under two heads; namely, the single chain and live axle, and the double chain and solid or dead axle. Upon cars employing the single chain and live axle, so-called because the road wheels revolve and rotate with it, the latter is usually a cylindrical shaft of steel divided into two parts, to each end of which is attached one of the road members. Between these axles are located the differential or compensating gears which perform the same function as the fifth wheel of a horse drawn vehicle, that of permitting the machine to turn corners. The driving axles are enclosed in a steel tubing made in two sections, and provision is made for the differential and sprocket as well as for securing the axle housing. The latter is sturdily constructed to withstand stresses and so arranged that it may be disassembled for repairs or adjustments.

The axle tubing has supports or spring pads upon which rest and are bolted the springs, and the housing also carries the bearings upon which the axles revolve. These may be of the ball or roller type and usually consist of four members, one on either side of the differential and one under each spring. Energy from the motor is transmitted through the medium of a small sprocket attached to an extension of the crankshaft, and thence by a chain to the larger sprocket on the rear axle. The former is not rotated at the crankshaft speed, the ratio being approximately 3.5 to one; that is, the smaller sprocket makes 3.5 revolutions to one of the large member. For example: The small sprocket may have 12 teeth and the larger 42. Any number of ratios may be obtained by employing different sized sprockets on the driving shaft on which is carried the planetary transmission. This type of drive is utilized on light delivery cars, and of the design it may be said that power is transmitted to the rear wheels with a minimum loss.

The double or side chain drive is generally employed on mechanical transports of large tonnage, and when this form is utilized the rear axle is of the solid or stationary type, and is similar to the axle of the horse drawn vehicle, inasmuch as the wheels revolve on ball or roller bearings. Bolted to the inside of the spokes of each wheel is a large sprocket and upon the frame of the car is mounted a cross shaft known as a counter or jackshaft. This carries at each end one of the smaller sprockets, from which the power is transmitted by chain to the sprocket located on the rear wheel.

Fig. 78 outlines clearly the solid type of rear axle and the large sprocket on the road wheel and the manner of attachment. It will be noted that the axle is substantially constructed and attached to it are the springs, these in turn being secured to the main frame by shackles. In the illustration the wheel is shown removed to expose the end of the axle which is equipped with roller bearings, and the driving sprocket and chain is also outlined. The assembled components are also depicted, and it is obvious that some arrangement is essential to permit the vehicle to turn corners.

Location of Countershaft.

Reference has been made to the countershaft and this member is outlined at Fig. 75. It will be noted that it is

Digitized by Google

constructed in two parts or divided near its central portion, which is enlarged to permit of the installation of the compensating gears. In this design power is transmitted from

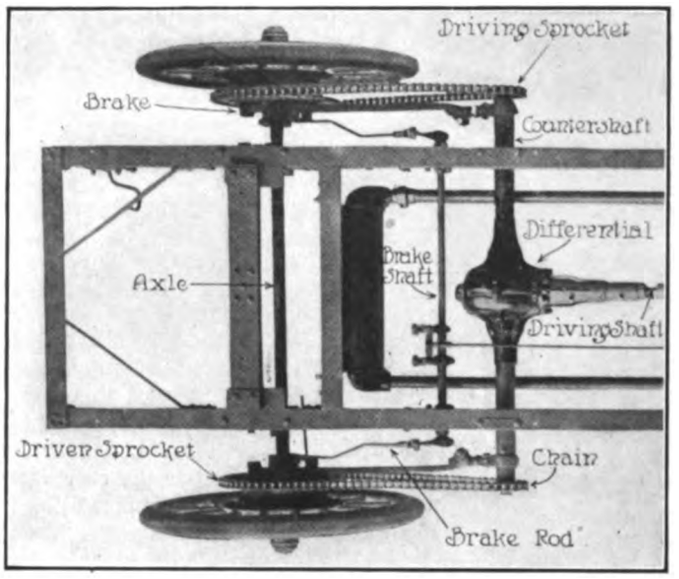

Fig. 75—Outlining Application of Double Chain Drive and Location of Countershaft.

the last gear of the transmission, thence through a shaft to another gear or pinion which rotates the crown gear and subsequently the jackshaft. The latter revolves in ball or roller bearings and its design varies, although the principle involved is similar. To prevent the binding of the countershaft through possible distortion of the frame, a flexible joint is usually provided and in some designs two are employed. Provision is made for lubrication in the form of grease cups or oil holes.

As previously explained, the location of the transmission and differential varies. In some designs these components are a unit as at Fig. 76, which outlines the differential member, also the driven countershaft. This arrangement makes for compactness and strength and the components are protected from dust and mud. Energy from the motor is transmitted through a shaft having universal joints, thence through the mainshaft of the transmission to the driving bevel. The latter rotates the crown gear which in turn imparts motion to the countershaft on which is fitted the sprockets actuating the chains to the sprockets fitted to the road wheels.

Advantages of Chain Drive.

The double chain drive presents many advantages, inasmuch as the axle which carries the load is a solid piece, and being stationary is suitable for supporting heavy loads. The differential mechanism upon its divided shaft is entirely relieved of any weight or shock resisting functions, and may be completely enclosed and operate in oil. For very heavy trucks the double chain drive is indorsed by engineers, and when the chains are enclosed to protect them from dust and mud, the drive is very efficient as loss by friction is reduced to a minimum.

As there is a strong forward pull transmitted to the rear axle by the chains when power is applied, it is obvious that some method of counteracting this force must be incorporated to prevent the axle from moving forward relatively to the rest of the vehicle. Two distance or radius rods are provided for this purpose and consist of tubes or solid members, the rear ends of which are attached to the axle and the forward portions secured to the frame of the machine, at points not far out of line with the front sprocket. These rods are made adjustable, and by loosening or tightening, the driving chain may be adjusted correspondingly, thus securing perfect alignment of the road wheels. Figs. 78 and 79 outline these distance rods and the manner of attachment.

The principle of the shaft drive is similar to that of the chain with live axle, the difference being in the method of transmitting the energy of the motor to the rear or driving axles. Instead of a sprocket wheel being fitted to the differential mechanism, a bevel gear is employed, although a variation is noted in the worm drive, described and illustrated herein.

The principle of the shaft drive is outlined at Fig. 74 which presents the chassis of a pleasure vehicle bisected squarely in the middle from top to bottom. It will be noted that power is transmitted through the clutch, thence through a universal joint and shaft to the transmission. A shaft of the latter is fitted with a bevel gear carrying teeth, the faces of which are cut in lines parallel to the direction of the shaft, upon which it is secured. Mounted with the differential is a larger gear or crown member with which the smaller pinion is in mesh. This arrangement is necessary when it is desired to connect by means of gears two shafts at right angles to each other; that is, the faces of the gear teeth are at an angle or bevel with the shafts upon which they operate, the sum of the angles of the tooth faces with their respective shafts being equal to the angle between the two shafts. The ratio of these gears is obtained by dividing the number of teeth on the larger member by the smaller pinion as with the chain drive.

Because of the slight variation in the distance from the point of attachment of the drive shaft to the speed changing mechanism, the point of contact of the two bevel gears changes slightly on account of the relative movement of the axle and car, and the shaft is provided with flexible joints. These members also serve to compensate the line of drive, and the amount of wear depends upon the drop; that is, how far below the level of the crankshaft is fitted the bevel or driving gear.

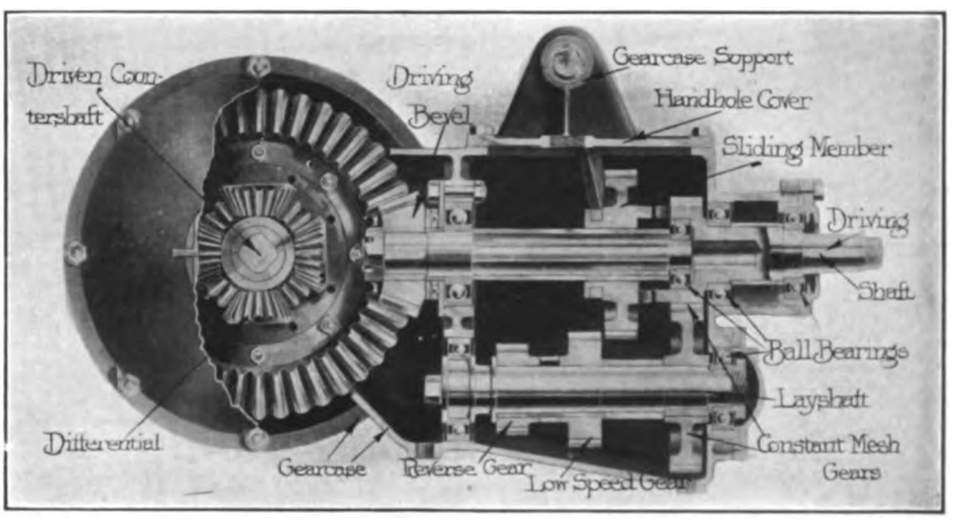

Fig. 76—Depicting the Differential and Transmission as a Unit, Also the Countershaft and Its Components.

When power is applied the tendency of the smaller gear

Digitized by Google

is to force the drive shaft forward and to push that portion of the differential to which the larger gear is attached away from itself. To prevent this lost motion, thrust bearings

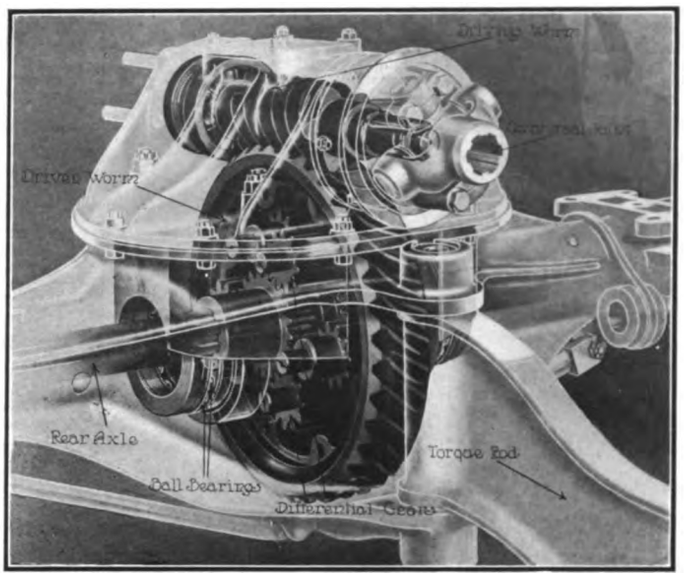

Fig. 77—The Worm Gear Drive, Having the Advantage of High Reduction with Small Sizes and Making for Quiet Running.

are fitted and these generally take the form of rows of steel balls, bearing upon hardened surfaces in such directions as to take care of the thrust. Ball or roller bearings are utilized to support the driving shaft which rotates in a hollow tube and provision also is made for the lubrication of the working parts. Radius or torsion members are fitted as with the chain drive system.

Various types of rear axles are utilized with the shaft drive and among these is what is known as the full floating type in which design the differential bearings are mounted on the hub of the differential instead of directly upon the shaft. The outer ends of the axle housing are so constructed as to permit of the mounting of bearings of sufficient capacity to support the weight of the vehicle through the medium of the driving wheels. This arrangement permits of the withdrawal of the axles or driving shafts without removing the wheels or jacking up the rear system. The road wheels are actuated by jaw clutches; that is, the outer end of each shaft is provided with jaws which mesh with recesses in the hubs of the road wheels. This design makes for easy inspection of the components and disassembling as well. There are other forms of floating types such as semi and three-quarter, also rear axles having bearings similar to that of the single chain drive with live axle previously referred to. With these types the wheel is secured to the driving axle which in turn is supported by bearings contained in the housing.

Worm Drive.

A method of final drive which differs from those of usual construction is the worm which is depicted at Fig. 77. This design is favored abroad and was adopted and successfully applied in this country, by a prominent maker of pleasure vehicles, to a commercial car.

The worm and gear has been utilized for many years in the steering system of automobiles and was supposed to be absolutely irreversible, a desirable feature when thus employed. The worm and gear, however, is constructed so as to be reversible and when substituted for bevel gears in a shaft drive with a live axle, has the advantages of high reduction with very small sizes, straight line drive, and the elimination of friction losses through universal joints. In addition, it has a reputation for quiet running. With the mechanical transport a greater reduction from engine speed is more desirable than with the pleasure vehicle, and the ratio of the gears in the illustration is approximately about eight to one. It will be noted that this design includes a torque rod for taking driving and braking strains, while the usual radius rods are fitted to relieve the springs of all tractive effect.

Internal Gear Drive.

Another form of drive and rear construction which may be said to embody the advantages of the solid rear axle utilized with the double chain, yet employs a differential and shaft as with the live axle, is the internal gear drive outlined at Fig. 79 A. It will be noted that the rear axle supporting the load is of the solid type and is turned down at the ends to form the wheel spindles to which are fitted roller bearings. Just inside of each spindle is a spider shaped casting which is utilized to support the differential axle, form the spring seats and provide a hub in which the radius rod is inserted.

The driving mechanism is depicted at B, this consisting of a housing carrying the differential and driving shafts and its operation is similar to the countershaft of the double chain drive with the exception that a spur pinion is fitted to either end instead of a sprocket. Each of these pinions meshes with a large internal gear bolted to the inside of the road wheels and the entire mechanism is enclosed and operates in grease, being dust and weather proof. The two radius rods unite toward the middle of the car in a single ball joint, which arrangement takes care of all stresses when operating over rough roads.

Function of the Brake.

With any mechanical conveyance it is essential that some means be provided for bringing the moving vehicle to a stop, and with the motor car this is accomplished by friction through stationary bands or shoes being brought

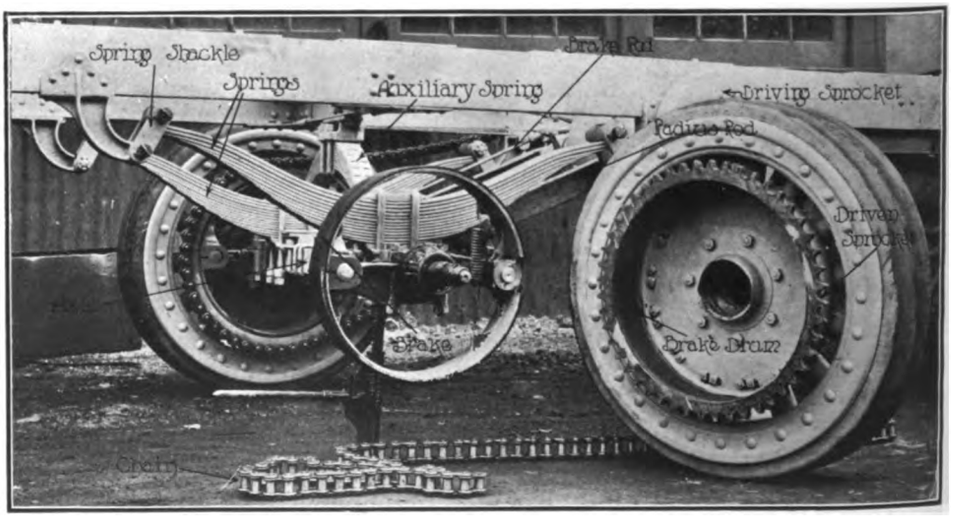

Fig. 78—Conventional Type of Solid Axle Utilized with Double Chain Drive, with Wheel Removed to Show Driven Sprocket, Axle and Brake.

into contact with some revolving part of its mechanism which is in motion at all times that the vehicle is running. Brakes are classified according to their construction as con-

Digitized by Google

tracting band members or those of the internal expanding type, and they may act as hub, differential or transmission brakes.

The band brake consists of a strip of thin metal lined with frictional material and so arranged that its ends may be drawn together by means of a powerful toggle arrangement. This binding strap encircles a metal drum or pulley, attached to some part of the mechanism which moves when the car is in motion. When the band is contracted through the action of the toggle, which is operated by a pull rod in turn connected to a pedal or lever, the lining of the band grips the drum producing the desired friction. One of this type is outlined at Fig. 79.

The internal expanding brake, a form of which is depicted at Fig. 78, is favored because of its double acting qualities and the less liability to drag upon its drum. It consists of two semi-circular metal shoes, which conform to the inside surface of the wheel drum and are fitted with springs to prevent them from coming in contact with the drum when not in service. The members may be expanded by either a cam or toggle arrangement and when properly adjusted so as to provide an equal frictional effect are very dependable.

In order that an equal pressure may be exerted to both brakes a device known as an equalizer is incorporated, this member tending to divide the braking effect equally between the two wheels. Two sets of brakes are usually provided, one being the service member operated by pedal and an emergency actuated by a hand lever. These may be fitted with a locking device by which the brake may be held at any desired degree of pressure. The emergency brake may also include means for throwing out the clutch when the member is operated. With the commercial vehicle, transporting as it does, heavy loads it is imperative that the brakes be well designed and substantially constructed. The width is such that many square inches of braking surface are obtained, and provision is also made for taking up wear. Efficient members are equipped with springs which hold the bands in a normal position until pressure is applied, also preventing undue friction as well as wearing out the lining.

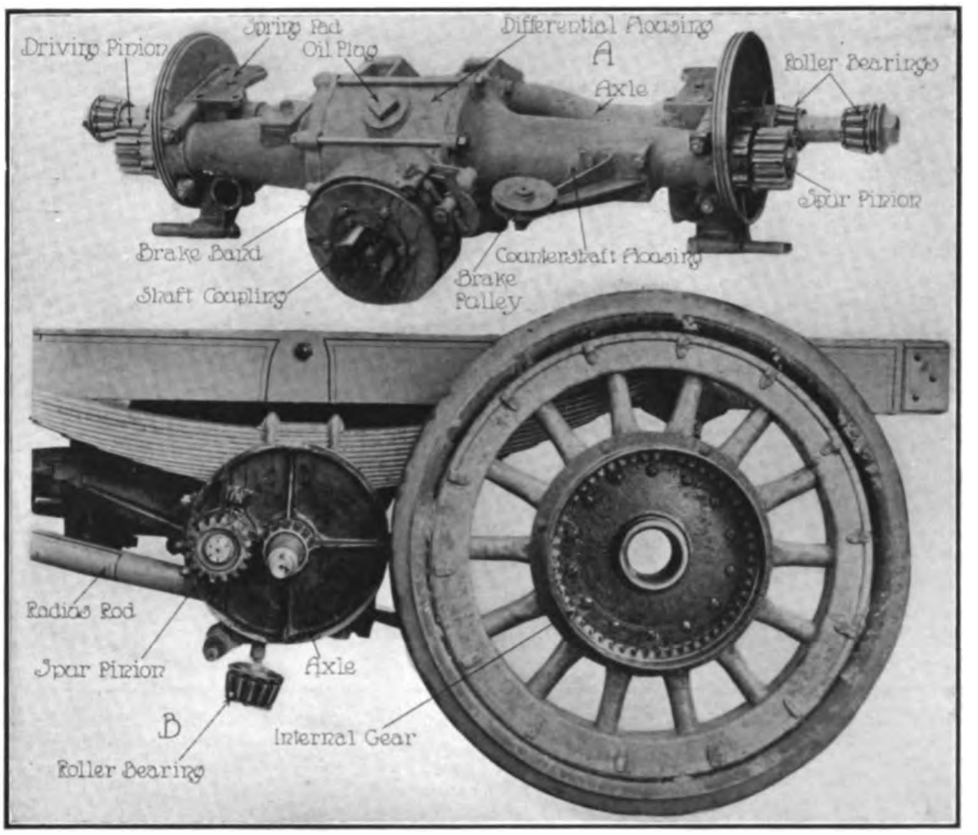

Fig. 79—Illustrating the Internal Gear Drive, Combining the Advantages of the Solid and Live Axles, the Former Carrying the Load.

(To Be Continued.)

Ed. Note—The next installment will deal with the function of the differential and the steering systems utilized.

NEW ENGLAND PURCHASES INCREASING.

The purchases of motor trucks in the New England States have increased rapidly in the past year and a half, according to William P. Kennedy in an address before the Electric Luncheon Club, Boston, recently. Mr. Kennedy gave some exceedingly interesting statistics. The trucks placed in service in New England up to Sept. 1, 1911, reached a value of $10,000,000, of which 30 per cent. had been placed in service during the preceding 12 months. The pleasure car total is three times this, or $30,000,000. According to Mr. Kennedy, the business of the six months from December last to March indicates that last year's record is to be exceeded by 50 per cent., and that there will be in operation in New England by Sept. 1, 1912, some $60,000,000 worth of vehicles.

DAILY ROAD PATROL.

In these days when motor transportation between cities is more dependent upon the roads than upon the trucks, any new road improvement scheme should prove of decided interest. The Middlesex Automobile Club of New Brunswick, N. J., has proposed a systematic daily examination of the highways in its vicinity. The idea is to establish a road patrol which shall go over every mile of the highway every day and correct at once minor faults before they grow larger. The club has appointed a committee to confer with the Board of Freeholders, and it is hoped that the two bodies will be able to co-operate in patrolling the roads. The expense will no doubt be large, but it should be remembered that there will be considerable saving in repair work, for the patrol will be able to work on bad spots as soon as they appear, before they grow so large as to necessitate extensive repairs.

ADVERTISING BY MAIS TRUCK.

A Mais, made by the Mais Motor Truck Company, Indianapolis, Ind., is to be used in an advertising scheme, and will go over the Premier ocean-to-ocean route from Indianapolis westward. Hugh Annis will be in charge of the expedition, and five men will constitute the crew. The truck will carry wireless apparatus, telegraph and telephone sets, a typewriter, and camping outfit.

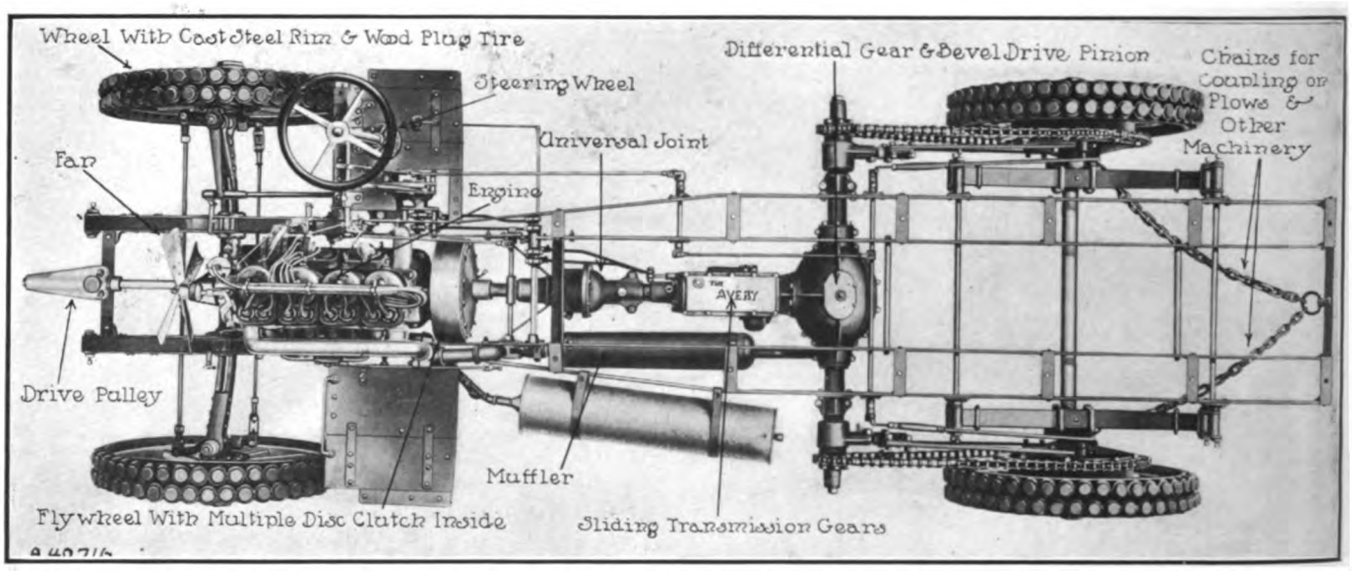
MOTIVE POWER FOR THE AVERAGE FARMER.

Solving the Problem of Furnishing a Satisfactory Vehicle That Not Only Will Do the the Ordinary Field Work, but Carry Loads on Its Own Body—Success That Has Accompanied the Use of the Avery Farm Trucks.

CAN the average farmer, the man with 500 or 600 acres of land, utilize a gasoline truck to advantage in undertaking his general field work? That the larger tractors have been accomplishing splendid results on the farms containing thousands of acres on the broad prairies of the West and in Canada, is more or less well known, but there appears to be a lack of information concerning the vehicle which is adapted for similar usefulness on the so-called small farm. Undoubtedly, there are numerous questions which must be given careful consideration before the horse is entirely abandoned, but at least one manufacturer, the Avery Company, Peoria, Ill., claims to have reached a decidedly satisfactory solution to all these problems in its Avery farm truck.

The argument against the horse may be summed up as follows: It costs too much to feed, it takes too many men to operate, it takes too long to do the work, it is subject to weather conditions, diseases and accidents, and it takes up too much time in care and attention.



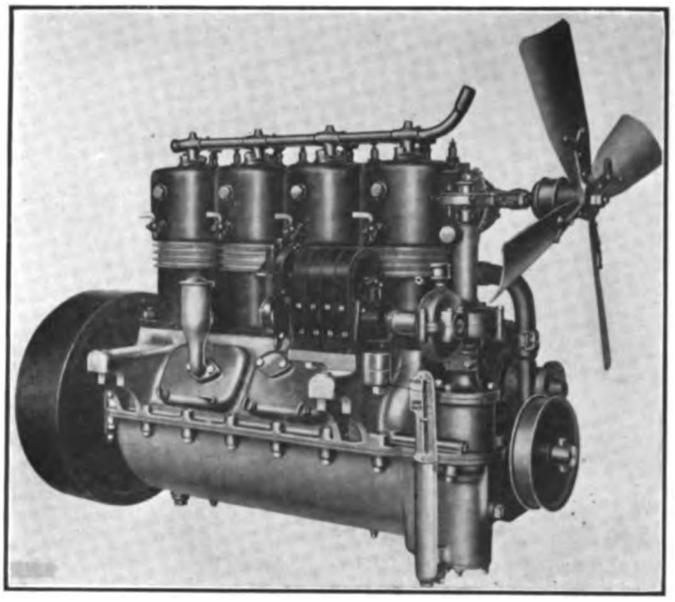
It is maintained that it takes the crop from one acre in five to feed the horses necessary to do the work. The Minnesota Agricultural Experiment Station has discovered that the average annual cost of maintaining the average farm work horse is $80, and for this cost, the animal gives a return in work averaging about three hours a day throughout the year, at a cost of about eight cents an hour on the average Minnesota farm.

One man can handle from two to four horses and do it right. It is becoming more and more difficult each year to hire good help, and each year the wages are increasing.

In order to make good profit from farming these days it is necessary to use up-to-date farming methods, which means that the farmer must plow quickly and to the required depth when the ground is in just the right condition, and that it must be cultivated several times over in order to make the best possible seed bed and to hold the moisture. It is an impossibility to go over the ground enough times and quickly enough with horses to raise as many bushels as must be raised to the acre.

Little need be said respecting the liability to accidents and disease, or the effect of weather conditions upon horses. In the matter of care and attention: At night, it is unhitch, unharness, water, feed and bed a lot of tired, sweaty horses. In the morning, it is feed, water, curry, harness up and hitch up. At noon, it is unhitch, water, feed and hitch up. Even when they are not at work, they must have care in order that they may be in condition when needed. And they must have the same care on Sundays and holidays.

More might be said concerning the drudgery of farm work, but the use of modern farm implements already has eliminated some of this. The present generation has seen the passing of the plodding oxen dragging the single plowshare across the field, while the farmer hit the hook a kick with his cowhide boot in order to turn it over at the end of the furrow. For a time the horse succeeded the ox in this work, but nowadays the farmer sits on a wheel plow and turns the shares with a lever. The introduction of the gasoline truck appears to be but another step in the onward march of progress.



Chassis of Avery Farm Truck with Principal Parts Outlined to Indicate Their Position and Relation to Each Other.

The Avery Farm Truck.

The Avery farm truck is claimed to be the only machine designed and built for farm work, which will haul loads on its own body. It is the result of long experimentation, with the object in view of creating a power machine which will enable the farmer to do his work at less expense, at the right time, in the right way, and in a manner to relieve him of the troubles and faults of horse power. The method of meeting the various problems involved will appear with a description of the vehicle and citation of some of the work already accomplished by these machines in actual service.

For such work as is contemplated by a vehicle of this nature, it not only is essential that the motor shall deliver its power under unusual conditions when plowing and hauling, but it is particularly desirable that it shall operate at its maximum efficiency under load without heating while

Digitized by Google

Avery Motor, Designed to Present Exceptional Cooling Facilities.

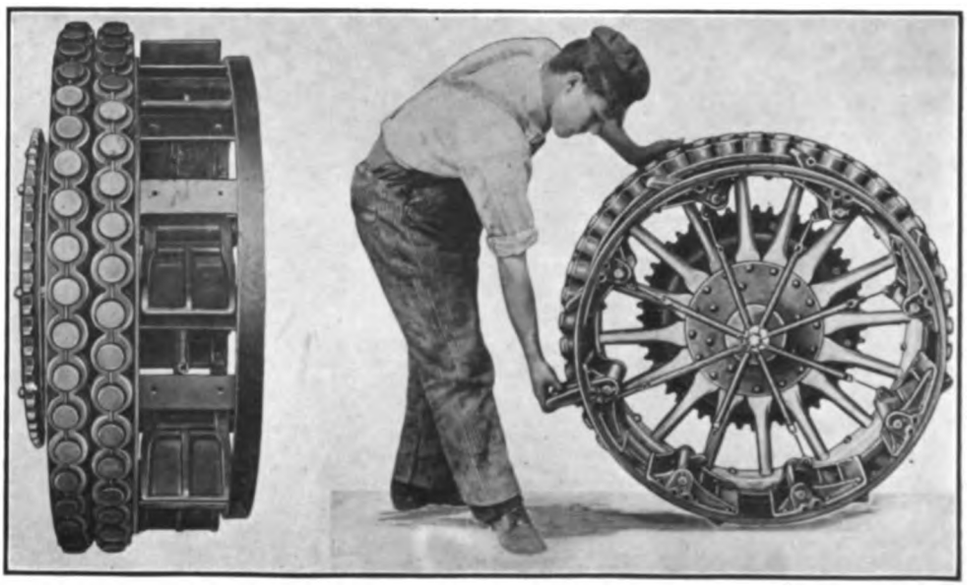
working as a stationary engine in sawing wood, threshing, etc. In this respect the designer of the Avery farm truck has lost no opportunity to provide for every possibility. Particular attention has been paid to the matter of cooling.

In the first place, the motor employed is a four-cylinder, four-cycle, water-cooled unit of the vertical type, placed forward under a hood and easily accessible. The bore is 4.75 inches and the stroke five, giving a horsepower of 45 under a brake test. However, the machine is rated at 12 horsepower in tractive effort for pulling loads, and it is held to be possible to obtain any speed from two to 15 miles an hour.

Provisions for Cooling.

The cylinders are of the L head type cast separately and with their entire surface exposed, permitting equal expansion and contraction of the metal on all sides. Liberal water jackets have been supplied, and petcocks are provided at the lowest points, as also is true of the radiator and pump, so that all of the water may be drained from the entire system, should it be found desirable to put the truck up for the night without resorting to the use of an anti-freezing solution before cold weather actually begins.

An additional feature in the cylinder construction is the utilization of four radiating fins below the water jacketing on each member, these providing for supplemental cooling somewhat on the principle of the air-cooled motor. Thus, not only is the combustion chamber thoroughly cooled by water but that portion of the cylinder below also is maintained at a proper temperature by these radiating fins.



It is claimed by the company that its cooling system will keep the motor cool even when the truck is being used in the severest work. This comprises a honeycomb radiator of large capacity, placed in an upright position in front of the motor, and a fan just behind this. A positive gear pump keeps the water in circulation, even when the engine is running at a low rate of speed. Nine gallons of water are thus forced through the manifold, entering the cylinders near the valves, so that the coolest water strikes the hottest part of the cylinders first. In connection with this, the fan is driven by a one-inch belt from a pulley, and means are provided for automatically adjusting the tension.

Motor Construction.

Inasmuch as the moving parts of the power plant are subjected to stresses not usually encountered even with commercial vehicles, special effort has been made to insure that these shall be retained in perfect alignment at all times. The crankshaft, for instance, is a drop forging, accurately turned and trued, and fitted with five bearings, the object being to hold it in position under the most severe strains. The same thing applies to the camshaft, also a drop forging with integral cams. After forging, this is machined and hardened, then reground to prevent the possibility of using a shaft which might have been drawn out of alignment during the hardening process. The connecting rods are steel forgings, each having large bearings at both ends.

All valves are accurately ground and are of the adjustable type, this being accomplished by a lock nut arrangement. The motor is fitted with so-called clean-out plugs at the top of each cylinder, by turning which with an ordinary wrench, it is possible to loosen and remove any carbon deposit with a small instrument and without dismantling the motor. In addition, each cylinder is provided with a priming cup, making it unnecessary to remove any of the spark plugs should priming be necessary in cold weather, and liberal inspection plates are fitted to the upper half of the crankcase. Thus the designer has taken into consideration that the truck may be placed in the hands of those unaccustomed to working upon the automobile power plant and the labor incidental to proper care has been reduced to a minimum.

Simplicity is combined with sturdy construction throughout. The lubrication is by a combination force feed and splash system in which all the operator needs to do is to pour in the oil. Below the crankcase is a sub-tank or sump, into which the oil is poured, and from which it is constantly forced through a .5-inch pipe perforated along its sides, by a positive gear pump. This pipe sprays lubricant onto cranks and bearings and into the cylinder casings. The cranks also dip into the lower crankcase and aid in the distribution to all working parts. The constant level is maintained in this lower crankcase, the overflow running into the sump. An

Two Views of Avery Wood Plug Tire and Wheel Extension, Illustrating Method of Bringing Lugs into Action.

Digitized by Google

William Larson Utilizes Avery Farm Truck to Pull Three 14-Inch Plows at the Rate of 10 Acres a Day on Short Land.

oil gauge permits the driver to determine the exact level at a glance.

Two sets of spark plugs are fitted, ignition being by a double system, employing a magneto and storage battery. The company calls attention to a feature of this system, by which it is possible to connect either the battery or magneto readily with either set of plugs, so that it is never necessary to run the engine with one or more cylinders missing, even though the battery may be weak and the magneto plugs are not working properly. The gasoline capacity is 23 gallons.

Clutch and Transmission.

The clutch is a multiple disc member of the Avery Company's own design and manufacture. It consists of 13 discs, six of which are of 13 inches diameter and the other seven a trifle smaller. These are contained within the flywheel and run in oil, this not only acting as a lubricant but serving as a cushion and causing easy engagement and release.

The transmission is of the selective sliding gear type, simple in construction and silent in operation. The design is such as to provide three speeds forward and reverse, these changes in speed being effected with ease. The extra large gears are made of special alloy steel, accurately cut and tested for hardness. These operate on Timken roller bearings, which reduce friction to a minimum. Between the clutch and transmission is a universal joint of ample size, housed in a dust proof casing and running in oil. This aids in keeping the main components of the generation and transmission of power in exact alignment under the most severe conditions of service.

The countershaft is large, running on Timken roller bearings. The bevel drive gears also are extra large to meet the requirements of their work and are made of the very best alloy steel. Every gear is accurately cut and tested for hardness before being assembled. They are housed oil tight and dust proof, and it is claimed that hard service will disclose no appreciable wear except a brightened tooth.

Final drive is by double side chains to the rear axle, which is 2.75 inches in diameter. The drive sprockets are fitted with 13, 17 or 20 teeth in front and 51 or 58 in the rear, although any combination which will best suit the work can be furnished, and extra sets are supplied without charge. These are made interchangeable, as also is true of all parts throughout.

In a vehicle of this nature it is absolutely necessary to provide efficient brakes, which shall be capable of holding the truck on the steepest grade or for exceptionally quick stopping, the latter being particularly true when engaged in plowing land in which stones or stumps are liable to be present. Each rear wheel and each end of the countershaft is provided with an internal brake of the expanding band type. Those on the wheels are 16 inches in diameter and have three-inch faces, while those on the countershaft have diameter of 12 inches and faces of two. The wheel brake shoes are held by double radius bars extending to the countershaft, and thus the strain of stopping the truck comes on these radius rods rather than on the rear axle and springs.

Brakes, Frame and Springs.

The frame is composed of four five-inch steel plates, with cast steel spread blocks between each pair of plates, all riveted together, making a strong and rigid, though flexible assembly. An accompanying illustration shows plainly the general construction of the framework and the location of the working parts. It will be noted that the

J. F. Sweany of Stafford, Kan., Shelled 800 Bushels of Corn, Employing His Avery Farm Truck as a Stationary Engine.

Digitized by Google

front is narrowed, which permits of a wide swing of the front wheels and makes possible short turns, such as are required in plowing, etc. A double rod connects the steering arms, one in front of the axle and one behind, this construction being for the purpose of preventing accident in case one arm or one rod should become broken. The steering gear is of the standard automobile design, and offers no complications for the inexperienced operator.

The entire load, motor, transmission and frame, is carried on strong leaf springs, those in the rear having 13 leaves three inches wide, and those in front having 11, 2.5 inches wide. Wheels are 41.5 inches in diameter. The wheelbase is 140 inches and the tread 62. The regular bed is of hard wood, 52 inches wide and 123 inches long. The carrying capacity is three tons, and the net weight with platform and 20-inch box is 5875 pounds. Special bodies may be fitted upon order.

Novel Wheel Equipment.

A particular feature of construction is to be found in the tires. The wheel rim is of cast steel, perforated and filled with two-inch round hard wood plugs, driven in securely. These plugs are placed diagonally across the face of the rim and form a smooth surface, the steel rims and wood plugs providing the necessary grip for travelling over soft plowed ground or muddy roads. It also is claimed that they run over hard roads, macadam surfaces or paved streets without injuring them in any manner. The plugs will wear for a long time when travelling over ordinary dirt roads or in the field, and can readily be driven out and replaced at small expense, when it is necessary to renew them. The wheels may be furnished with one, two or three rows of plugs, as desired.

Besides the special construction of the wheel itself, an automatic extension is provided for each of the rear wheels, this being designed for use when the fields are exceptionally soft or the roads are very muddy. Each consists of two wrought iron bars between which are heavy cast lugs eight inches in width. These lugs are mounted on pivots and the points are held below the surface of the wood plugs by means of springs. When the wheels travel over muddy roads or soft ground and sink so that the points of the lugs touch the ground, the revolution of the wheels causes the lugs to be extended vertically, 4.5 inches beyond the periphery of the wheel itself, forming a solid bearing surface against which to push. They are drawn back by the springs and return to their original position when not needed. It will be seen that their action is entirely automatic, coming into play the moment they are required and slipping back out of the way when their work has been accomplished. For such work as plowing or harrowing the lugs can be fastened permanently in an extended position if desired.

Plowing, Discing and Harrowing.

Accompanying illustrations present the Avery farm truck at work on so-called small farms, and indicate some of the many uses to which they may be put. Other instances will be cited, and while it is impossible to give a detailed comparison between the cost of these vehicles and that of horses, for the reason that farmers have not been given to keeping accurate account of such matters, it can be shown that one such truck will do the work of from six to 10 horses without difficulty and at a decided saving in expense.

One very pronounced difficulty comes to mind readily when considering the use of a truck of this nature in plowing. An accompanying illustration shows William Larson hauling three plows behind his Avery, and he says he can plow 10 acres a day, working on short land about 80 rods long. He adds that the truck keeps a straight furrow without being steered, and that the expense of plowing is confined to approximately two gallons of gasoline an acre.

Discing and Harrowing at the Same Time with Avery Farm Truck on Miller Bros.' Farm in Bliss, Okla.

But, granted that it is an easy matter to make the truck keep a straight furrow, how about the turns at the end of each furrow? Clayton Spratt of Auburn, N. D., plowed 150 acres with four 14-inch bottoms on old ground, averaging 11 or 12 acres a day with a fuel consumption of about two gallons to the acre. He also tried this equipment on some fresh sod, just to see if it would accomplish the work. The 150 acres were plowed on land of 25 acres, plowing six rounds and taking the plows out of the ground at the ends, after which they were not lifted again, as the machine was driven around the ends.

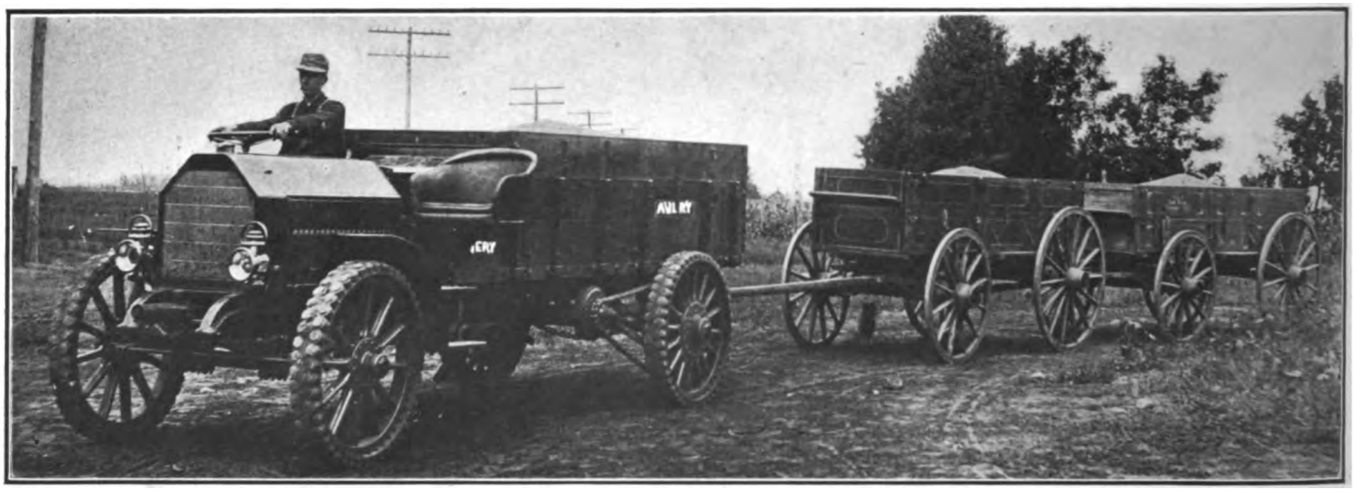
Miller Bros. of Bliss, Okla., estimates that its truck will do the work of eight horses in plowing, discing and harrowing. The machine shown herewith pulled three 14-inch bottoms with a harrow attached behind, and worked at the rate of an acre an hour. The photograph depicts it hauling two disc harrows with 14 discs to a harrow, and two drags, a load which would have required eight horses

Digitized by Google

to draw. After the ground was prepared, the truck pulled two 12-hole disc drills, drilling in the seed, a work which it is claimed would have been heavy for 10 horses.

An All Around Machine.

Apparently, Harvey Shippy of Chapman, Kan., found one piece of work which he could not do to advantage with the truck, that of plowing or cultivating corn. He employed four horses for this job, doubtless because he has not yet found a way to run the vehicle over the rows without crushing the tops. However, it did all the rest of the work on his 400-acre farm, including plowing, discing and harrowing, 130 acres of which was cared for in the fall, cutting 125 acres of wheat, running a four-roll shredder, shredding corn, hauling sand, grading eight miles of road, in the last named work getting close up to the hedges where it was impossible to go with horses. The expense for the year was limited to oil and gasoline and one set of little boxes. The fuel bill totaled $99, which he says is ever so much cheaper than hay and feed.



In the chassis view, herewith, the pulley at the front is for the purpose of attaching a belt for use as a power machine of all sorts. J. F. Sweany of Stafford, Kan., shelled 800 bushels of corn with the truck shown in an accompanying illustration, without stopping and with a trial start at that. He says he had enough power to operate the six-hole sheller and plenty of reserve.

After plowing with three 14-inch bottoms in a field of 80 acres against three three-horse teams, each pulling a 16-inch plow, in which work he turned over 50 acres while the horses were turning over 30, and using his machine for all sorts of work throughout the summer, J. A. Waltner of Freeman, S. D., loaded the truck and two horse wagons as trailers with 198 bushels of wheat. The camera caught him on the way to market, on which trip he drove at the rate of six miles in 57 minutes. Using these same two wagons in the same manner, he carted seven tons of hay to the baler at a trip. After baling the hay, he put 70 bales on the truck, loaded the two wagons with 4.5 tons more and hauled this load a distance of 20 miles, most of the journey on the high gear. He says he finds the machine more convenient to handle around the farm than horses, particularly as it is ready to go at an instant's notice.

Ashton Rollins of Three Rivers Farm, Dover, N. H., uses his Avery truck to haul lumber, potatoes, apples, etc. During the late summer and fall he cut silage and run a small saw mill, taking day work among the neighbors. He also did all the plowing and harrowing on his farm.

E. W. Parsons of Jennings, Kan., says he can do the work of three four-horse teams with an additional saving of at least one man. His work is principally that of covering an oil route, averaging eight trips in six days, five of them of 40 miles, one of 32 and two of 20. The average expense of the 40-mile trip for oil and gasoline is $1.40.

Thus is presented the argument for the Avery farm truck. It is an all around power machine. It will haul loads on its own body as well as in trailers. It will do the plowing and field work, and all kinds of belt work. It will do the work of from six to 10 horses, and it costs less for gasoline to run it than to feed the horses necessary to do the same work. It saves money besides being easier to take care of and handle. It saves the expense of keeping surplus horses for use only in rush seasons. It doesn't eat anything when not at work. It requires one-tenth of the storage space necessary for horses and the hay, corn and oats they must eat. It is possible to do the work when it should be done regardless of weather conditions. It makes for larger crops by doing the work right. It will haul a load in from one-third to one-half the time required by horses, and even faster if necessary. It will work as many hours as needed, and when the work is done it is simply backed into the shed, the switch is turned off and the labor is ended. It doesn't have to be cared for at regular hours on Sundays and holidays. It is ready for work instantly. It is possible to start right in at work the first thing in the spring, without waiting to get seasoned. It is easier to handle, and backs up quicker and just where it is desired to go.

J. A. Waltner of Freeman, S. D., Hauling 198 Bushels of Wheat to Market with Avery Farm Truck and Two Horse Wagons as Trailers.

SCIENTIFIC HAULAGE COSTS.

More and more firms are beginning to appreciate the need for scientific analysis of their haulage costs, an indication of which may be seen in the fact that the American Locomotive Company's transportation cost bureau was recently called upon for such analysis by 102 large concerns in 37 different industries.

WOMEN TAXI DRIVERS.

Taxicab operators who have been troubled with dishonesty and inefficiency among their drivers will no doubt watch with interest the experiment of a Chicago taxicab company, which has hired 20 women as chauffeurs. The company expects that the new recruits will be more honest, careful and respectful to patrons. While the change is so far only an experiment, abroad women taxi drivers have been thoroughly successful, Paris having found them to be as good as the men, and better in some respects.

UNITED STATES ARMY FIELD WAGONS.

SOME little surprise will no doubt be occasioned by the statement that the government has taken steps to obtain from commercial car manufacturers reports of the sale of each machine, with the address of the purchaser and the size and power of the vehicle. An impression exists that this country is far behind the European powers in its preparation for utilizing motor trucks in military operations, but according to Capt. Alexander E. Williams, 19th Infantry, U. S. A., writing in the Infantry Journal, the United States has gone further than any foreign country in its experiments with automobile transportation for the army.

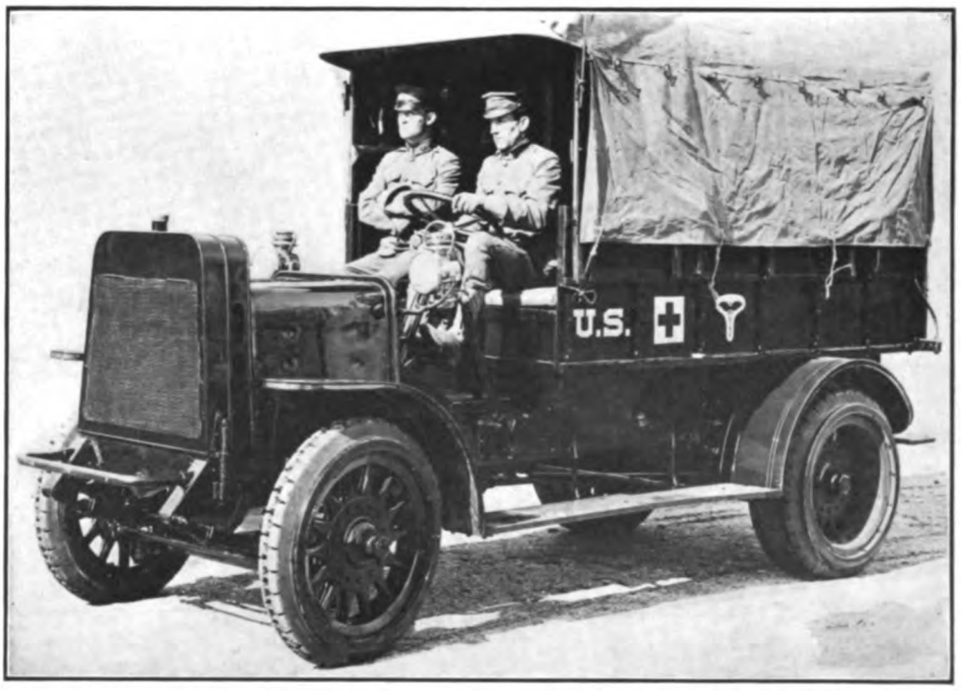
A large number of experiments has been made in all parts of the country, employing trucks under all conditions and for many various uses. Details of these have naturally been kept somewhat private, and comparatively few particulars have reached the public, with the exception of where purchases by the government are used as a basis for advertisement by the manufacturers. Besides the information obtained in these tests, the War Department has detailed information of the number of trucks being manufactured and sold in this country, with the mechanical features of the various makes. All this data, coupled with the records of the sales of machines, will give the government definite information for use in case of war, and will prove invaluable. Besides being able to select the machines best suited for war purposes, the sales records will show the capacity of each factory, enabling emergency rush orders to be placed where they will be filled quickest.

That no misapprehension as to the field of the motor truck exists in the War Department is made clear by Capt. Williams' article. The service for which they are desired is to transport supplies from what is called the rail head, the terminus of the railroad nearest the field of operations, to the field. It is not expected that the trucks can go across country to the actual camps, which may be far from a road. For this work, the regular mule transport system will be used, taking the supplies from the trucks on the nearest road.

Developing Field Truck.

The government hopes, however, to secure a machine that can take the place of the escort wagon and mules as a means of transportation for the troops in the field. This is seen in the fact that after considerable study of the situation, two special machines are being built to the War Department's specifications, one with chain drive and the other shaft driven. They will be of one and 1.5 tons capacity, respectively, and will be thoroughly tried out in all the work that a field wagon is called upon to perform. No details of the machines have been given out, but they will probably be light, with high wheels affording a big road clearance. While the road trucks will each replace several mule teams, it is not expected of the new field trucks that they will perform more than the work of one mule wagon.

Capt. Williams gives some very interesting figures comparing the costs of motor and mule transportation, showing the motor equipment would cost for fuel less than half what the mule would eat in oats and hay, and that the motors would take up on the road 22,596 feet, or over four miles, less than the mule train—a valuable consideration when trains have to be convoyed by troops in passing through a hostile country. The figures follow:



Forage for 3268 Mules for One Month:

	Weight, pounds	Space occupied, cubic feet	Cost
Oats	882,360	32,188	$14,770.70
Hay	1,172,560	114,380	10,170.67
Totals	2,054,920	146,508	$24,941.37

Gasoline for 807 Trucks for One Month:

Gallons	96,840	623,420	19,368	$12,105.00

Besides the saving of $12,836.37 presented here, there is a difference in weight of 1,431,500 pounds in favor of the fuel for the motors, and a saving in space of 127,200 cubic feet. It may thus be seen that the bulk of the gasoline would be less than one-seventh of that of the forage, which would mean, beside the saving in the cost of transportation, a great economy in the space required for storage at depots, an exceedingly valuable consideration in time of active operations. Also, the gasoline tanks on the trucks take no space from the loading platform, while the forage for the mule teams requires considerable room on the wagons.

Main Army Field Wagon Which Took Part in the Recent Test Run from Washington to Fort Benjamin Harrison, Indiana.

In an Emergency.

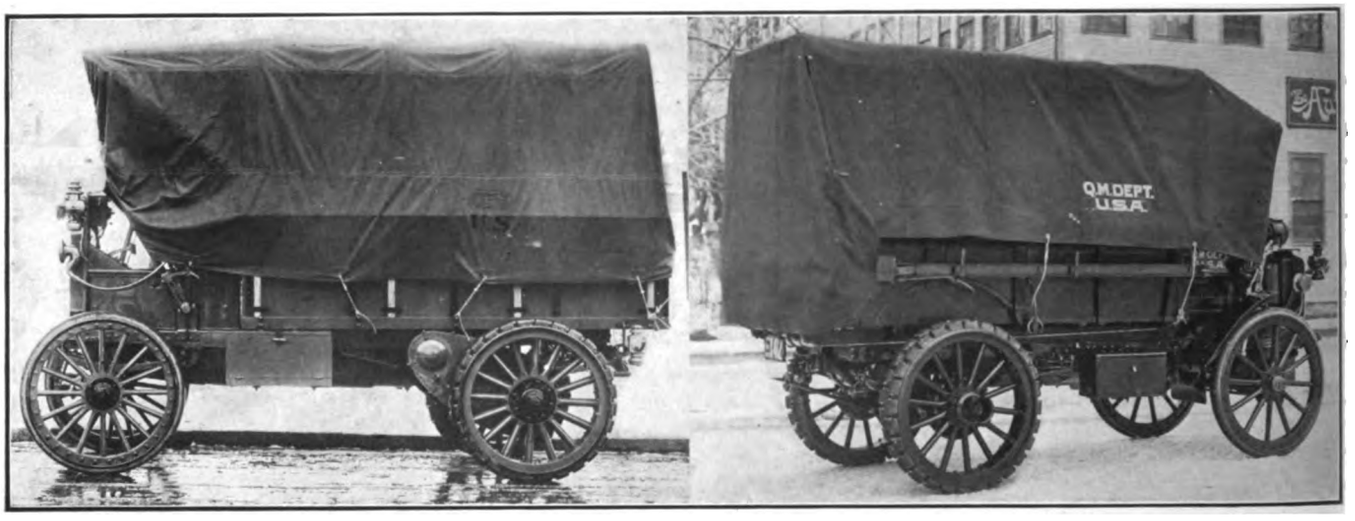
It is not contemplated that the government shall purchase a large number of trucks and hold them till war time, but a subsidy of privately owned machines of approved types is recommended. In case the new vehicles prove a success, somewhat of a problem is presented in the matter of rendering a supply available in time of war. It has been suggested that this military type of truck would be but little unsuited to use by private concerns, and that a substantial subsidy would induce purchases for business use and give the government a large fleet of machines from which to draw in an emergency. If there were no large

Digitized by Google

privately owned fleet of machines available to the government, the only alternative would be to accumulate and store in various parts of the country a sufficient number of trucks to meet the requirements of an emergency. This would be much more expensive than a subsidy.

Either method appears expensive, but one or the other must be employed unless the government wishes to trust itself to the rather uncertain chance of acquiring machines of more or less suitability on short notice. In the past, the War Department has purchased mules immediately on the outbreak of hostilities, and has had little delay in fitting out the road trains, but if motors of a particular style must be depended upon, considerable difficulty will be experienced unless some provision be made, through subsidy, or otherwise, to secure machines in advance.

Of the two methods, the subsidy presents the more advantages. If the trucks were to be bought, when of no further use at the end of the war, they would have to be returned to the storage depots. But if secured under the subsidy scheme, at the end of the war the trucks would have a ready sale, and would realize their actual value, or could be returned to their original owners at a suitable price.



Just how far this country is ahead of European powers in the matter of motor truck transportation for the army may be seen in the statement of Capt. Williams that while the foreign countries have trucks for road use as here, they have not made any plans to develop a machine suitable for field use, and do not expect that any such machine will ever appear. This country not only has made plans, but has designed and is having built a machine which it is hoped will prove suitable for field service; if it does not, another attempt will be made.

This is quite in contrast to the view in England. In an article on the subject, Col. Paul, assistant director of transportation, British Army, stated that no mechanical vehicle exists at present which is trustworthy for supply train work, in distributing supplies over every kind of country off the roads, and that no suitable vehicle is to be expected in the near future. While the United States War Department agrees with Col. Paul on the first count, that there is no truck at present suitable for field work, it does not agree on the second, and is actively at work trying to develop a machine that will enable the supply train to be motorized. The government expects to take supplies from the rail head to the advance depot by ordinary trucks working over the roads, and from the advance depots to the troops in the field by means of specially designed machines capable of traversing almost any country.

While the recent road test conducted by the quartermaster department of the United States Army was concluded about April 1, no definite announcement has been made concerning the results obtained. The event was in the nature of a competitive run of 1509 miles, starting in Washington, D. C., thence to Atlanta, Ga., and through the South, and ending in Fort Benjamin Harrison, Ind. Five cars were entered as follows: Autocar, Autocar Company, Ardmore, Penn.; Four Wheel Drive, Four Wheel Drive Auto Company, Clintonville, Wis.; Mais, Mais Motor Truck Company, Indianapolis, Ind.; Sampson, Alden Sampson Manufacturing Company, Detroit, and White, White Company, Cleveland, O.

If it were the intention of the government to set a task almost impossible of accomplishement it succeeded remarkably well. The route, for nearly 1400 miles, led over roads deep with mud and filled with washouts after a severe winter, and in many of the mountainous sections wagon traffic had been abandoned, since horses and mules had been shot after breaking their legs in trying to extricate themselves from the quagmires. It was in every way the most strenuous test to which motor trucks have been subjected in this country. The complete details will be awaited with interest.

The vehicles were equipped as regulation army wagons, as the accompanying illustrations bring forth. Each was manned by a driver who thoroughly understood its construction, and a United States soldier, who watched its action throughout the run. These soldiers reported their findings to Capt. H. A. Hegeman, quartermaster department, Fort Benjamin Harrison, who will make known the result after its submission to his superiors.

Two of the Vehicles Which Completed the Recent Army Road Test: At Left, Sampson 1,5-Ton Truck; at Right, Autocar of Same Capacity.

Condition of the Roads.

The roads were in even worse condition than the army officials anticipated. From Washington to Richmond, Va., and until the North Carolina line was reached they were not difficult, despite the rough and ice covered spots. But once in North Carolina, it was all the cars could do to make headway at times. It was a frequent occurrence for a truck to drop into a hole up to the body, when it would be necessary to spend hours with block and tackle getting it out.

In many places the mountain roads were so steep and so coated with ice that it became necessary to spread branches of trees over the ground and chop a series of steps in the ice to facilitate traction. Near Jeffersonville, Ky., a stretch of mud was encountered which proved too deep for any of the trucks to navigate under their own power, and all were forced to utilize block and tackle applied to the telegraph poles, in order to extricate themselves.

KISSELKAR TRANSPORTS ICE.

In transporting ice in warm climates it is essential that no time be lost in the hauling because of the possibility of shrinkage. The commercial vehicle is particularly adapted to this work, inasmuch as large quantities may be handled easily and hauled long distances in a very short time. The Kane & Trainor Ice Company, Stockton, Cal., a large dealer in this commodity, is utilizing the mechanical transport with success and in the accompanying illustration is depicted a truck fitted with a special body for the purpose of hauling ice.

The vehicle is the product of the Kissel Motor Car Company, Hartford, Wis., and is propelled by a four-cylinder, four-cycle, water-cooled motor. The clutch is a large cone of the adjustable type and power is transmitted through a selective type of sliding gear transmission, affording four speeds forward and reverse with direct drive upon third. Final drive is by side chains of ample dimensions. A feature of the rear system is the fitting of a differential lock, a device whereby the driving axles may be locked as one member, thereby facilitating traction when one rear wheel is in mud or on slippery ground. It also provides for an emergency drive in the event of a chain breaking, as the car could be propelled by the remaining member. The Kane & Trainor Ice Company is very much pleased with the truck, it having demonstrated its value, economy and power in the transportation of ice.

KisselKar Truck in Service with the Kane & Trainor Ice Company, Large Dealers in This Commodity at Stockton, Cal.

LYNN BUYS FOURTH TRUCK.

The city of Lynn recently took possession of its fourth municipal truck, this being a one-ton vehicle for the use of the street department. The commissioners are still considering the bids submitted for the police and fire department wagons, which were opened recently. The next purchase of this nature will be a vehicle for the use of the health department.

PELLETIER WITH UNIVERSAL.

In addition to his other duties as advertising director of the Studebaker Corporation and advertising manager of the Flanders Manufacturing Company, E. LeRoy Pelletier, well known in the industry, has joined the advertising staff of the Universal Motor Truck Company of Detroit. It will be remembered that W. E. Flanders, president of the E-M-F Company, now a constituent of the Studebaker Corporation, recently acquired an interest in the Universal company.

BRUSH AS VACUUM CLEANER.

A vacuum cleaner company in Indianapolis, Ind., recently equipped a Brush runabout, made by the Brush Runabout Company, Detroit, with some of its machinery for cleaning houses, etc., connecting the shaft to the regular driving shaft of the car by shifting the chains. As a result the automobile is utilized in hauling the cleaner to the scene of operations and takes the workmen along with it.

This Brush car has been working in this manner every day for a period of five months, during a greater portion of which time the working hours have been as high as 14 and 15 a day. No replacements have been found necessary and the owner considers that the test has been much more severe than would have been the case in ordinary driving over the roads.

Since noting the success the concern has had with this vacuum cleaning outfit, several other cleaning companies are planning to utilize cars in the same manner.

MOTZ TIRE EFFICIENCY.

The Motz Tire & Rubber Company, Akron, O., maker of Motz cushion and solid tires, is calling attention to its product and its effect upon the commercial vehicle industry in a neat little booklet of 24 pages, which will be sent free upon application. It is pointed out that when the tire expense is considered it will be found that the wheel equipment is one of the most important features in connection with the operation of a mechanical transport. The booklet sets forth numerous ways of bringing about tire efficiency and thereby reducing materially the cost of maintenance. It is fully illustrated and will prove a valuable treatise for those who are troubled with tire problems.

D. R. Linsley, formerly with the Pierce-Arrow Motor Car Company, Buffalo, N. Y., has joined the sales force of the Chase Motor Truck Company, Syracuse, N. Y., and will make his headquarters in the latter city.

PUBLISHED THE FIRST OF EACH MONTH.

SUBSCRIPTIONS:
The United States and Mexico, the year, $1 in advance; Canada and Foreign Countries in Postal Union, the year, $2 in advance. Fifteen cents the copy.

ADVERTISING RATES:
Information given on request. All advertising copy must reach this office not later than the 25th of the month preceding.
Anonymous communications not considered. Correspondence on subjects relating to trucks, delivery wagons, taxicabs, tractors, all motor driven farm, fire, and municipal apparatus, the motor industry and the trade, will receive attention. Stamps must be enclosed to insure return of unsolicited contributions.
Entered as second class matter, February 25, 1911, at the Postoffice at Pawtucket, R. I., under the Act of March 3rd, 1879.

TAXING THE MOTOR TRUCK.

Automobile owners have submitted so long to the proposition of taxing their property for the cost of highway construction and maintenance, in which the entire public benefits, that perhaps it is not surprising that there should be effort to increase revenue by including the motor truck. However, there is a hopeful sign in the decision of certain motorists in Jackson, Mich., to test the constitutionality of the new law in that state. It also will be remembered that the New York State Automobile Association threatened to take the matter into the courts if the legislature persisted in its desire to enact more radical legislation on this subject there.

Massachusetts is setting a bad example with its latest bill to tax all automobiles, whether pleasure cars or trucks, on the horsepower basis. The industrial transport is a business proposition, and business men who may submit to conditions which concern their social life are prone to look upon matters which affect their business in a very different light. It may be that pressing the proposition too far will result in the discovery that the whole plan of taxing motor vehicles in this manner is class legislation, as many have suspected.

Chairman Charles Thaddeus Terry of the American Automobile Association has expressed the situation in the statement that motorists have submitted to this form of legislation only because of their interest in good roads. There is bound to come a time when they will no longer submit, particularly when the true economic value of the modern method of transportation is better understood and appreciated.

BUSINESS VALUE OF PARADES.

The second annual motor truck parade in New York City this month brought out an increase of nearly 100 per cent. in the number of vehicles in line. To those who have direct interest in the production and sales of industrial transports this has important significance, and the business man who carefully analyzes the situation will find much food for thought in this demonstration.

The day is gone by when concerns were purchasing and using commercial vehicles because of their advertising value. Every truck in service today represents a factor for economy and efficiency. Of course, by no means all the installations in the metropolis were represented, but undoubtedly the increase in number of vehicles on parade is a fair indication of the increased number in use.

This brings up the suggestion that there is decided value in these demonstrations; quite as much, if not more than in some form of competition. Other cities will follow the example of New York in holding similar parades throughout the year, and the practise should be extended even to the municipalities of the minor class. While these vehicles are in daily operation on the city streets, some organized attempt to call the attention of the business public to them will create a decided impression and set other business men to considering the possibilities for motor haulage for their individual needs.

THE LIGHT DELIVERY WAGON.

While the manufacturers of commercial vehicles have been seeking to develop a demand for their product with certain lines which require heavy duty machines, perhaps there has been a lack of interest in the small business, the needs of which are confined to the light delivery car. That there has been some appreciation of the possibilities along this line is evidenced by the number of such wagons which have made their appearance of late. Still, there is room for question as to whether or not sufficient attention has been paid to the requirements of the individual purchaser.

Special body designs are quite common, particularly with respect to the dumping wagons and so-called brewery trucks. There is quite as much reason for considering the small delivery business, however. It is conceded that a motor truck, no matter what its load carrying ability, develops its greatest efficiency only when worked to its capacity. Many small wagons could be utilized to advantage if it were possible to supply the carrying space so arranged as to provide for the exact requirements of the owner. This is a phase of the situation which is only just beginning to be given the attention it deserves, and there is much indication that it will receive careful thought and experimentation during the coming season.

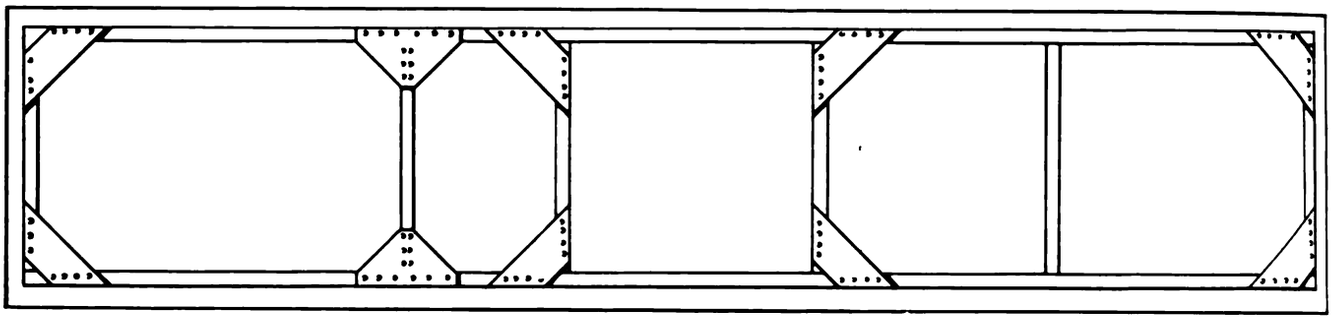
CHARACTERISTICS OF TRUCK DESIGN.

Developments in Construction That Have Eliminated Weaknesses and Made Possible More Uniformity of Strength and Greater Endurance of Chassis.

EVERY motor vehicle designer has sought to incorporate in his creations the desired elements of power and strength, and assumedly each man has satisfied himself that his conclusions are dependable, but with experience changes have been found desirable or necessary, often because of unexpected stresses and strains. No machine has been constructed that can be accepted as being absolutely without flaw. With some, faults will be more pronounced than with others, and when it is realized that the greatest strength of a construction is its weakest part there is the more need of studying every component and developing all so far as this may be done to a proportionate and harmonious whole.

This statement is made, not to condemn, but to justify changes and betterments in what may appear to be the unimportant details. In fact, there is nothing that is not necessary in a chassis, and from the smallest to the largest part each must be in correct relation to the other because all must endure, or should endure, the same length of time and under the most severe conditions of service. There is this fact to be considered in power wagons, that continuity of operation is imperative, and there can be no experiment made which will result in loss to the owner or reflect upon the maker. The mechanical transport is bought because it is tireless, and has speed and capacity that will save in time as compared with animals and minimize manual labor. Sentiment is out of place in business dealings and undoubted economy is the only logical reason for making investment. No man wants to take chances in business. He must be assured of improved delivery or haulage and insured against any possible delay. He cannot afford to make sacrifices. Once he is the victim of circumstances, not negligence or fault, he will lose confidence, and this reacts upon the maker of the vehicles that he owns or owned.

The designer of the power wagon has to deal with an entirely different proposition than the man who produces a pleasure car. He can take nothing for granted and he must know that what he has planned will work out in every detail with a certain margin of safety and endurance. The truck is often worked to an extreme by the driver or owner who believes that he is justified in loading beyond capacity, and driving to extreme speed, causing strains that are not possible with normal freights and operation. The responsibility for damage through overloading is generally shirked by the owner and driver, and pretense is made that the builder is at fault, because it is hoped that he will be either compelled or induced to assume the expense under a guarantee. There are limitations prescribed in every guaranty that are expected to protect the builder, just as the conditions afford protection to the owner, but the line of demarcation, if finely drawn, will often precipitate complications and perplexing situations.



Top View of Eckhard Chassis Back of the First Clutch, Showing the Very Large Transmission, the Second Clutch, Differential, Sub-Frame Suspension, the Long Torsion Bar and Torsion Chain, All of These Being Features of Construction.

The manufacturer of vehicles must give his customers satisfaction because of the competition and the future. He realizes that he must make a guarantee that is liberal, largely to create confidence in his machine, and when this has been established it is necessary for the designer, so far as he can do so, to protect the builder against this guarantee. This being so the chassis must be studied for weaknesses and each element carefully observed through varying conditions of service. It may be that one part of seeming insignificance will be the keystone of the entire structure. Every other component may be adequate, and yet all are insufficient because of the failure of the one. It is possible that with the improvement of this element an entirely different character of service may be obtained. It may be a matter of workmanship alone. But whatever the cause it is necessary that it be eliminated.

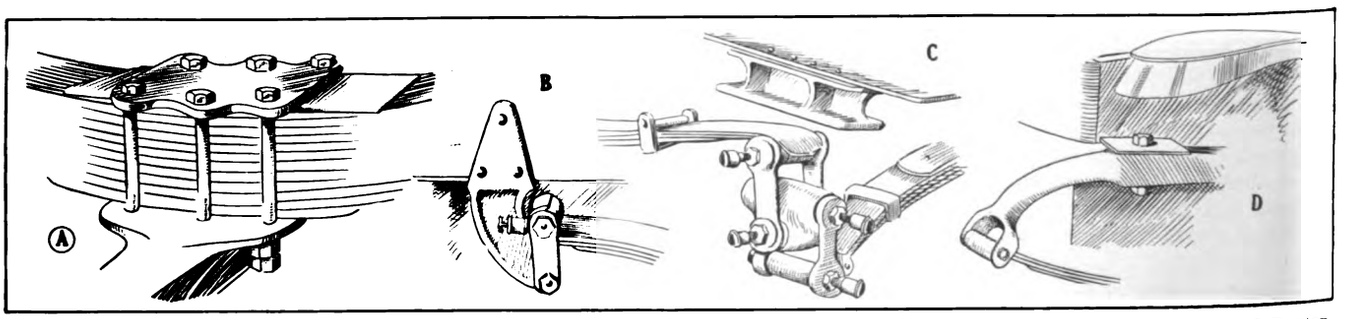
Frames and Springs.

In the motor vehicles there is no more important part than the chassis frame. With rare exceptions these are of metal and usually the material is steel. Wood is sometimes

Digitized by Google

Top View of Chassis Frame of Alco 6.5-Ton Truck Covered by the Body, Showing the Six Cross Members and the Reinforcement by the Large Gusset Plates.

employed and occasionally angle iron, but generally the members are channel section steel of differing grades, the form being determined to secure ample strength and the least weight. The members are formed of metal selected for its strength, which is often heat treated to insure this quality to the extreme. But with strength the next consideration is lightness, and while a frame may be strong the members may yield to varying strains. In the absence of temper that will resist distortion and conform to a certain shape the frame is expected to have a degree of elasticity that will protect it against stresses that might otherwise cause breakage. The frame members ought to be well assembled that there be no failure of the bolts and rivets, because wear will quickly develop at a rivet or bolt and the breaking of a single fastening will permit such excess distortion as to cause much damage to other members.

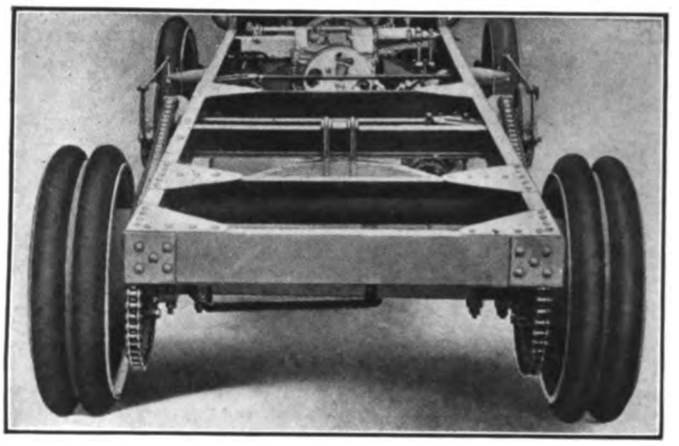


Every steel frame can be twisted. Complete rigidity would be ideal were it not impossible because of the great weight necessitated, and impractical because of the large proportion of power that would be required to propel it. The frame is supported by four or more springs that are assumed to protect it against excessive stresses and vibration, but the wheels always contact with the road surface and should one drop below the plane in which the others are moving the support of the frame by the spring carried by the wheel is lessened, and for a very brief interval there is an entirely different stress upon each member. This constantly changing condition of operation must eventually have effect upon the frame structure. The vibration results in metal fatigue, which is evidenced by breakage and can only be remedied by repair or restoration.

The frame is supported by the springs at either end and as the support of these is variable and as the shocks from road obstructions are transmitted through the springs, the greatest movement of the frame is at the ends and least at the centre. The most intense vibration is when the machine is driven unloaded, and the most stress is when driven loaded. As the motor is heavy and is carried forward it is often supported by a sub-frame attached to the chassis frame. The engine is expected to move with the chassis, but to avert leverage pressure upon the shaft universal joints are installed in the driving system. In several instances the power plant is made a unit and connection is to the cross members forward of the chassis centre. The drive is by shaft to the jackshaft located back of the centre, and by side chains. There are other forms of construction, but these are the exception.

Bracing the Assembly.

In the construction of the chassis frame the attention of designers has been directed toward bracing the assembly to minimize the twisting stresses and to secure so far as this may be practical a more general movement of the whole. The steel channel side members are connected by cross members of the same material. These are hot riveted in the best work and heavy gusset plates are used to brace the angles of the members against longitudinal or lateral movement. Theory would dictate that these gussets be proportioned to the frame, but that the same construction obtain with each. Opinions differ widely, however, and with the varying designs it will be noted that as a rule the number of gussets is increased with the size of the frame. This is especially noticeable with the Alco 6.5-ton chassis frame, in which every angle from the rear of the frame to the end of the platform space is braced. These gussets are usually placed at the top of the frame and seldom on the lower angles, there being evidently an assumption that sufficient strength is afforded with the single series of gussets. There is not, however, the same degree of rigidity that would be obtained with two sets of gussets. The example of the Alco is given as an illustration of advanced engineering with heavy trucks, and in connection with this is shown the manner of bracing the frame of the three-ton Pope-Hartford truck, in which the same practise is followed, but not as completely as with the larger Alco.



Few realize the driving stresses upon a truck frame because, under conditions usually obtaining, the drive is through the radius rods from the rear axle to the frame, and there is the influence of the thrust at either side, which cannot be equalized unless each wheel has the same traction and the differential is locked. With the radius rods fast to the axles there is resistance by the rods to the turning movement of the axles when the wheel brake is used, which lessens the strain upon the springs, but there is decided influence upon the frame because of the rods and the drag of the chains on the transmission unless the clutch be disengaged.

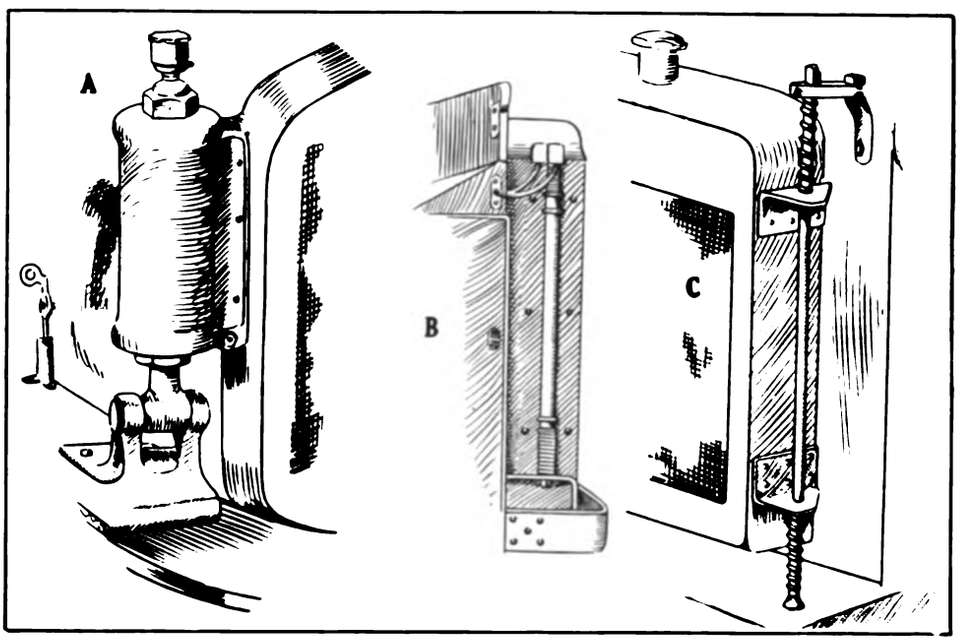
Some Examples of Spring Installation: A, Grabowsky Rear Spring Anchorage; B, Forward Hanger and Shackle of Dayton Rear Spring Construction; C, Barrel Shackles and Buffer of Grabowsky Platform Spring; D, Short, Heavy Spring Horn of Victor Truck.

Digitized by Google

In the event of wear of the radius rods or their connections the stresses are partly taken by the springs, which are not constructed for such work, and the result is not

The Strongly Braced Load-Carrying Section of the Pope-Hartford Three-Ton Truck Chassis.

only destructive of the springs, their bolts, shackles, clips and hangers, but affects the chassis frame. The drive influence differs with the manner of loading. When a frame has sagged and been set out of line it will be understood that every other element is affected, provided that they are connected with the members. This applies to the levers and connections attached to the frame, to the shaft alignment, to the transmission, the jackshaft and its hangers, and to the radius rods and brakes, because there is lessened and excess movement as compared with the normal action.

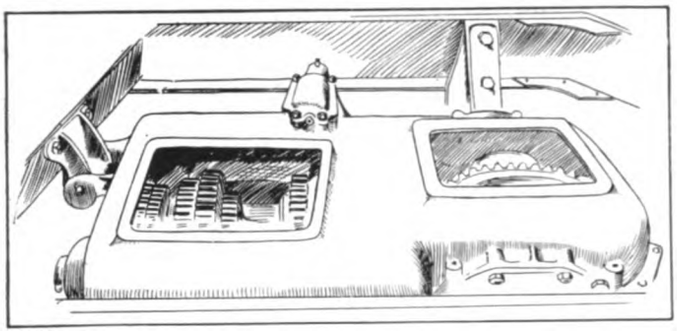


The frame, because of the reasons stated, is the keystone of the entire structure, and if it does not at all times maintain the elements of the truck in precise relation there is a certainty of abnormal wear and, perhaps, rapid deterioration. In the Eckhard chassis the designer has not only used conventional construction so far as the radius rods and springs are concerned, but he has provided a torsion rod that is connected with the front and rear axles and fitted with heavy spring buffers that relieve the radius rods of the upward forward thrust and applies a horizontal forward thrust from the rear axle to the front axle. This also lessens the strain on the forward springs and permits a more normal suspension by carrying the drive to the forward wheels and distributing the road shock stresses throughout to the heavy rear construction. This is an adaptation of the wagon perch for the maintenance of distance between wheels to the needs of the motor wagon. It is said that this works out exceedingly well in practise.

To minimize turning stress upon rear axle when wheel brakes are used, and good judgment would dictate that their use will nullify any strain upon the transmission, a torsion chain is employed. This is attached to the rear frame cross member and carried to a hook on the end of a vertical arm at the centre of the axle, and beyond a moderate stress upon the springs the chains restrains the twist of the axle.

The strain upon the rear spring saddles is at times extreme, and it often results in broken spring clips and a disabled machine. In the Grabowsky truck the spring clip has been eliminated and in its place is used a plate practically the same size as the saddle. This is drilled for six bolts, and two of these pass through the axle and the other four through the saddle, so that when all are tightened the spring is held much more solidly than with the ordinary clip. Should a bolt break it can be replaced without difculty, while a broken clip cannot always be readily obtained. The substantial work and the simplicity of construction are in every way commendable, and the increased strength is much to be desired.

With a majority of the designers the purpose is to protect the springs against wear and to accomplish this a longer member is used because of the lessening of the number of vibrations with increased length, and the decreased movement of the spring at the eye. Bronze eye bushings are the rule rather than the exception because of the longer wear with steel bolts than with the same metal contacting. And the value of lubricity at these bushings has led very generally to the use of grease cups. With all designs that which is simplest is best, and an example of both the practical and substantial is to be found in the forward hanger and shackle of the Dayton rear suspension. This is a steel drop forging of bracket type that is fitted under the frame member and is riveted to the side. The linkage is very simple and is easy to replace should there be wear or breakage. There is a very wide play for the spring.



The construction of the Grabowsky platform spring is worthy of notice because of the linkage, which minimizes the wear upon the spring eyes and insures freedom of the spring action, together with a certainty of complete lubrication of every bolt and bushing, this making for long endurance. Each bearing part is fitted with a grease cup and this makes certain that there will be sufficient lubricity with minimum attention. Fitted to the under web of the frame side member is a metal pad that contacts with the side spring end when the truck is loaded. The weight of the frame and its equipment is normally carried on the lighter cross spring, but the load is always supported and steadied by the side springs, the end spring being constantly compressed to the point where the side springs take the full load. This is held to give the same results as with the use of the side springs and an auxiliary or jack spring. All

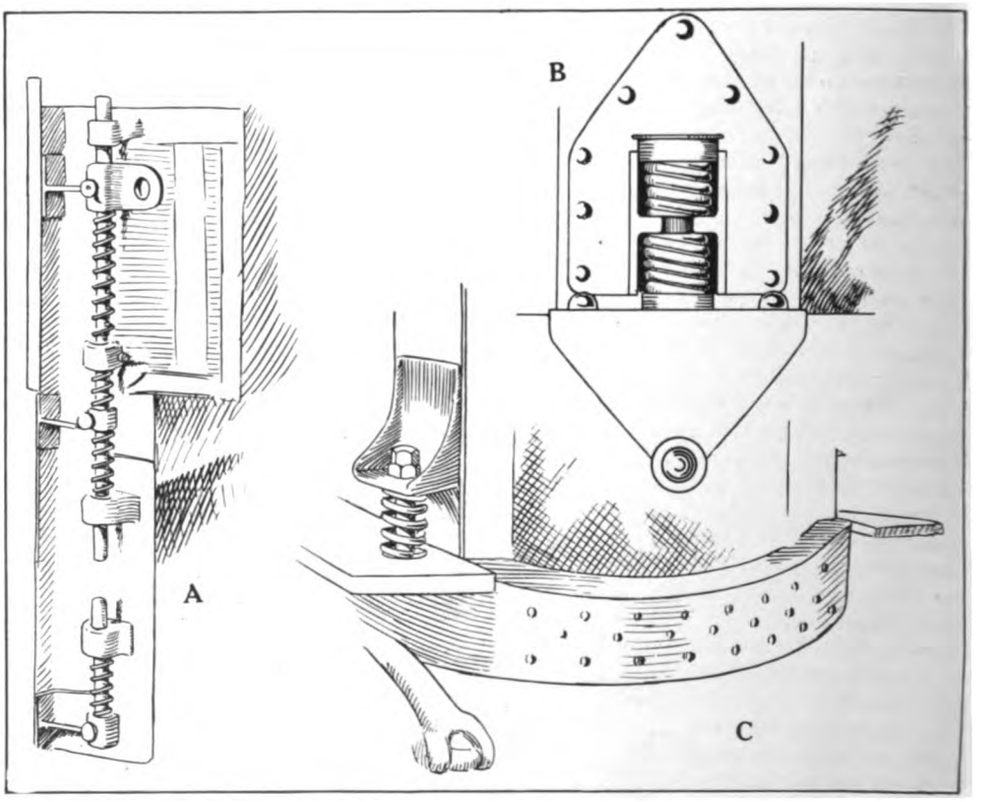
Digitized by Google

the Grabowsky spring eyes are steel bushed. To make certain of the full clearance necessary with the springs without using a sharply curved member that would necessarily have excessive action, and to carry the front axle sufficiently forward to perch the springs on centre, some designers have used short and well curved horns that are integral with the chassis frame side members. It has been found where the springs are attached to the chassis frame end that this, with some designs, brings the wheels well back, a condition not conducive to easy handling because of the inability of the driver to see the wheels when seated above the motor.

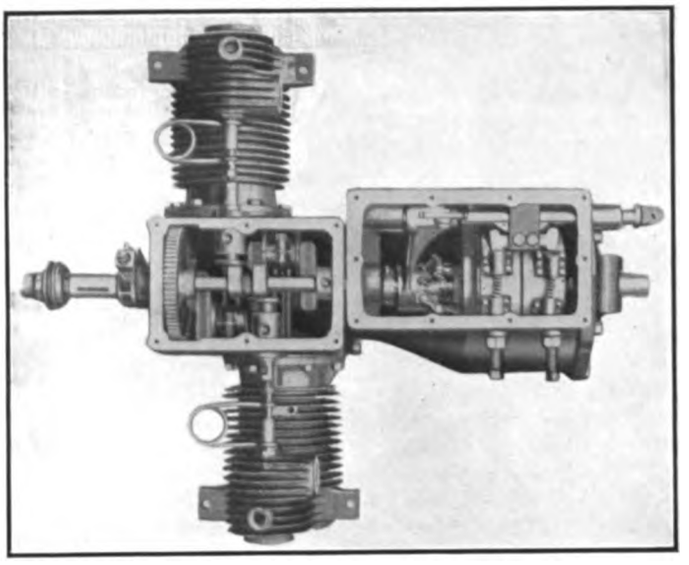


The Combined Transmission Case and Differential and Jackshaft Housing of the Locomobile Five-Ton Truck.

Transmission Design.

Realizing the stresses incidental to load carrying, designers have endeavored to guard against transmission failure by heavy constructions in the trucks of large capacity. In the Eckhard transmission the gearset is a separate assembly of such proportions as to cause surprise with those who observe it, for the shafts are seemingly enormous and the gears are proportionate in diameter and in face width. There is no question that they have unusual endurance and would probably withstand every strain that might be imposed. But to further insure against possibility of damage when changing gears there is a second cone clutch between the transmission and the differential, which is disengaged with the clutch between the engine and the transmission, and a brake applied brings the gearset to a full stop before the ratio desired can be engaged. The gear teeth are coned so as to make possible engagement when the gears are idle and to minimize wear. If the clutch be disengaged and the machine moving, the gearset is stopped instantly when desired and every possibility of damage to the transmission is eliminated. The shaft bearings of the gearset are large and should endure under every possible condition of use. The transmission case is suspended at the front end by links at the ends of the arms of a broad yoke pivoted on the heavy cross member of the sub-frame, and is carried at the rear on a sub-frame cross member, so that, with the universal joint in the clutch shaft ahead of the transmission, there is small probability of misalignment of the driving system.

The Locomobile transmission case is in combination with the differential housing and is a unit of unusual size. It appears to occupy a great deal of the space in the chassis frame and have weight that would seem unnecessary, but while it is a gearset that might be expected in a machine of much greater capacity examination of the gears and shafts shows that these should endure as long as any element of the truck. The case is bronze and very strong. It has two openings, one over the gearset and the other above the differential. The transmission shaft and countershaft are side by side and the gears and their condition can be determined almost at a glance. The differential is a continuation of the case and at either side is bolted the steel housings for the jackshafts, these containing the roller bearings close to the differential and the annular ball bearings at the outer ends. The housing of the jackshaft is mounted on spherical bearings in cast steel brackets attached to the frame side members, so that the alignment of the jackshaft is not affected by the distortions of the frame, and the forward end of the transmission case is suspended by a bolt that passes through a yoke on the frame cross member and a lug at the end of the transmission case. The bottom of the transmission case is of aluminum and this may be removed, in much the same manner as the bottom of an engine case, for work on the shafts, bearings and gears.



The case and the driving assembly need not be affected in any manner by the weight of a load or road shock and there is as near a three point suspension of the gearset and jackshaft as may be found in any form of construction, there being a larger degree of vertical movement possible than would ever be necessary in so short a section of the chassis, and there is a reasonable degree of motion permitted by the jackshaft mounting. The upper section of transmission case carries the gearset and by dropping the lower part the clutch pinion, countershaft or main shaft may be removed without disturbing any other components, these all being attached to the case by collars. This transmission has four forward speeds and reverse, and the gears are with 1.5-inch face, of heat treated alloy steel, and cut

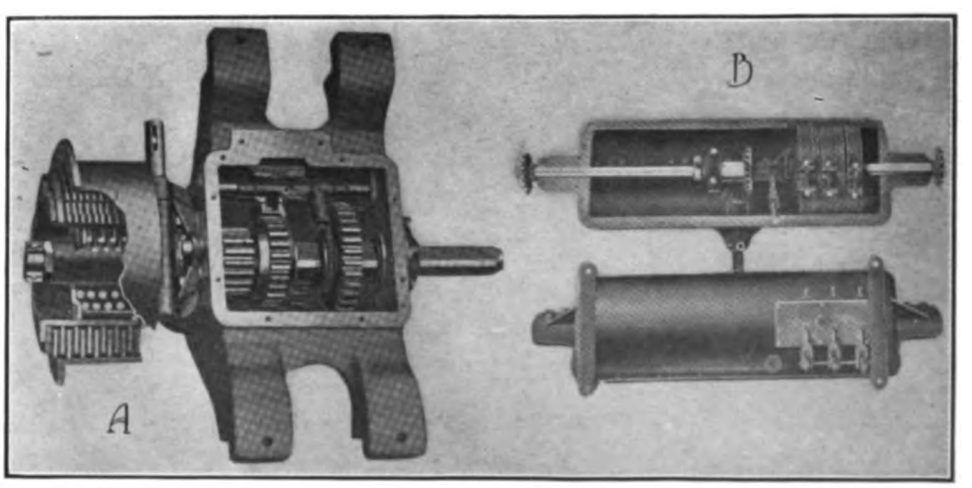
on a gear shaper to insure an accuracy that will minimize frictional losses. The countershaft gears are bolted to the faces of flanges, cut from the solid metal forming the shaft.



The Unit Power Plant of the Mercury Delivery Wagon, an Opposed Cylinder Engine and Planetary Gearset.

With the Grabowsky design the transmission and the clutch are practically one assembly, the clutch being a dry multiple disc creation with seven driving and six driven discs. There is no universal joint between the two and the clutch is carried between the rear bearing of the engine and the forward bearing of the transmission. A sliding transverse bar operates the clutch, the thrust being taken by the thrust bearing ahead of the forward transmission bearing. With this transmission the countershaft is below the main transmission shaft. The assembly is exceedingly simple and the construction is such that the gearset ought to endure under the heaviest service for an indefinite period.

In the Mercury delivery wagon the motor and the transmission are in two housings and one assembly, the transmission case being bolted to the engine casing. Because of the offset of the cylinders and the shape of the transmission housing the unit appears irregular in form. By the removal of two cover plates the interiors of the casings may be examined or work performed, there seldom being occasion to remove a part because of the extreme accessibility. This transmission is a planetary type with two forward speeds and reverse, the shaft being carried on heavy bearings. Simplicity and endurance are two of the qualities claimed for this construction.

Another transmission of unusual design is that installed in the Koehler delivery wagon, the case being of the barrel type with very long end bearings for the shaft. The shaft is mounted on a third bearing at the centre of the case. The transmission takes the place of the customary jackshaft assembly and within the housing at the left is the planetary gearset which has two forward speeds and reverse. The clutch is a cone in which the metal surfaces are operated in a bath of oil. The gears are of chrome nickel steel and the steel shafts, hardened and ground, are mounted in phosphor bronze bearings of great length in semi-steel casings. The transmission bands are extra width and are of semi-steel. The jackshaft and transmission case is so mounted in the chassis frame that the long bearings take the full load without side pressure leverage on the shafts.

Transmission Constructions: A, the Multiple Disc Clutch and the Substantial Gearset of the Grabowsky Truck; B, the Combination Transmission Case and Jackshaft Housing of the Koehler Delivery Wagon.

Radiator Mounting.

With practically all motor wagons of good design the radiators are installed upon springs that are intended to absorb the strains from chassis distortion and to eliminate the vibration that attacks the thin metal and eventually causes fracture. The connections with the motors are usually of rubber hose of large section and as the principal stress would come from the movement of the frame the designers have as a rule made provision for protection through suspension on springs. One of the most interesting is that used with the Sandusky machines in which the radiator is on springs carried on brackets and guides, and these in turn carry other brackets and guides supporting the gasoline tank.

The radiators of Victor trucks are built with a bracket at either side in which a hole receives a bolt anchored in the chassis frame, this bolt forming a guide for a short helical spring that resists all action. To prevent the heavy curved cross member of the frame in front of the radiator from reducing the radiation the member is perforated with three rows of holes. Into the reinforced sides of the radiator frames of the Federal trucks, and carried on stout steel rods, are two short helical springs of large diameter, separated by a substantial lug. This is neat and finished in appearance. The White truck radiators are carried on shock absorbers that are cylinders of large diameter enclosing helical springs above pistons, the lower ends of the piston or plunger rods being attached to bolts set transversely in brackets on the chassis frame. The radiator is so hung that it may be moved slightly in any direction without any stress whatever upon it.

The Pope-Hartford radiator suspension is with long rods fixed to the chassis frame on a bracket and to the radiator at the top, there being helical springs at the top and bottom of the rods with collars to retain the springs. This design relieves the radiator of strain and allows a slight transverse movement. Somewhat similar is the method of mounting the radiator of the Sanford delivery wagon, in which rods are anchored in the chassis frame and held by brackets on the dash at the top. At the top and bottom of the rods are coiled springs that are slightly compressed between brackets on the radiator frame and effectually resist distortional action of the chassis.

(To Be Continued.)

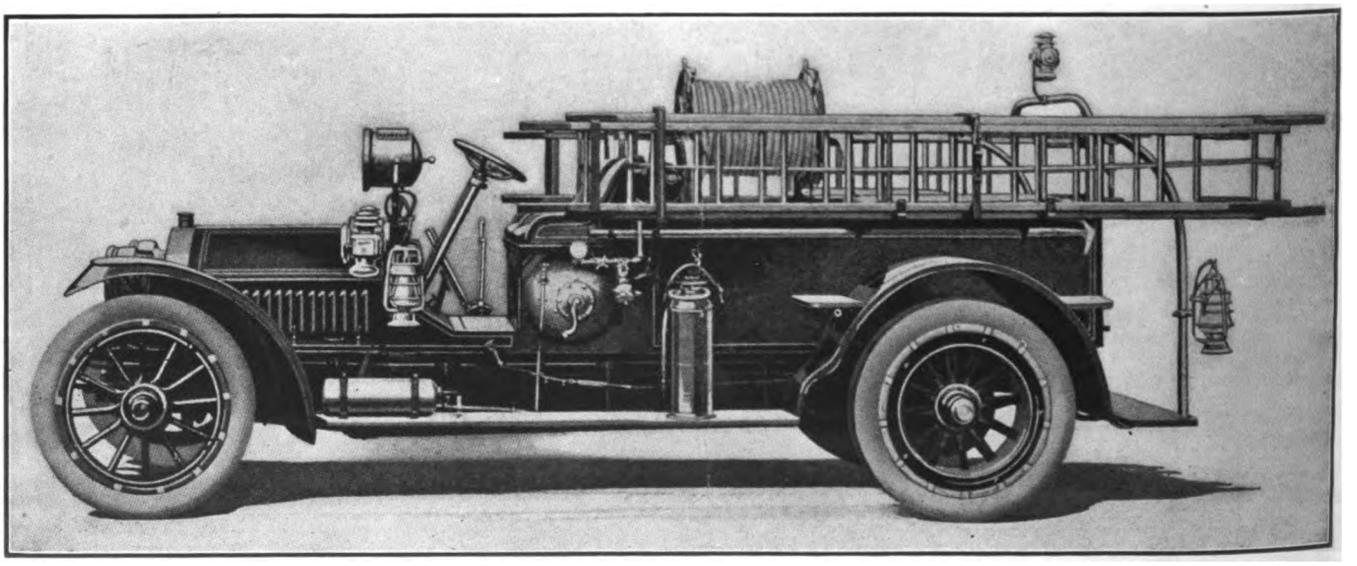
FIRE DEPARTMENT NOTES

Presented herewith is a general view of a Locomobile combination hose and chemical wagon, made by the Locomobile Company of America, Bridgeport, Conn., duplicates of which have been furnished to a large number of fire departments throughout the country. These have given splendid satisfaction under all conditions of service and are more or less well known in various sections.

The motor is a four-cylinder, water-cooled unit, of Locomobile design, rated at 53 horsepower at 1300 revolutions a minute. The carburetor also is of the firm's own design, of the float feed type with single jet, and hot air connection with regulator. The fuel tank is with capacity as specified, up to 25 gallons, and is located on a superstructure behind or underneath the driver's seat. Feed is by gravity. Ignition is by high-tension dual system, magneto and storage battery. Cooling is accomplished by a honeycomb radiator with gear driven centrifugal pump. Lubrication is by force feed oiler, supplying oil under pressure to the main bearings and keeping the level constant. Additional oil is furnished the bearings by collecting the splash in cups cast in the bronze crankcase. The capacity is two gallons.

The transmission is four speed selective, housed in a bronze case. The clutch is a leather faced cone member of large dimensions with springs underneath the leather to prevent gripping. Drive is by double chain. The frame is of alloy steel of highest tensile strength and elastic limit, heat treated. Springs are semi-elliptic, of the finest alloy, two inches wide. The front members are 40 inches length and the rear 50. The front axle is of alloy steel, I beam section, solid Locomobile forging, heat treated, while the rear member is the same, the driving stresses being transmitted to the frame through strong distance rods. Emergency brakes are expanding on sprocket drums attached to the rear wheels, carefully balanced and equalized. Service brakes are contracting on countershaft, of large size and very effective.



Wheels are of the artillery type, 40 inches diameter, of selected second growth hickory, and run on annular ball bearings, front and rear. The wheelbase is 148 inches. Tires are of the bolted-on type, being 40 by six inches, front and rear. The body is furnished in any design, to conform to the customer's specifications. The standard equipment includes two large acetylene headlights, combination oil and electric side and rear lamps, battery, horn, jack, tool bag, full kit of tools, and Prest-O-Lite tank.

In July the working efficiency of the department in Hartford, Conn., will be greatly increased by the addition of three Pope-Hartford combination chemical and hose wagons and two new chief's cars of the same make, produced by the Pope Manufacturing Company of that city. Orders for these cars have been placed after a thorough trial of two Pope-Hartford chemical engines and the deputy chief's wagon now in use.

Hartford's first Pope-Hartford apparatus was put into commission in June, 1910, and it proved so satisfactory that the second chemical engine and the runabout were purchased the following year. Now, besides placing the large repeat order chronicled above, the fire board announces a plan for the complete motorization of the department within a year, thereby eliminating in a large measure an annual expense of $12,000 for maintaining horses, which now do no actual fire fighting duty.

Among the other towns and cities which have placed repeat orders for similar equipment with the Pope Manufacturing Company may be mentioned the following: Westfield, Mass., two; Fall River, Mass., two; New Haven, Conn., four; Jersey City, N. J., three; Brockton, Mass., two; Middletown, South Manchester, Bristol, Branford and Danbury, Conn.; Worcester, Pittsfield, Mansfield and Lynn, Mass.; Passaic, Bayonne, Kearney, Park Ridge and Nutley, N. J.; Port Chester, N. Y.; Wilkesbarre and Butler, Penn.; San Bernardino, Berkeley, Santa Rosa and Santa Barbara, Cal.; Medford, Ore.; Kansas City, Mo., and Terre Haute, Ind. Included in the list of cities now having apparatus manufactured by this concern are: Taunton and Northampton, Mass.; Rochester and Hastings-on-the-Hudson, N. Y., and Portsmouth, N. H.

Chief S. W. Hunter of Springfield, O., has kept an accurate account of the cost of maintenance of the motor fire engine in his department and recently submitted a report to the mayor, covering the entire time since the vehicle was placed in commission. The apparatus has a 70 horsepower

Type of Locomobile Combination Hose and Chemical Wagon, Which Has Met with Decided Success in Numerous Installations.

Digitized by Google

motor. Its speed is 60 miles an hour. It pumps 700 gallons of water a minute and is loaded with 1000 feet of 2.5-inch cotton rubber hose, two three-gallon chemical fire extinguishers, one hard and one soft rubber suctions, one 20-foot extension ladder and one 10-foot roof ladder, and six men. The machine was placed in service June 9, 1909 and the account follows:

Gasoline, grease, oil, 1909	$35.24
Gasoline, oil, repairs, 1910	78.32
New tires and adjustments, 1910	252.75
Gasoline, oil, repairs, 1911	107.58
New tires and adjustments, 1911	222.00
Total cost	$695.89
Total miles travelled	1316
Total hours, engine pumped	16
Total runs made	494

Although the Stegeman Motor Car Company, Milwaukee, Wis., has devoted its attention heretofore to the production of industrial transports varying in load capacity from one to six tons, it is of interest to note that it has entered the fire apparatus field. An accompanying illustration presents the Stegeman fire insurance patrol wagon in service with the Milwaukee Board of Fire Underwriters, and it is the second piece of motor driven equipment in that city. The Stegeman patrol is constructed along truck lines, to withstand heavy service and the severe test of negotiating the unimproved roads in the outlying sections, which is the particular field of this vehicle. In order to effect the greatest safety and overcome the ever present danger to cars of this weight at high speed when rounding sharp turns or corners, the machine is designed with underslung springs, so as to secure a low centre of gravity. An additional factor along this line is the provision for a majority of the weight on the rear wheels. It is maintained that these work together in holding the car to the road in extreme hazards, preventing the danger of overturning and permitting more positive control by the driver.

The motor is of the four-cylinder vertical type, giving 50 horsepower by dynamometer test with direct drive on high speed, or when travelling from 35 to 40 miles an hour. The drive is by jackshaft to the rear wheels, through enclosed chains running in bath of lubricant. All operating parts are enclosed and run in oil or grease. Oil holes have been eliminated and lubrication throughout is furnished by large and positive grease cups. The frame is of pressed steel, reinforced with five cross sections and strengthened by thrust rods between spring centres. All mountings of the wheels are on ball bearings with a special thrust bearing to take up excessive side strains in making the necessary turns, so frequent with fire apparatus. The rear axle is of chrome nickel steel, guaranteed against breakage. The springs are semi-elliptic, front and rear, made of silico manganese steel, and also are guaranteed for life. Supplementary coil springs and shock absorbers take up all excessive spring action and all injurious rebound.

The body is constructed of welded steel, eliminating all rivets. Lockers are built on both sides with a through centre aisle. The cushions are fastened to the locker cover and when raised are automatically held in position to permit of quick removal of the 32 large canvas waterproof covers utilized by the crew in protecting property in time of fire. The driver's seat is heavily upholstered and divided into two compartments, one for the operator and the other for the captain. The duty of operating signals is delegated to the latter, leaving the driver free in his control of the car. The gong is operated by the right hand and the siren horn through a lever depressed by the left foot.

A large acetylene searchlight is automatically lighted by electricity and the motor is equipped with a self-starting device, putting all of the mechanism into immediate control by automatic appliances. The tires are of the airless cushion type, with large dual equipment in the rear. The control is of the well known Stegeman design with left hand position of driver and right hand shifting levers.

The patrol was placed in service in midwinter and was given an extreme test in climbing all the steep hills of the city through a deep fresh fall of snow, in which trial the low speed was never employed. It is stationed at house 2, Ninth and Calena streets, and covers the outlying sections of the north, east and west sides. Its squad includes eight men.

Fire Insurance Patrol Wagon Mounted on Stegeman Chassis and in Service with the Board of Fire Underwriters in Milwaukee, Wis.

The board of fire wardens in Nantucket, Mass., has contracted with the Knox Automobile Company, Springfield, Mass., for a chemical engine, which is to be delivered to the call company of 10 men within three months. With its complete equipment the engine will weigh 6000 pounds. It will be driven by a four-cylinder motor of 50 horsepower, and will be equipped with all the latest fire fighting features.

The city council of Trinidad, Col., has ordered the immediate purchase of an automobile fire truck at a cost approximating $5000.

The fire commissioners of Southington, Conn., have placed an order with the Knox Automobile Company, Springfield, Mass., for a combination chemical and hose wagon, to be delivered in August.

The board of aldermen in Nashua, N. H., is considering an appropriation of $6000 for the purchase of automobile equipment.

The fire department in Hoboken, N. J., has ordered a 30 horsepower American car, made by the American Motors Company, Indianapolis, Ind., for the use of Chief Dunn.

Digitized by Google

Seven years ago the Detroit fire department purchased two friction driven Cartercars, made by the Cartercar Company, Pontiac, Mich., for the use of its deputy chiefs. These machines gave such satisfaction that the number has been increased to seven, the order for five more having been given only recently. The original Cartercars are still running and are in active service daily.

The city of Pawtucket, R. I., has appropriated $7500 for the purchase of motor fire apparatus to replace that now stationed at house 1, which is to be transferred to South Woodlawn.

Mayor P. W. Clement of Rutland, Vt., has laid before the city council a resolution appropriating at least $5000 for the purchase of automobile fire equipment.

As is well known the city of Birmingham, Ala., is deeply interested in motor fire fighting apparatus, having decided to replace all of its horse drawn equipment. During the first month the present 14 pieces of automobile apparatus were in service the cost proved a welcome surprise to the officials, being set forth in the following table:

Company	No. of Alarms	Blocks Travelled	Gals. Fuel	Gals. Oil	Lbs. Grease	Total Cost
Hose 1	45	578	55.0	1.00	.25	$5.81
Hose 2	50	930	35.0	2.12	.25	6.71
Hose 3	32	500	35.5	.81	1.00	5.11
Engine 3	21	325	46.0	2.25	1.00	6.82
Hose 4	32	434	30.0	2.50	1.00	5.17
Hose 5	13	219	15.0	1.00	...	2.82
Hose 6	29	360	35.0	1.75	.75	5.08
Hose 9	6	105	35.0	1.25	1.25	3.89
Hose 10	12	182	54.0	3.12	.75	6.35
Engine 11	27	760	61.0	2.50	...	6.85
Hose 12	4	52	30.0	.50	3.06	3.30
Engine 13	6	76	8.0	.50	...	.95
Hose 16	9	176	10.5	1.00	.12	1.13
Hose 19	5	66	10.0	.75	...	3.73

The 14 pieces answered 144 alarms, practised 39 hours, traversed 4765 blocks, used 360 gallons of gasoline, 20.31 gallons of lubricating oil, eight pounds of pressure grease, changed two Prest-O-Lite tanks, replaced 24 dry cell batteries, one spark plug and one gas burner, at a total cost of $63.72, an average of about $4.50 for the upkeep of each machine. Of course this does not include interest on the investment, depreciation or tires. However, when it is remembered that the cost of horses for the 14 pieces of apparatus which these replaced averaged $450 a month, without counting the accidents to horses, men and machines, the difference in favor of the automobiles is quite marked, to say the least.

Through the efforts of the municipal committee of the Board of Trade in Philadelphia, $41,000 has been placed at the disposal of the department for the purchase of automobile equipment. George D. Porter, director of public safety, and Chief Waters of the fire department are engaged upon the work of preparing the specifications, and it is understood that the vehicles will be equipped with life saving devices and fire fighting appliances, and constitute what will be termed a "Flying Squadron."

Recently, one of the citizens of New York City criticised the department for the purchase of the gasoline pumping engine which has been in service for some months past. In reply Fire Commissioner Johnson says:

"I agree that the pumping efficiency of the new gasoline pumping engine is not all that it might be or will be. Engine 39 is capable of pumping 744 gallons of water a minute, or about as much as a second size steam engine. A first size steam engine will pump 900 gallons a minute. The cost of engine 39 was $10,000. A steam engine costs $5000.

"If this were all there is to it, there would be no room for argument, but there is more. When we buy a steam engine we have to buy three horses at $350 each. The upkeep of each horse is $360 a year, or $1080 for the three. An engine driver costs us $1400, and an engineer $1500. Therefore a new engine costs us $10,130 for the first year. The following years it costs $5130 without cost of repairs or fuel.

"Automobile fire engine 39 cost us $10,000. A driver, who also attends to the gasoline pump, draws a salary of $1600. Gasoline and repairs cost us $200. Therefore, an engine of this type stands us about $11,800 the first year and $1800 each succeeding year."

Norwich, Conn., has followed the example set by other progressive cities in installing a piece of motor propelled fire apparatus which is a combination hose and chemical wagon made by the Pope Manufacturing Company, Hartford, Conn. The body is fitted with seats running lengthwise and accommodates eight men. The equipment consists of 1000 feet of 2.5-inch water hose and a chemical tank of 35 gallons capacity which is located under the driver's seat. The hose is carried in a metal basket having a capacity for 250 feet. Ladders, axes, etc., complete the equipment.

Marlboro, Mass., is considering motor propelled fire apparatus and President Bourdreau is using his influence to convince the members of the board of aldermen that the automobile would not only vastly increase the efficiency of the department but it would save the town at least $300 a year. The sentiment of the representative business men is in favor of the change from the horse drawn equipment.

The following cities and towns have made appropriations for or are considering the purchase of motor propelled fire apparatus: Bellingham, Wash.; Milwaukee, Ore.; Port Huron, Mich.; Terre Haute, Ind.; Freeport, Ill.; North Vancouver, B. C., Canada; Braintree, Mass.; Youngstown, O.; Lynn, Mass.; La Grande, Ore.; Arlington, Mass.; Macon, Ga.; New Brunswick, N. J.; Montpelier, Vt.; Pasadena, Cal.; Milwaukee, Wis.; Shelton, Conn.; Petaluma, Cal.; Portsmouth, N. H.; Passaic, N. J.; Tennallytown, D. C.; Canton, O.; Visalia, Cal.; Barre, Vt.; Portland, Ore.; New Britain, Conn.; Racine, Wis.; Sioux City, Ia.; Andover, Mass.; Reading, Mass.; Columbus, O.; West Springfield, Mass.; Plymouth, Ind.; Milton, Penn.; Pittsfield, Mass.

Newburyport, Mass., desires the automobile to replace its horse drawn fire equipment, but the News of that city comments editorially as follows: "If the city of Newburyport is to purchase automobile fire apparatus it should do so only after there is a sale of some of the equipment now in service. A city of the size of Newburyport which has four engines in commission is a rare one and has equipment sufficient to cope with any usual conflagration and most unusual ones. To spend money to add to this equipment, while all this is to be retained and the department kept up to its present size, would be waste. Let us keep the department in splendid shape, but let's not go crazy about it. A piece of automobile apparatus would be a fine thing, but it should come only in place of a reduction in other lines, and not in addition to what we already have."

Doubtless there are other towns and cities which occupy a position similar to that of Newburyport, but the economic principles involved should be taken into consideration, as it has been proven time and again that automobile apparatus means a saving of several hundred dollars a year over the horse drawn equipment, to say nothing of the reduction in fire losses due to the speed of the machine. The question of insurance rates is also worth considering.

KNOX AMBULANCE FOR EXPORT.

AN ambulance possessing many excellent features of construction and equipment and which is said to be the most perfectly appointed ever built in this country, has been completed by the Knox Automobile Company, Springfield, Mass., for foreign shipment. The demands for modern hospital practise require ambulances fitted with all possible conveniences as it has been demonstrated that prompt attention to the condition of the patient while en route to the hospital is an important factor in effecting recovery, and the latest Knox vehicle has been designed to fulfill all these requirements.

In the illustration herewith is presented the ambulance, with chassis of standard Knox construction throughout, being equipped with a four-cylinder, four-cycle, water-cooled motor, rated at 40 horsepower. The wheelbase is 134 inches and the wheels are equipped with 38 by 5.5-inch pneumatic tires single in front and dual at the rear. These large shoes with long semi-elliptic springs on the rear, provide extremely comfortable riding qualities.

The body is unique because of its design and appointments. The frame is of carefully selected ash, strongly braced to insure lightness with strength and freedom from squeaking or rattling. Sheet aluminum is utilized as the outside covering, and this is made in seamless panels, while the inside is sheathed with three-ply laminated white wood. The flooring is of ash, covered with linoleum.

Back of the driver's seat the body is divided into two compartments, the forward end having a door at either side, also a folding seat facing forward for the doctor's use. This compartment serves as a side entrance or a passage way for the rear compartment and opens directly into the latter without intervening door. Directly behind a partition at one side of the vehicle are located two cots, one above the other, supported by springs. Each cot is of the folding type, adjustable to any angle, and is supported by a metal slidable tray into which it moves readily. Below the lower cot is a large locker for the convenient storage of medicines, etc.

New and Richly Appointed Ambulance Constructed by the Knox Automobile Company, Springfield, Mass., for Service Abroad—It Is Fitted with Modern Conveniences for Care of Patients and Is Unusually Easy Riding.

Two folding seats are provided on the side opposite the cots, one at the head and the other at the foot, and between them, on the side of the body, is arranged a neat folding hot and cold water outfit with sink and drainage tube leading to the outside of the car. A small alcohol lamp serves to heat the water while on the way to secure the patient. In addition to these arrangements, there is a large Thermos bottle equipped with a rubber tube and stop-cock directly over an antiseptic tray and pad, while drinking cups are also provided in a convenient bracket.

Ample ventilation is furnished by three shutter ventilators on each side, under the roof, while additional air may be secured by dropping the windows in the doors. A window on the side opposite the cots, combined with those in the doors, affords excellent light, and double doors at the rear provide ample space for entrance and exit.

The interior of the body is finished in pure white enamel, presenting a particularly clean and sanitary appearance, while the exterior is also white with a fine gold stripe. For night use the entire car is lighted by electricity, current for the two large dome lamps being supplied by a dynamo driven by the motor. Storage batteries supply electricity when the motor is not operating and these are automatically charged by the generator. Every modern convenience for the comfort and care of a patient has been installed in this ambulance.

WORKING FOR A BUS LINE.

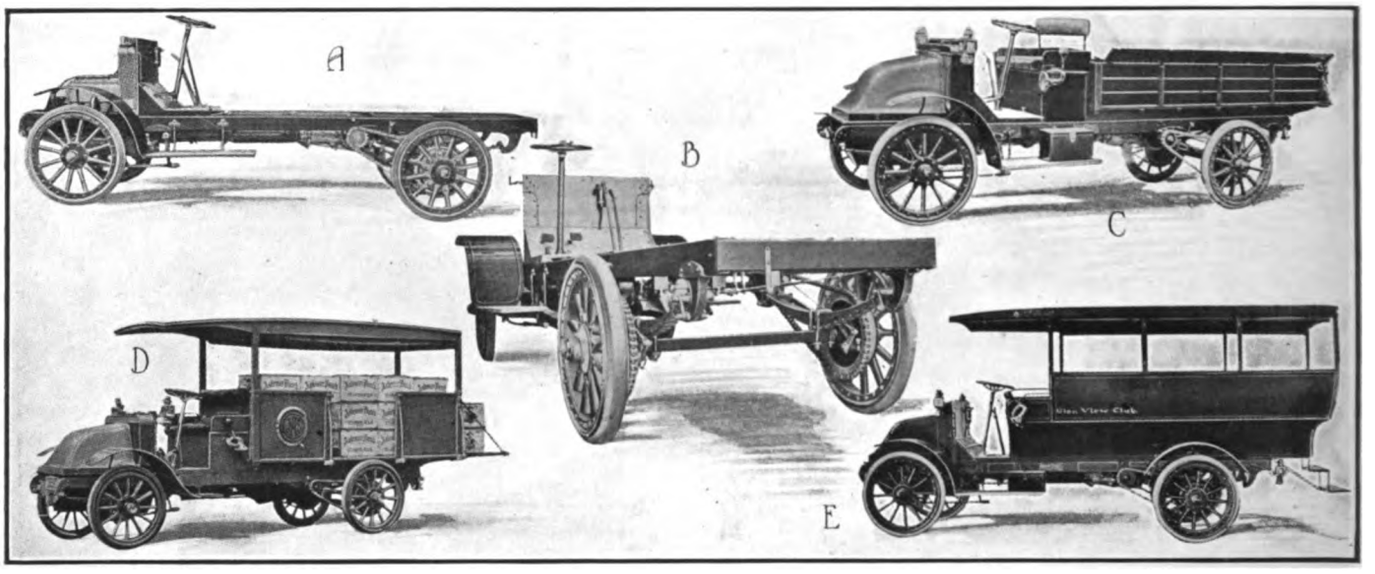
The Commercial Club of Fort Dodge, Ia., is working earnestly for the establishment of a motor 'bus line and at a recent meeting a committee was appointed to solicit funds for the new project. An active campaign is in progress and the club expects to secure the line in a short time.

SELECTS SAMPSON TRUCK.

G. L. Summey, chief engineer of the Chase Rolling Mills Company, Waterbury, Conn., said to be one of the largest brass manufacturing concerns in the world, has been investigating motor trucks for a number of years. In fact, it may be stated that the Chase company was one of the first concerns in Waterbury to test commercial vehicles. Its factory is located on top of a long hill, reached over vitrified brick pavements from the centre of the city, and the problem of hauling by horses is by no means easy of solution. After spending some $7000 and three years' time in investigating all makes of trucks, Mr. Summey has decided upon the purchase of a Sampson, made by the Alden Sampson Manufacturing Company, Detroit.

REPRESENTS REMY IN CANADA.

Taylor & Arnold, Ltd., of Winnipeg and Montreal, Can., one of the largest railway supply houses in the Dominion, has become the sole representative of the Remy Electric Company, Anderson, Ind., maker of Remy magnetos. The various branches maintained by this concern will be utilized as service stations for the Remy products, as well as distributing and selling points.



W. S. Hathaway of Kansas City, Mo., has organized the Southwest Motor Company, which will represent Reo trucks, made by the Reo Motor Truck Company, Lansing, Mich., in that section at 1616-1618 Grand avenue.

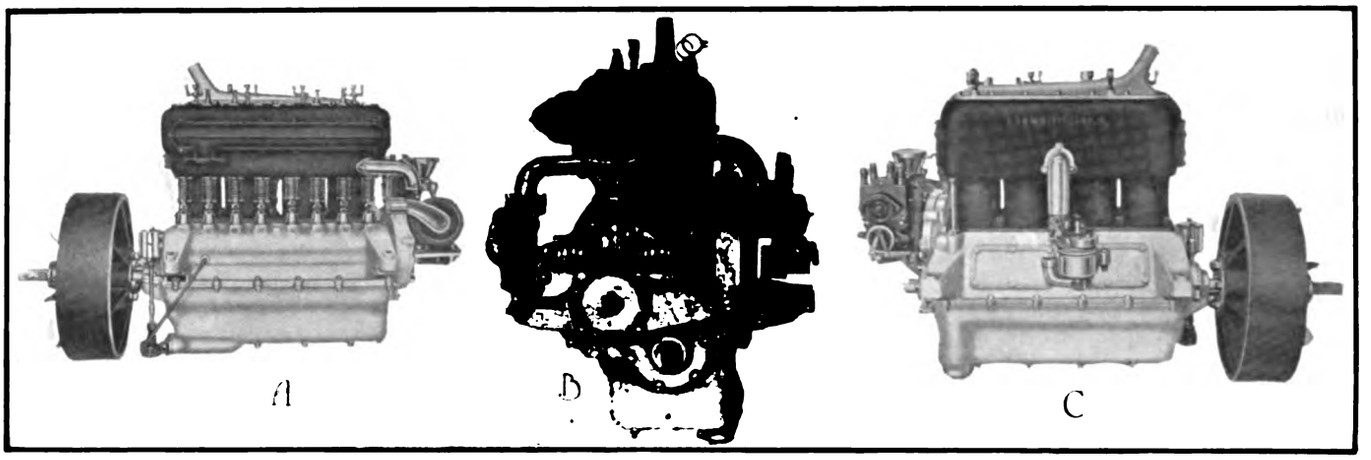
FEATURES OF ADAMS CONSTRUCTION.

SIMPLICITY of construction, and consequently of operation, has the effect of an axiom with the Adams Bros. Company, Findlay, O., in the production of the Adams one-ton truck. Complexity of parts is held to mean congested cost of upkeep and needless necessity for repairs and replacements. With the object in view of keeping the cost of operation and maintenance to a minimum, the Adams chassis has been built with as few working parts as careful design and extended experimentation have demonstrated is possible. There is claimed to be little chance that parts will become deranged because of careless driving, but regardless of this, all components have been designed and built interchangeable, being constructed by special machinery and from the best material obtainable.

The Adams Bros. Company built successful machinery over 40 years ago. In engineering, foundry and machine practise it has held front rank. Its decision to enter the commercial vehicle field was made after thorough consideration of the needs, and the Adams truck was conceived with the specific idea of measuring up to the high standard set by the other products of the concern. Each component is constructed to perform its particular duty and to work in complete harmony with every other part and piece as a perfected whole.

Adams One-Ton Truck: A, Side View of Chassis; B, Rear View of Chassis, Showing Axle Construction and Spring Suspension; C, Standard Express Body; D, Special Delivery Body with Removable Panel; E, Fitted as a Club 'Bus.

One feature cannot be emphasized too strongly. The Adams truck is not an assembled vehicle, but is constructed throughout in the factory of the Adams Bros. Company. Everything from the motor and radiator back to the rear axle is the product of this concern in its own shops. The various components have been subjected to the most rigid tests and the finished product is thoroughly tried out under every road condition before being placed upon the market. As a result, the Adams one-ton truck not only represents simplicity of construction, but inherent reliability, which is backed by a substantial guarantee covering a period of one year from the date of delivery.



Something may be said of appearance, and in this respect the maker claims originality of design and careful attention to detail. Accessibility is another important factor, and with this in mind, the water pump, oil pump and gauges, carburetor, magneto, oil filling funnel and breathing tube have been so placed as to be reached easily. The radiator is situated behind the engine, following foreign practise, and is readily filled from either side. This location is held to eliminate entirely all danger of casual injury, and at the same time makes for added accessibility, in that the hood is hinged at the top of the radiator so as to be lifted from the front, exposing the entire power plant for work or removal.

After careful consideration of the matter of driver's location, it has been decided to place the steering wheel at the left. This not only provides for easy access to the seat from the sidewalk or curb without passing around the truck but is held to make for more satisfactory operation in congested traffic. The control levers are placed in the centre of the floor boards, adding still another feature of simplicity and accessibility.

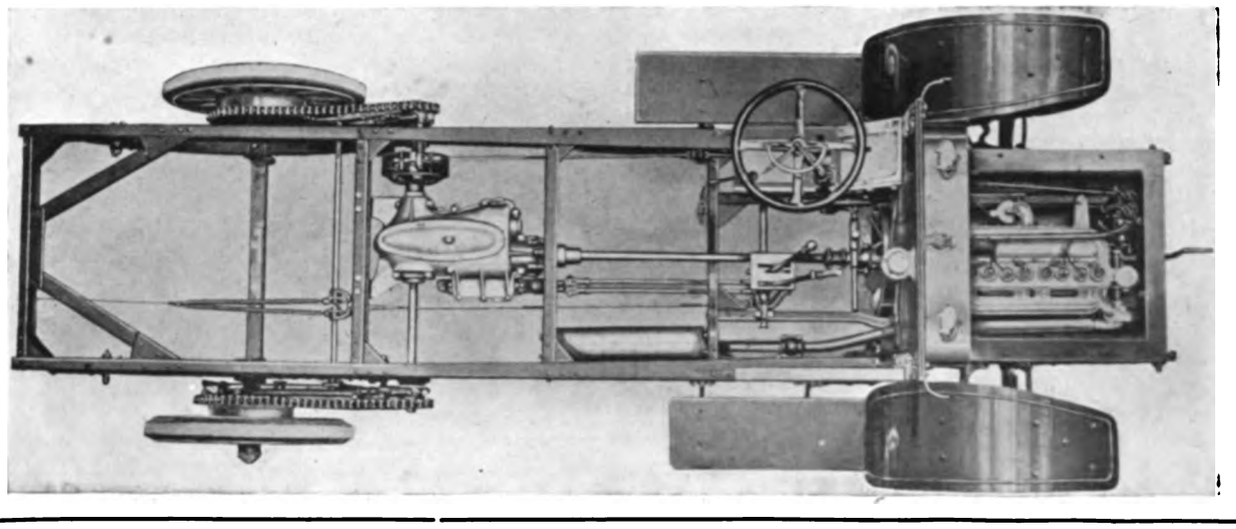
The motor is a four-cylinder, four-cycle, water-cooled unit with bore of 3.875 inches and stroke of five, rated at 30 horsepower. The cylinders are cast en bloc of a very high grade material, and liberal provision has been made for ample water circulation between each cylinder. Pistons are of a special grade of cast iron, accurately ground and fitted with piston rings of the same material, ground on all working sides. The crankshaft is drop forged of 3.5 per cent. nickel steel. It has large diameter and unusual length of bearing journals, with three bearings of a special composition insuring excellent service. The camshaft is also drop forged with integral cams, being entirely enclosed in the upper half of the crankcase and actuated by means of spiral gears. All valves are mechanically operated and interchangeable. They are of liberal diameter and located on the right side of the motor.

The crankcase is made of the finest grade of aluminum alloy, and is so designed that the upper half contains all the working components comprising the motor, while the lower half constitutes the oil reservoir supplying the lubricant to all working parts. The lubrication system is so arranged as to offer the combined advantages of the constant level splash and force feed systems. Positive water circulation is effected by a spiral gear driven centrifugal pump, aided by a fan located in the flywheel. The radiator is of the vertical tube type, provided with two filling caps, one on either side, and is carried at the rear of the motor on flexible supports. This location is held not only to protect this member from possible collisions, but the mounting is such as to eliminate any damage emanating from the unequal motions to which the side rails of the frame are

Digitized by Google

Three Views of the Adams Motor: A, Left Side, Showing Exhaust Manifold and Valve Arrangement; B, Front, Presenting Location of Magneto, Water Pump and Oil Filler; C, Right, Indicating Position of Carburetor and Inlet Manifold.

necessarily subjected in traversing rough roads.



Ignition is by dual system, employing an Eisemann high-tension magneto. Steering is accomplished by an irreversible screw and nut Ditwiler type post located on the left, permitting a clear view of the road in either direction. The spark and throttle control is mounted on the steering wheel, and with the location of magneto and carburetor, all connections between these and the steering post are established directly by two straight rods, doing away entirely with the intricate net work of numerous connecting rods, bell cranks and levers. The carburetor, which is a Kingston, is also controlled by pedal. The arrangement and location of magneto, water pump, filling funnel and oil gauge on the front end of the engine affords extremely easy access to any part of the motor by simply lifting the hood, and this may be removed without disturbing any other adjoining part.

The clutch is a Wells expanding disc member, so designed as to permit of easy engagement, and it is claimed that the car will pick up smoothly without undue strain on the transmission, axle or other driving parts. The transmission is of the selective type, providing three speeds forward and reverse, direct drive being on the high. This is located in the centre of the car and connected with the clutch by the driving shaft and universal joints which take up all variation in alignment, resulting in traversing rough roads. All working shafts are of special alloy steel. Final drive is by double side chain, having 1.25-inch pitch and .75-inch roller.

Brakes are three in number, one service member on the jackshaft, operated by pedal, and two emergency members on the rear wheels, operated by hand lever. The levers are located in the centre, where they are operated in a natural manner by the driver's right hand. The frame is of special high grade pressed steel, 38.75 inches wide, offset between the front wheels by a generous U section. The axles are of Sheldon manufacture, of special design for most satisfactory service under the severest conditions. Springs are semi-elliptic, front and rear, the former being 2.25 inches width and 44 inches length and the latter 2.5 inches width and 44 inches length. Wheels are of the artillery type 36 inches diameter, fitted with three-inch solid tires in front and 3.5-inch in the rear. The wheelbase is 121 inches and the tread 56.

Any standard body is fitted, and the company is prepared to build any type of special equipment as desired. Accompanying photographs give some indication of the special bodies which have been produced for varying classes of work. The regulation loading platform has an inside measurement of eight feet 10 inches length by three feet 10 inches width. The standard color is battleship gray, although the painting is optional. With the machines are furnished two electric and oil side lamps and tail lamp, full set of tools, jack and horn. The gasoline tank has capacity of 15 gallons.

The Adams Bros. Company is confident that it has met every requirement in simplicity, stability, efficiency and appearance. In making sales, every care is taken to provide a vehicle and body suited to the particular needs of the individual case.

Plan View of Adams One-Ton Chassis, Indicating Simplicity of Design and the Limited Number of Working Parts.

NEW FREIGHTERS IN PORTO RICO.

Systematic Attempt to Solve the Problem of Long Distance Haulage, in Which Industrial Transports Will Compete Actively with Railroad Service.

By R. W. Hutchinson, Jr.

WHILE the motor truck has been regarded mainly as a freight carrying institution suitable for city service, it is of interest to note that it has proven itself of greater efficiency than the railroad for certain conditions of moderate distance haulage. That such a radical step has been taken by a large general trucking corporation on the island of Porto Rico, utilizing industrial transports for haulage that can be considered in the long distance class, indicates very forcibly the degree of dependability which can now be placed in the first class commercial vehicle. That the motor truck has proven itself adaptable under the most extreme conditions of climate and roads also indicates that the "new freighters" can no longer be regarded as machines for service only on nicely paved streets.

One of the largest installations of motor trucks for general transportation service has just been made by the International Motor Company, New York City, maker of Mack, Saurer and Hewitt vehicles, with the Porto Rico Motor Company, which has bought 30 Saurer cars. Before the order was placed, the traffic department of the International company studied the conditions in Porto Rico at close range. The selection was made after an investigation of a number of makes of trucks and the decision was reached after a thorough knowledge of one of the most serious factors against the use of such vehicles under road conditions as severe as those which exist on that island, that of tire troubles. Every item of transportation cost was charted and not the smallest detail was neglected in predetermining the lucrativeness of the enterprise.

The First Installment of the Thirty Saurer Cars Recently Shipped by the International Motor Company for Freight Service in Porto Rico.

The Island of Porto Rico has a population approximating 1,114,000, and a total area of 3600 square miles. The people are distributed generally all over the island with the largest cities and towns near the coast. The density of population is greater than that of any other sub-division of American territory, with the exception of Rhode Island, Massachusetts and New Jersey. The island is divided into 66 municipalities, and the incoming supplies and outgoing products pass through the principal towns.

The chief transportation system is the American Railroad of Porto Rico and certain allied railroads. This is a narrow gauge line extending along the coast from Carolina, east of San Juan on the north coast, around the west end of the island and along the south coast to Guayama. A branch of this system extends from San Juan to Caguas, and this is the only branch of importance reaching the interior, with the possible exception of the Valdez road between Catano and Bayamon. Along the east coast of the island there are several separate railroads owned by the Sugar Centrals, and used for hauling cane. It seems probable that at some later date these separate railroads will form a part of the general system, extending all the way around the island.

The main ports are San Juan and Arecibo on the north shore, Ponce and Arroyo on the south shore and Mayaguez and Aguadilla on the west. There are certain minor ports, such as Fajardo Playa, Humacao Playa, Aguirre and Guanica. There are no land locked harbors on the island, with the exception of San Juan, Aguirre and Guanica; all of the other points used as ports are open roadsteds. When ships are discharged or loaded in these latter, it is necessary to use lighters and other vessels which maintain a coastwise shipping service.

The transportation of freight between the coast and the interior is at present carried on almost entirely by means of bull carts, and the service given by the railroad is so unsatisfactory, particularly with regard to the shipments of less than carload lots, that bull carts are competing with the railroad on roads parallel to their lines.

The business of the island is increasing at a rate varying from 16 to 20 per cent. a year, as shown by the reports of the customs service, and the need of an adequate system of transportation is becoming more and more imperative, especially between the coast and the interior. There is a wide variation in the rates charged for transportation by bull carts, this being from 15 to 40 cents a ton-mile. The number of cattle on the island is diminishing and as more land passes under cultivation the pasturage for cattle is decreasing. The grades in the interior prohibit the construction of railroads through this section for a long period, if at all.

So imperative has become the necessity for additional means of transportation that some American mules have been imported. These are used only to a very limited extent, however. There are at present about 45 motor trucks on the island, and approximately one-third of these are of the first class. These are usually owned in lots of one to three by individuals, although there are two or three automobile truck companies. In general, it may be said that

Digitized by Google

with the exception of the Atlas Transfer Company, which is operating from six to eight trucks in the immediate vicinity of San Juan, no attempt has been made to install an automobile truck system along anything like broad lines, previous to that described herein.

The lands on which coffee, tobacco and a portion of the sugar are raised are in the interior of the island and the principal use for an automobile would be in carrying provisions and mechandise into the interior and bringing out these products. The movement of provisions and merchandise toward the interior towns is comparatively steady, with a somewhat larger volume in January than in other months of the year. One feature of this movement is quite pronounced, in that the bulk of these goods come from the coast cities, such as San Juan, Ponce, Guayama and Arecibo. The reason for this is found in the fact that the merchants in these cities are in a better position to give credit than are those of the towns of the second grade.

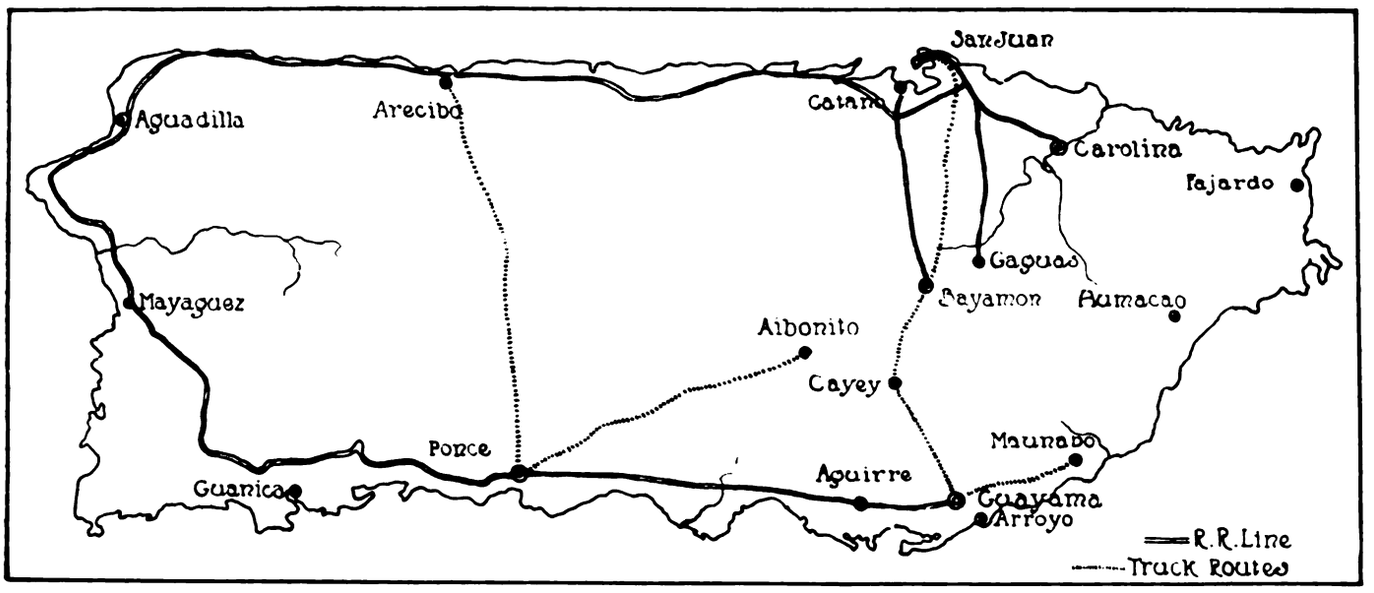
The roads of the island are divided under two systems, one known as the insular, which penetrates most of the important sections and which in a few years will form a very complete network, and that known as the municipal. The first is under the care of the insular or federal government and is a magnificent system of macadamized roads with grades seldom more than seven or eight per cent., and in no case exceeding 15. The second consists of ordinary dirt roads, maintained by the different municipalities, or local governments, and forming connecting links between the insular roads. A great many of these are practical for motor trucks, except during the season of heavy rains, which occurs between Sept. 1 and Dec. 1.

It is not proposed that the automobile truck system to be used by the Porto Rico Motor Company shall operate over the municipal roads except in special instances, but it is proposed to operate these trucks over the insular roads, which now touch, or will very shortly touch all of the main towns. The system may be considered as having been separated into six divisions as follows: Division 1, San Juan-Cayey; 2, Bayamon; 3, Ponce-Aibonito; 4, Ponce-Arecibo; 5, Guayama-Cayey; 6, Guayama-Maunabo. The points at which garages are required are San Juan, Caguas, Ponce, Arecibo and Guayama.

The organization of the company operating this system is to be along the lines of the diagram presented below. The clerks, stenographers and one of the machinists in each of the shops at San Juan and Ponce will be Porto Ricans, while the officers and the remainder of the employees of the company will be American, as follows:

General Manager

—Superintendent, San Juan—			——Superintendent, Ponce——		
Foreman Bayama	Foreman Caguas	Foreman San Juan	Foreman Ponce	Foreman Guayama	Foreman Arecibo



Stenographer — Cashier and Paymaster

Clerk — Stenographer

Conditions are such that the trucks will be required to operate over roads running through mountainous country. The maximum limit guaranteed by the government for the bridges on the routes is eight tons for one vehicle. The type of freight is such that 10,000 pounds can be handled properly by a stake body 12 feet long, six feet wide and six feet high. A truck to be successful under these condimust be designed particularly for mountain work.

The Saurer truck of five tons capacity fulfills all of these conditions, and is particularly suitable for this proposition. The motor air brakes with which this vehicle is equipped are a decidedly valuable feature in this country. The light weight of the chassis insures the most economical results in tire maintenance.

In connection with this last item, it has been found that on automobiles operating in Porto Rico the costs are exceedingly high for reasons which are not thoroughly understood. A certain tire company, however, stated that it would be willing positively to guarantee its product for the minimum of 5000 miles of travel on the island, and that users of its tires will be given the benefit of a better guarantee if it is found that this figure can be increased.

Map of Porto Rico, indicating Present Railroad Facilities and Cities Which Will Be Served by New Motor Truck System.

The transportation system, which adequately provides for the needs of the territory now under consideration, eventually will control practically all of the interior traffic of the island. Twice as many trucks as those ordered for the initial installation will be needed in the future, and possibly three times as many.

The greatest volume of traffic is found in the central portion of the island. For these reasons it was recommended that the initial installation be confined to that section between San Juan, Guayama, Ponce and Arecibo, as mentioned before. It will be noted that no provision has been made for operating trucks in the neighborhood of Manati, Ciales and Morobis, for the reason that all hauling to and from Manati and Vega Baja is done by railroad and the road between Manati and Vega Alta is not yet completed. This section will be considered later.

New Commercial Car Accessories

Cooper Valve Lifter.

A new type of valve lifter which presents several practical features has been brought out by John J. Cooper, Providence, R. I. It consists of two parts, a U shaped member carrying a hinged lug into which is threaded a screw member, and a lever. The lower end of the former is recessed to fit and engage the slotted portion of the lever. The latter is slightly curved and is equipped with tilting shoes which engage with the retaining mechanism of the valve spring. The upper surface of the lever has a series of notches, these being for the purpose of engaging a brace member which is attached to the handle and so arranged that when the valve spring is compressed the brace slips into place and automatically locks the tool in position, allowing the operator the use of the hands in removing or replacing the retaining mechanism of the valve.

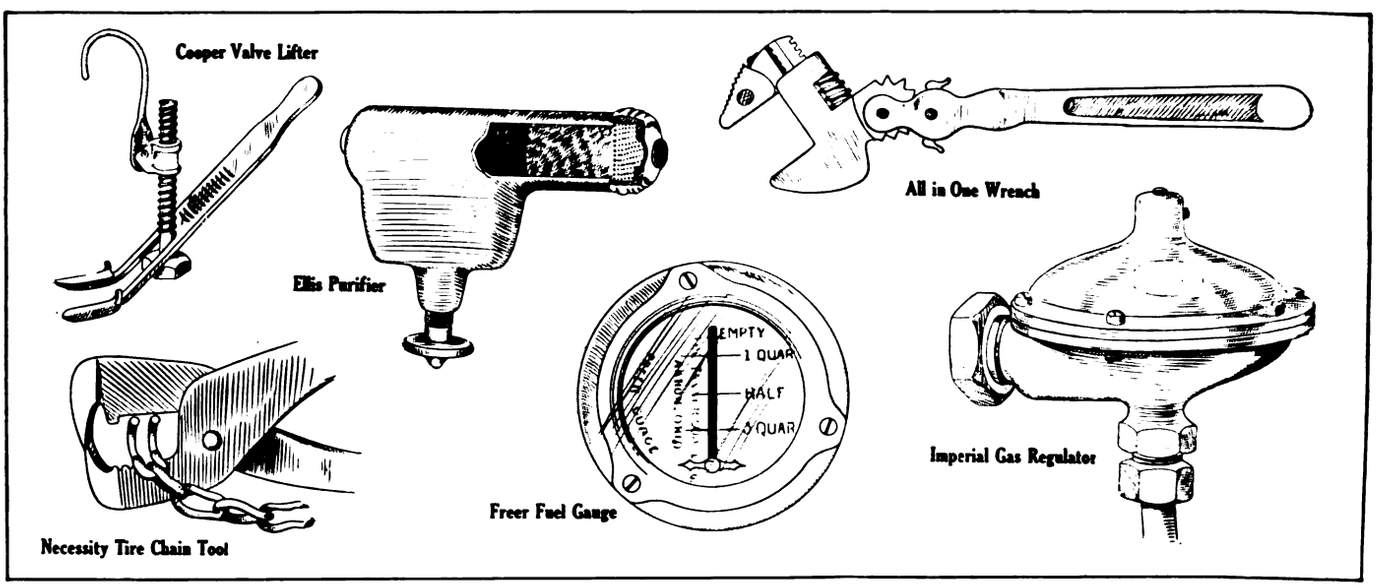
Ellis Fuel Purifier.

The Ellis gasoline purifier, for which the L. P. Rhines Company, Boston, is special agent, is a device for incorporation in the fuel line between the tank and the carburetor. It is simply constructed and the maker states that not only is the fuel purified but fine particles of kerosene, dirt, etc., are absolutely prevented from reaching the vaporizer. The fuel first enters the precipitation chamber, then is filtered through two fine screens, two felts and quartz, whereby foreign elements are retained. Any water in the gasoline lodges in a separate chamber while the fuel rises and passes through the filter to the carburetor. The device is easily drained of the impurities caught by turning a small thumb screw. It is compact, weighs about six ounces and is constructed of an aluminum composition. It comes complete, including brass unions, and these are made in three sizes.

All in One Wrench.

Combination wrenches appeal to operators who do not like to carry a large number of tools in the kit. The Universal Wrench Company, Indianapolis, Ind., is marketing a novel device which it is claimed will perform the work of numerous tools. The jaws of the wrench are adjustable and so constructed that they may be employed for removing nuts or working on piping. Eight different angles may be secured as well as ratcheting in either direction. The tool is nine inches long, constructed of high grade steel and guaranteed.

Macdonald Tire Chain Tool.



The Necessity tire chain tool, manufactured by J. N. Macdonald & Co., Wethersfield, Conn., and for which T. F. Russell & Co., Boston, is distributor, is a device for repairing tire chains. The jaws of the instrument are so constructed that the hooked ends of the chain links may be forced apart and compressed easily, and it is claimed by the maker that repairs may be effected in a very short time.

Freer Gasoline Gauge.

The Freer gauge manufactured by the Tanner Gage Company, Akron, O., is designed to register the amount of fuel in any type of tank and consists of a reading dial attached to the top of the container. The dial is calibrated and a needle or hand indicates the amount of fluid in the tank. The registering member is actuated by a float device in the tank and its construction is such that the maker claims it is impossible for it to get out of order. The reading dial is of glass, .25 inch thick, set between cork washers, and enables the operator to inspect the contents of the tank without danger of explosion when a light having a naked flame is utilized.

Imperial Pressure Reducer.

The Imperial Brass Manufacturing Company, Chicago, has brought out a new device designed to reduce the pressure of acetylene when utilized from a tank. It is incorporated in the line between the container and lamps and the pressure of the gas is automatically regulated and may be reduced as low as two ounces. It is claimed by the maker that a steady and even flow of gas is assured and that considerable economy is effected by the use of the device. It is compact, constructed of high grade materials and in addition to being attached easily, is inexpensive.

Some New and Practical Accessories Which Will Appeal to the Operator, Owner and Manufacturer of Commercial Vehicles, Including Valve Lifter, Fuel Filter, Gasoline Gauge, Etc.

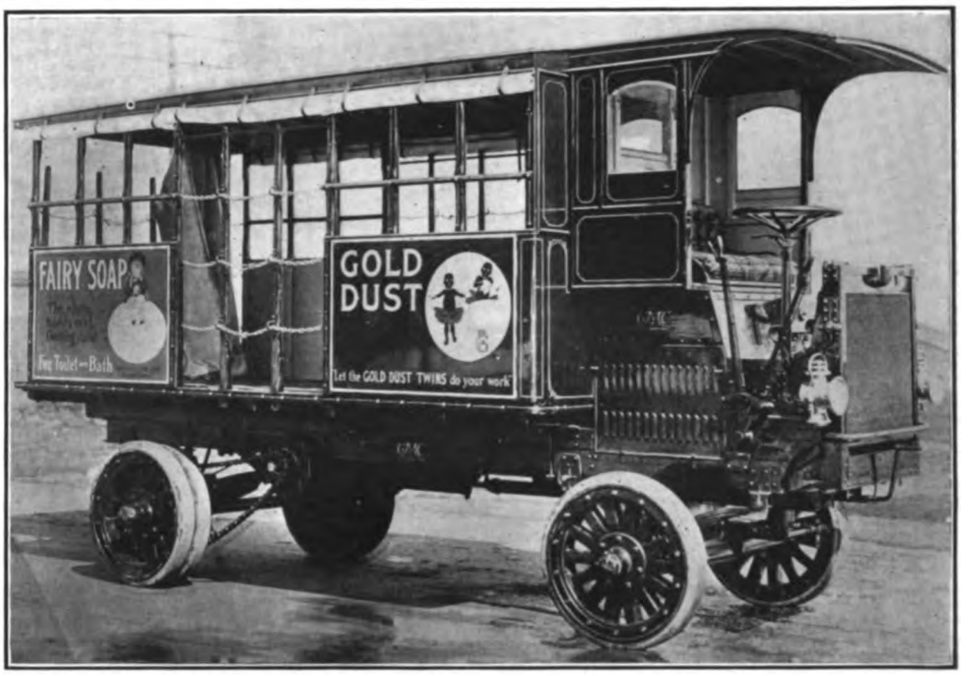
MOTORS IN GERMAN ARMY.

It is stated that the German army now has 600 motor outfits, each comprising a tractor and trailer, having a total carrying capacity of six tons. This is estimated to be sufficient for the supply of rations and forage to at least 10 divisions at the rate of 60 tons a day.



The Austrians are subsidizing similar outfits, but in view of the more undulating nature of the country there, each is intended to carry but five tons. This government recently conducted a very successful 1000-kilometer trial, in which 10 of these motors took part.

G. M. C. AND GOLD DUST TWINS.

Housekeepers throughout the country are familiar with the Gold Dust Twins, a product of N. K. Fairbanks & Co., Chicago, which concern utilizes the 3.5-ton G. M. C. truck, made by the General Motors Truck Company, Detroit, illustrated herewith. It will be noted that the machine is not only used for hauling, but it provides a valuable advertising medium, its sides having two panels on which are outlined the products of the company.

The machine is propelled by a four-cylined, four-cycle, water-cooled motor, having a five-inch bore and stroke and rated at 40 horsepower. The power plant is demountable. Cooling is by cellular radiator and ignition is double, with two sets of plugs, current being furnished by a Mea magneto and storage batteries. A ball type speed governor is fitted to prevent the operator from overspeeding the vehicle. A disc clutch is employed and the transmission is of the progressive type, affording three speeds forward and reverse. Final drive is by side chains.

Two sets of brakes are fitted, these being of the expanding and contracting type on the rear wheels, which are equipped with 36 by four inch dual solid tires. The front members are fitted with 36 by five-inch single solid tires. Semi-elliptic springs are employed in front and full platform at rear. The wheelbase is 138 inches. The driver's position is at the right with right hand control. The body is of the stake platform type with curtains, and the driver is fully protected against the weather by a cab.

G. M. C. 3.5-Ton Truck Utilized by N. K. Fairbanks & Co., Chicago, the Vehicle Serving as a Valuable Advertising Medium as Well.

AMERICAN TIRES IN EUROPE.

It is claimed that while Europe has been producing automobile tires for a number of years, the rubber tread type of non-skid pneumatics, so prevalent in America, is practically unknown there, except as it has been introduced by tourists from this country. That there is a demand for this type of tire is evidenced by the fact that several Continental dealers are seeking for agencies. One of these dealers, M. Adler of Amsterdam, Holland, was a recent visitor in this country and spent some time looking over the tire field. As a result of his investigations he has taken the agency for United States tires, made by the United States Tire Company, New York City.

Mr. Adler operates one of the largest automobile supply houses in Europe, the main store being located in Amsterdam and branches in Paris, Brussels and Birmingham, England. He will handle the entire United States line, including the new patented truck tire. In making his decision he absolutely disregarded the question of price, giving special heed to quality. He claims that while American tires cost more than the European product, the difference in price will be more than offset by the difference in service.

SANITATION AND HORSES.

According to Morris Grabowsky, sales manager of the Alden Sampson Manufacturing Company, Detroit, maker of the Sampson line and a constituent of the United States Motor Company, New York City, sanitary conditions would be improved greatly by a more extended use of the motor truck. He says:

"Statistics credit the cities of this country with using 4,500,000 horses and 200,000 mules. With all the precautions to keep the cities sanitary little progress can be made so long as such an army of quadrupeds parades in endless procession up and down the streets. The clouds of dust which sift above the pavements are not clean earth of the fields, but are filled with disease germs and lingering death. The expulsion of the horse would mean the disappearance of the house fly, by removing its chief breeding source."

VELIES SUCCEED HORSES.

It is surprising to note the number of teaming concerns operating from 100 to 200 horses in Chicago, who are placing orders for contract work. It appears that many of these companies have been a little skeptical about the operating costs of the two and three-ton trucks, but the Zipprich Teaming Company, one of the largest in the city, recently placed an order with the Velie Chicago Branch for a three-ton Velie, which will be devoted to caring for the work of Hart, Schaffner & Marx, the well known clothing maker.

R. T. Houk, for the past year connected with the sales end of the United States Motor Company, has resigned to assume the management of a large mill in Ohio, in which he has been interested for some time.

FOREIGN TRUCK NOTES OF INTEREST

COMPETING WITH RAILROADS.

The recent coal strike in Great Britain served to recall the subject of long distance motor haulage, and the results which were obtained during the railway strike of last August. It is probable that the business men of England could not have secured a better demonstration of the value of industrial transports than during that period, and it is interesting to note that several sections of the British Isles are profiting by the experience gained at that time.

In Glasgow the demand for some new method of transportation has been very real, due to the fact that railway facilities in that portion of the country have been reduced to a minimum. The Glasgow Motor Carriers, a haulage company operating a considerable number of Halley vehicles, is engaged in the cartage of cement from that city to the Partick. It also hauls beer to Motherwell, a distance of some 12 miles; machinery to Wishaw, about 15 miles; stoves from Bonnybridge to Glasgow, and undertakes considerable other work of this character.

First Fire Department Ambulance Recently Installed in Berlin, Germany.

The same thing is true in a measure of Edinburgh, where the Scottish Motor Traction Company often is called upon to make trips between that city and Glasgow, a distance of 37 miles. Some attempt has been made to inaugurate similar service in different sections of England.

KISSELKAR IN JAMAICA.

A member of a large firm dealing in bananas in Jamaica recently returned from Baltimore, Md., bringing with him a three-ton KisselKar truck, made by the Kissel Motor Car Company, Hartford, Wis. This is said to be the first motor vehicle utilized in this work on the island, and the results were so satisfactory that a repeat order for two more machines of the same make has been forwarded to the United States. Other growers are considering the advisability of experimenting with commercial cars, and it is understood that American makers are to find decided competition from British products in the near future, one machine of English make having been ordered already.

MAIL MOTORS IN NEW ZEALAND.

During the past five years the New Zealand government has been employing Albion vehicles, made in England, to good advantage in connection with public service and mail contracting work. So satisfactory have these machines proven that a repeat order has been given for a two-ton vehicle which will be used exclusively in mail delivery.

GERMAN FIRE AMBULANCE.

The accompanying illustrations present the type of motor ambulance recently installed by the fire department in Berlin, Germany. This is the first vehicle of this character in service with a fire department in Germany, and it will answer all alarms, in exactly the same manner as any other piece of fire fighting apparatus. The object, of course, is to provide for the needs of the injured in a possible emergency.

It will be noted that the chassis follows standard lines and is equipped with pneumatic tires of liberal dimensions, thus affording easy riding qualities. The end view shows the interior, and provision is made for carrying at least two patients at a time. The side view indicates the method of placing the patient in the upper cot.

In many respects the vehicle differs materially from those produced in America. This is particularly true of the interior appointments, to which much attention has been paid in the United States. It will be seen that the door covers only a portion of the rear, and while opportunity is afforded for the surgeon to work upon the patient on the way to the hospital, entrance to the apartment is by no means as easy as with American ambulances. Evidently the Germans have something to learn in ambulance construction.

TRACTOR KEEPS BUSY.

An interesting experiment was tried with a Marshall oil tractor in Ireland recently, when the owner set it at work operating a four-foot circular saw, cutting oak and ash planks 20 inches wide, a chaff cutter and an oats crusher, at one and the same time. This work went on continuously for four hours, during which time the machine consumed three pints of gasoline, five gallons and two pints of kerosene and about two quarts of lubricating oil.

SUGAR INTERESTS SEEK MOTORS.

Several of the owners of sugar plantations on the island of Mauritius in the Indian ocean are interested in the availability of motor vehicles for hauling supplies and crops. It is pointed out that the climatic conditions require some special provision of protection from the heat, but in other

Digitized by Google

respects it is anticipated there will be little difficulty in securing suitable transports for this service.

WANT TRACTORS IN AUSTRALIA.

Duncan & Fraser, Adelaide, South Australia, is agent for tractors, particularly of the agricultural type, and has succeeded in placing a number of these. However, it is understood that the farmers throughout this district are anxious to secure a light tractor of the internal combustion type, and manufacturers of this class of vehicles undoubtedly would find a good market in this section.

AGRICULTURAL TRIALS IN ALGERIA.

The directorate of agriculture in Algeria has arranged a competition for agricultural motors in that country from May 26 to June 15. Foreign manufacturers are invited to make entry, and applications should be addressed to the Directeur de l'Ecole d'Agriculture Maison-Carree, Algeria.

TASMANIA NEEDS TRUCKS.

Regular passenger motor service is being operated by two concerns in Tasmania, between Hobart and Launcestown, and it is said that both lines are well patronized despite the railroad communication provided. The success of these vehicles has led to a study of the problem on the part of the owners of some of the fine fruit growing ranches in that vicinity, and it is anticipated that a splendid market will soon be developed for motor trucks in the handling of this product.

SEPARATE SHOW FOR OLYMPIA.

As is more or less well known the people of Great Britain have been compelled to visit Manchester each year in order to acquaint themselves with the new things in commercial vehicles. There was an effort last year to plan a motor truck show in London, but the manufacturers frowned upon the plan. Arrangements are now being made for the 1913 show season, and it is regarded as practically certain that a separate display of industrial transports will be held at Olympia in London during the coming winter.

AGRICULTURAL MOTORS IN URUGUAY.

Plans are nearing completion for an international competition between agricultural motors in Montevideo, Uruguay, during the summer. The Associacion Rural del Uruguay has the matter in charge, and permission has been received from the government to admit all competing machines duty free. In addition the railroads have agreed to transport these vehicles gratis. The entrance fee is $50, gold, for each machine. The entry list was scheduled to close May 1, but as the competition is to extend until Oct. 1, it is probable additional time may be allowed.

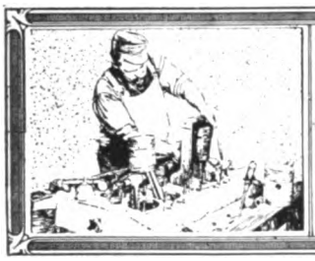
OPENING IN THE FAR EAST.

Great Britain reports a large number of inquiries concerning the use of heavy motor vehicles in the Far East, and particularly in China. The roads are bad and the running costs are extremely high, as has been demonstrated with vehicles now in service, but there appears to be a growing demand for information upon the subject, and it would seem that the near future is to see a market for a satisfactory line of vehicles. Baily & Co., of Hong Kong, has undertaken the importation of chassis and parts, and expects to construct vehicles which will withstand the strains imposed upon them in this country.

POSSIBILITIES IN CEYLON.

The roads in Ceylon are hard and good and a number of motor vehicles are being utilized with satisfactory results. The following extract from the report of the director of public works should prove of interest:

"The roads from Badulla to Passara, Kumbalwellu to Ella, Nanta to Spring Valley and Bandarwela to Liyanguhawela have suffered a good deal from the wear and tear caused by the heavy tractors and trailers traversing them. The results of introducing tractors and trailers with steel tires and axle loads reaching in some cases four tons on an axle, clearly prove that the ordinary macadam surface, even though laid on a stone foundation, will not stand the wear and tear due to the continuous passage of such vehicles keeping to one track along the centre of the way. The increasing traffic throughout a greater part of the island doubtless points to the desirability of an improved system of transports, and the time is arriving when the metalled surface of the roads will require widening.



Interior Construction of New German Motor Ambulance.

"The government has recently ordered for experimental purposes a motor lorry, width five feet six inches over all, with wheels fitted with rubber tires, maximum axle load, fully loaded, not exceeding three tons, and hopes are entertained that vehicles of this type will not only be found suitable for use on many of the existing roads, but also that they will meet the reasonable requirements of the users of the roads."

SEEK AGENCY FOR SOUTH AFRICA.

A representative of a firm in Johannesburg, South Africa, has been visiting England for the purpose of securing an agency for a type of motor vehicle adapted to mining service. It is understood that the management of the mines at Wiwatersrand is extremely anxious to utilize industrial transports in the hauling of supplies and mining products, and those who are producing vehicles of this character would find an excellent market in this section.

MECHANICAL NOTES AND TIPS FOR DRIVERS

WHEEL ALIGNMENT AND TIRES.

In view of the educational campaign being conducted by the manufacturers of tires to correct the evils and abuses to which solid members are subjected, a consideration of the causes of poor efficiency will prove of interest, both to the driver and the owner. The manufacturer has expended considerable sums in laboratory tests in an endeavor to discover the cause of complaint as well as to perfect the compound of the rubber.

During the early days of the commercial vehicle the maker was puzzled to note that while some tires gave satisfaction, others of the same make in service with the same company, developed what appeared to be serious defects. After much study and numerous tests it transpired that the majority of the complaints and tire failures were due to the fact that the shoes had been run on machines the wheels of which were out of alignment.

Operators of the pleasure vehicle watch their tires to note if they show signs of wear due to this cause, but the driver of a mechanical transport equipped with solid members is apt to be careless. This does not arise from a lack of knowledge but rather neglect in regularly examining the cars to ascertain if the wheels are lined up.

It is said that it is a common experience for tire makers to receive a complaint that, with a vehicle on which their shoes have given excellent results, new tires have collapsed at the end of 1000 miles or so, and an examination has, in the majority of cases, proved that owing to some accidental cause, the wheels have been thrown out of alignment. A company manufacturing pneumatics only, issued a pamphlet on this subject recently in which it was pointed out that misalignment of tires reduced their efficiency about 90 per cent. and it is safe to estimate that the value of a solid tire is affected at least 50 per cent. The effect upon the material varies. In most cases the rubber will wear away evenly, but with such rapidity that it is quickly noticed by the driver. In other instances flats are worn on the surface of the tire, creating an impression that the material utilized in its construction is of varied quality.

Effect of Misalignment.

The effect of wheels out of alignment may be realized by taking a couple of coins in the fingers and rolling them along a flat surface keeping them perfectly upright and parallel. It will be noticed they revolve quite easily, but if the coins be set at an angle to each other, although in a vertical position, a considerable amount of side pressure will be noticed. This is what takes place when the wheels of a commercial vehicle are offset or inset from the parallel. The experiment will also convey some idea of how damage to tires is caused when fitted to wheels that are out of alignment, especially front members, as these more frequently suffer from this defect.

As the wheels are always held the same distance apart on the axle, a continual grinding action takes place at the point of contact with the road, this wearing out the tires considerably quicker than would be the case were the wheels perfectly parallel. The extent of the wear may be realized by a simple calculation. If the wheels were offset to the extent of only one inch out of the parallel in a diameter of 32 inches, they would, if free to separate, be over three miles apart at the end of a test of 100 miles. The wear may be illustrated by holding coins against a true grindstone, first parallel and then set at an angle. In the first case the coins will revolve freely without suffering any apparent damage, but when inclined the grinding action will wear away the metal all around the rims.

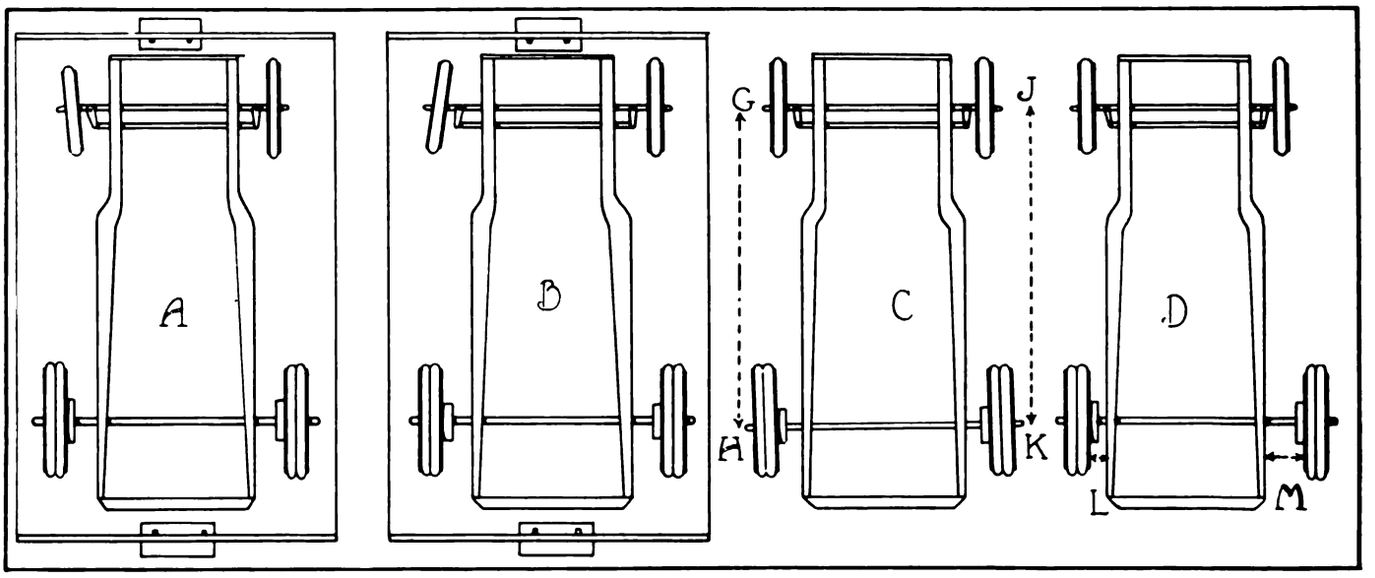
Among the principal causes of wheels becoming out of parallel are: Violent contact with curbstones and carelessly running over large obstructions in the road. Undue lost motion in the bearings of the wheels and steering mechanism are also largely responsible, and whenever there is an undue amount of play steps should be taken to remedy the defect, otherwise damage to the tires is inevitable. Lost motion in the steering gear is the chief cause of flats wearing around the tread of the shoe, this being brought about by the constantly altering direction, unevenness of running, and the twisting effect at the point of contact with the ground. Misalignment is not confined alone to the front wheels, as the rear members may be affected, although this condition is the exception rather than the rule.

Testing the Wheels.

The garage, whether it contain one or a fleet of automobiles, should be equipped with some device for constantly testing the alignment of the wheels and a measuring member may be constructed easily from two pieces of stiff wood battens which should be about 1.5 or two inches square and about nine feet long. In the ends of these members small holes are drilled and two equal lengths of string, cord or twine inserted therein. Care should be taken to make the holes in the wood equidistant, and the ends of the twine in being passed through the holes should be knotted and secured in a suitable manner, so that there will be no variation in the lengths of the cord.

The wooden members should then be placed over the backs of two chairs or suitable rests, so that the lines of string are adjustable in a straight line along either side of the machine. The front wheels should then be jacked up clear of the ground, and the wooden strips adjusted so that the twine on one side is dead straight and equidistant from the edges of the flanges or rims of the front and rear wheels. As there is sometimes a difference in the width of track of the back and front wheels, the actual distance of the twine from each wheel may not be the same, but this is of no great consequence so long as the same difference exists on the opposite side. It is important, however, that special precaution be taken to see that no difference exists on the distance fore and aft of the diameter of each particular wheel. Having made this adjustment, measurements should be taken of the corresponding positions of the wheels on the opposite side, and should there be any variation, it is obvious that the wheels are not parallel and require attention.

Correcting the Faults.



The chief irregularity noted in this test will probably be that one of the front wheels is out of alignment, as indicated at A or B in the accompanying illustration. To correct this fault the tierod should be lengthened or shortened, according to whether the trouble is in front or back of the axle. The tierod is usually provided with an adjustment sleeve by means of which the misalignment may be

Digitized by Google

rectified. If not the rod will have to be removed and remedied. The cost of an adjustment member is slight and should be fitted. The wheels should be adjusted so as to be parallel when they are thrust outward in front as far as any slight play in the steering mechanism will permit, as the forward movement of the car along the road tends to keep them in that position.

It may be that the rear wheels are not aligned; that is, not parallel, and if so it may be caused by a violent collision with some object which has bent the axle. The axle should be removed and repaired, after which the wheels should be tested. Another cause of misalignment is depicted at C and is usually the result of displacement or unequal adjustment of the radius rods. It may be quickly discovered by setting the front wheels parallel with the chassis, then measuring the distances between the ends of the axles and string as indicated at the points G and J on the one side and H and K on the other. These distances should be alike in both cases.

A serious instance of displacement is noted at D and this is detected by measuring the distances from the inside of the rim of the wheel and the chassis frame at points L and M. An examination of the wheels for misalignment should be made every day or at the least as often as once a week, and a more complete test, back and front, at least once a month. By observing these precautions the life of the tires will be augmented and the upkeep of the vehicle reduced thereby.

Depicting the Effect of Misaligned Wheels upon Tires, and a Simple Method of Testing the Members: A, Front Wheel Badly Out of True; B, Similar Condition with Wheel Inset; C and D, Illustrating Unequal Adjustment of Radius Rods and Displacement of Rear Axle.

A SIMPLE WRENCH KINK.

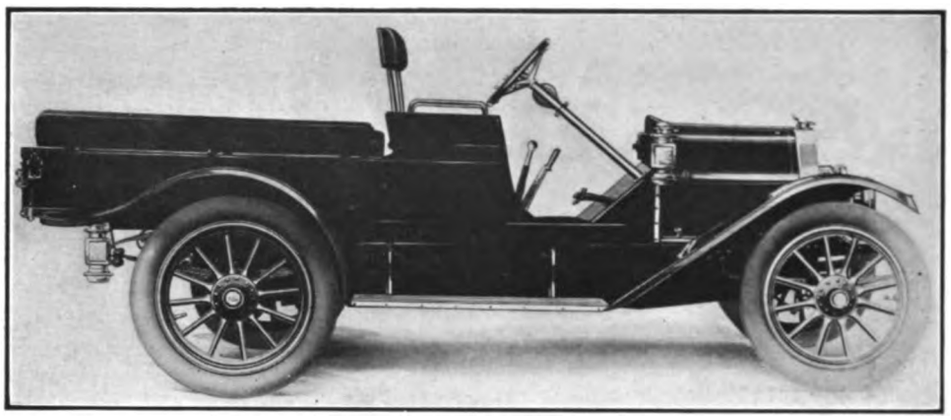
In the event of an adjustment being necessary upon the road and the tool kit is not equipped with the proper sized S wrench, and an ordinary monkey wrench cannot be employed, one of the former type but slightly larger may be utilized by placing a strip of thin metal between the nut to be worked and the jaw of the tool. A few pieces of an old hacksaw blade or metal will prove handy as with these an odd sized nut may be removed or tightened with a standard tool having a larger opening.

WATER IN ACETYLENE PIPES.

Where generators are employed to furnish acetylene for the headlights and the flame flickers, the disturbance as a rule may be laid to water in the pipes. Some types of generators are troublesome in this respect and the only cure is to get a new one or fit the piping system with a trap. The latter may be constructed from a drop elbow. One opening should be closed permanently and the other fitted with a plug. The pipe leading from the generator is cut at its lowest point and the trap inserted in the line by drilling two holes in the elbow and soldering the tubing. Being at the lowest point of the tubing the moisture will collect and may be drained by removing the plug.

PEERLESS WORKS DAY AND NIGHT.

A demonstration of the earning capacity of the commercial vehicle is noted in Fall River, Mass., where a three-ton Peerless truck, made by the Peerless Motor Car Company, Cleveland, O., has been in service day and night for over a year. The machine is employed by the M. Sweeney Company, and two shifts of men are employed. In the daytime it is utilized for general trucking and moving household goods. On Sundays, in the summer, passenger seats are fitted and excursionists are carried to the beaches, etc. During the strawberry season it has regularly carried two truck loads every night from Fall River to Providence, R. I., and the car is used frequently for transporting freight. It has left Fall River at 6 in the morning and taken a heavy load to Lynn, Mass., and after covering 120 miles was back in Fall River at 7 in the evening. It has frequently covered 200 miles in 24 hours. The machine is fitted with a special convertible body. The sides and top are removable and the latter is adjustable to height. After covering 9100 miles the tires were renewed. So well pleased are the owners that a repeat order has been placed with the Peerless Motor Car Company.



MARKET IN SOUTHERN NIGERIA.

It is understood that the people of southern Nigeria, British Africa, are anxious to develop the back country by the utilization of motor wagons. The difficulty of getting goods conveyed to stores located at a distance from the coast is very considerable under the present methods, and it is thought that by cutting a track through the brush it would prove possible to reduce the cost of transportation very materially.

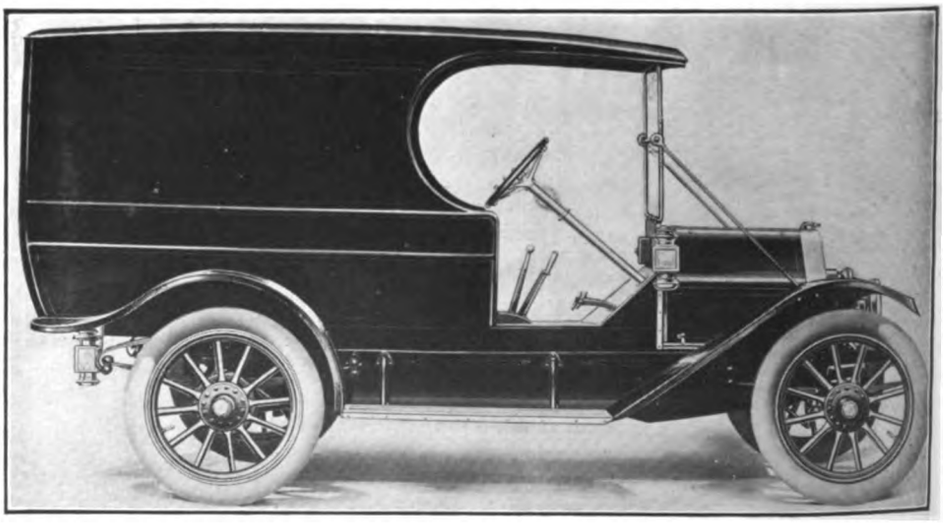
OVERLAND LIGHT DELIVERY WAGON FOR 1912.

INCREASING interest in the light delivery motor vehicle for all classes of service for which such wagons are available, has resulted in the production of numerous models within the past few months. Among the makers devoting their attention to this class of work is the Willys-Overland Company, Toledo, O., maker of the well known Overland line, which brought out a vehicle of this type last year. In making its announcement for 1912, however, it develops that the Overland light delivery is much more interesting than the older design in many ways.

Overland Model 59 Express Light Delivery Wagon for 1912.

It will be remembered that the 1911 model was fitted to a 25 horsepower chassis, the motor having a bore of 3.75 inches and a stroke of 4.5. The transmission was of the improved planetary type, two speeds forward and reverse. Other features differed materially from what is offered in the new chassis.

Two views of the 1912 model are shown herewith, that equipped with an enclosed body being known as the 59 Special, while the other is to be termed the 59 Express. Both are designed to meet the varying requirements of a wide line of purchasers. The Special is easily accessible from the rear, two large doors, extending the full height, being fitted. The Express also is of ample dimensions, and each is handsomely finished, the former in maroon with black trimmings, and the latter in Overland blue and gold. As has been indicated, the chassis is the same for both models, and is rated at 800 pounds.



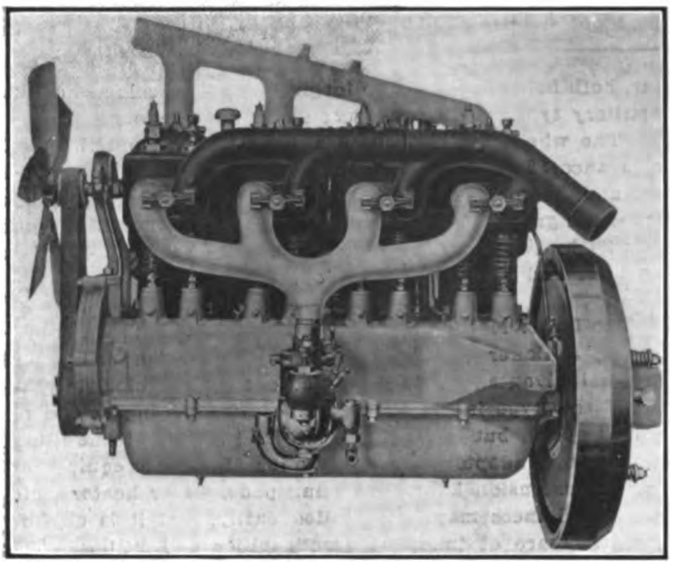
The reputation of the Willys-Overland Company in the production of pleasure automobiles is too well known to need comment. It is sufficient to say that the same careful workmanship and attention to detail is evidenced in the construction of the light delivery wagon. The best of materials is utilized throughout, and particular endeavor has been made to produce a vehicle which shall withstand severe usage.

The motor is a four-cylinder, four-cycle, water-cooled unit of the L head type, with all valves on the left hand side, where they are operated from a single camshaft with integral cams. The cylinders are cast separately of a high grade gray iron and are arranged vertically under a hood. The bore is four inches and the stroke 4.5, giving a horsepower that is rated conservatively at 30 by the maker. The speed range is from 4.5 to 50 miles an hour, and extended tests have demonstrated that the car will operate successfully on an average of 20 miles to a gallon of fuel.

All pistons and rings are accurately ground to size and fitted with extreme care. The cylinders are supplied with ample water jacketing surface, and particular attention has been paid to the matter of cooling, which is by thermo-syphon. The radiator is of the honeycomb tubular type, supported on either side by trunnions which take up all road stresses. The special design is with reference to securing the minimum amount of wind resistance. The six-bladed adjustable fan is hung from an arm of the crankcase, extended upward and is driven by belt from the crankshaft. The maximum temperature of the water is held by the maker to be 198 degrees.

The crankshaft is of a special grade of alloy steel, hardened and ground. The bearings are of liberal area, five in number, plain, die cast, and very accurately fitted. Extreme care has been taken in the matter of fitting the inlet and exhaust manifolds, to permit the easy ingress and egress of all gases. The camshaft is of a selected quality of steel, fitted with three bearings of the same material and design as those of the crankshaft. The camshaft is hardened and ground to limits, thus insuring the size of the bearings and the certainty of valve timing.

Lubrication is by a force feed oiler to the cylinders with constant level splash in the crankcase. The system has a capacity of one gallon. Ignition is by jump spark, utilizing a Splitdorf dual magneto and dry cells. The carburetor is of the float feed type, and the design has proved very efficient in service. The gasoline capacity is 14 gallons. Ignition and carburetion are controlled by levers located on the steering post.



Overland Model 59 Special, a Satisfactory Utility Vehicle.

The clutch is a cone member with a woven asbestos and wire facing which is heat proof and will not char. This en-

Digitized by Google

gages with the cast iron inner surface of the flywheel.

The transmission this year is selective, permitting three forward speeds and reverse. The following gear ratios are provided: One to one for the high, 1.55 to one for the intermediate, 2.57 to one for the low, and 3.3 to one for the reverse. This is located as a unit with the rear axle system, and F. & S. annular bearings are employed throughout. Drive is by shaft, through the torsion tube to the bevel gear on the live rear axle, which is of the semi-floating type and equipped throughout with Hyatt roller bearings.

Left Side of Overland 30 Horsepower Motor.

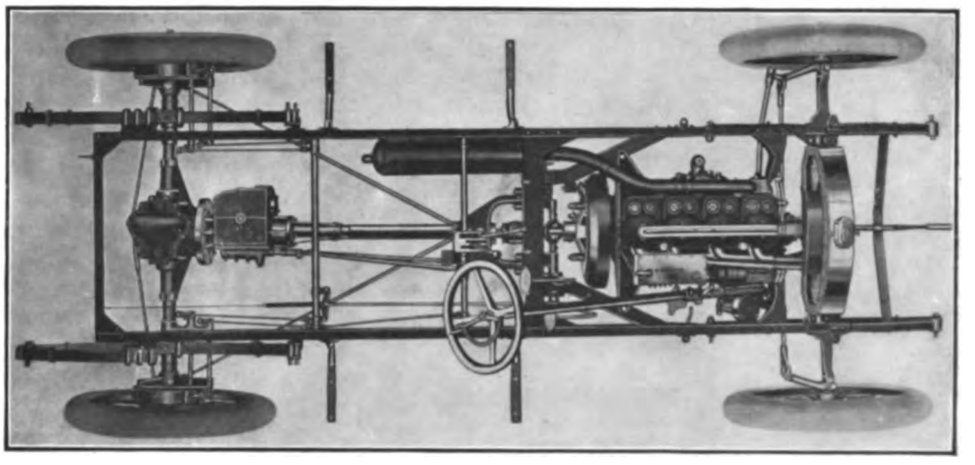
The frame is of channel section cold rolled steel. The front springs are semi-elliptic, 36 inches length and 1.75 inches width, while the rear members are three-quarters elliptic and of the same dimensions. The front axle is an I beam section, drop forged, the wheels running on ball bearings. Service brakes are expanding on the rear hub drums, controlled by pedal; the emergency members, contracting on the rear wheels and controlled by lever. The brake drum diameter is 10 inches with a width of 2.5625 inches.

The wheelbase this year is 106 inches, as compared with the 102 inches of 1911. The tread is 56 inches. Wheels are of the artillery wood type, with 12 1.5-inch spokes and 12 bolts to each wheel. Tires are pneumatic, 33 by four inches, all around.

Special mention should be made of the control system. It will be noted from the accompanying illustrations that the central position of levers is favored, this being of particular interest to the operator of a delivery wagon, where it is desirable to have easy access to the driver's seat from either side of the vehicle. The steering post is on the right. This is fitted with a worm and gear type of steering mechanism and a 16-inch laminated wood hand wheel. The gears operate on plain bronze and ball thrust bearings, and the steering knuckles are of Tobin bronze, eliminating all danger from leakage.

Every effort has been made to provide for a satisfactory delivery wagon from every viewpoint. To this end the dimensions of both bodies are very liberal. The length of the floor in the Special model is 60 inches, and the width 43. The height from the floor to the top is 53 inches. This is sufficient to permit of carrying a full load of light weight products, and makes the car particularly desirable by florists, grocers, jewelers, etc.

In the Express, the length of the floor is 67 inches and the width 42. The height of the sides is 10 inches, and the width of the side wings six inches. The utility of this equipment will be apparent to those who are seeking a wagon designed to provide ample carrying capacity for all classes of merchandise.



With each of these bodies, the company furnishes two gas headlights, two oil side lamps and one oil tail lamp, generator, full set of tools and tire repair kit. There is little doubt that both of them will meet with ready acceptance by a large number of concerns who have been awaiting the arrival of a light delivery wagon with plenty of reserve power and designed to meet every need.

INTRODUCING MOTOR PLOW.

California farmers are being converted to the use of motor propelled agricultural implements, the Hackney Manufacturing Company, St. Paul, Minn., maker of Hackney plows, having established a Pacific Coast branch at Los Angeles. The plow is the invention of Leslie S. Hackney, president of the company, and is 14 feet in length and six feet five inches wide. It is equipped with a four-cylinder, four-cycle motor, having a five-inch bore and six-inch stroke, and its maximum is obtained at 800 revolutions a minute. The machine can be utilized for many purposes. By means of a side lever the blades may be raised clear of the ground and the device employed as a tractor. It also can be used to saw wood and perform numerous other duties about the farm. The plow is being demonstrated to the farmers.

GOODYEAR TIRE PRODUCTION.

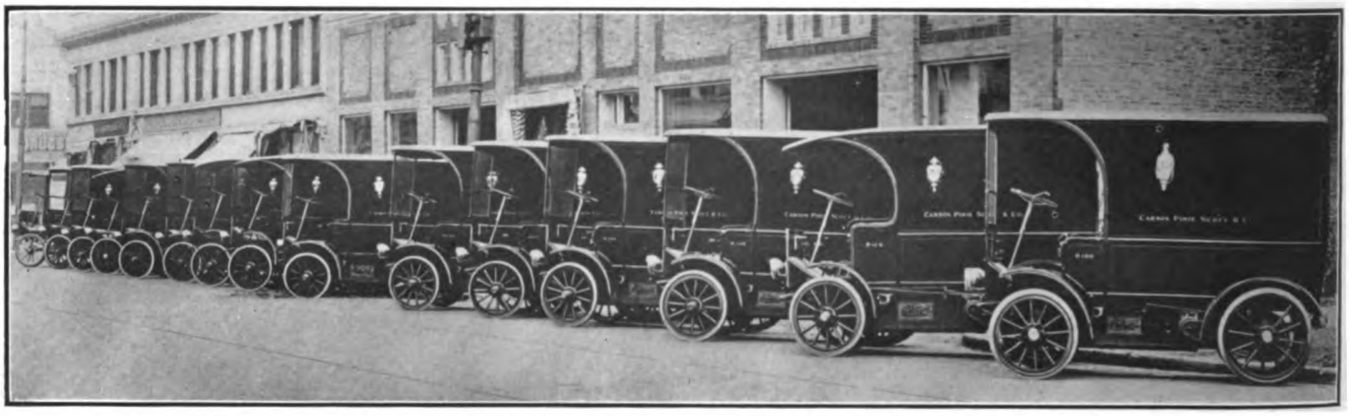
In celebrating its birthday recently, the Goodyear Tire & Rubber Company, Akron, O., maker of Goodyear tires, enlarged its production facilities so as to increase the daily output of 4000 tires to 5000. This has particular reference to the shoes for pleasure vehicles, but it is interesting to note that the concern is now manufacturing between 400 and 500 solid motor truck shoes a day. This means that during the year 1912, 7,500,000 pounds of material will be needed to meet the requirements of this concern in this particular field. The daily output is sufficient to equip 150 vehicles. C. W. Martin was recently appointed manager of the motor truck department of the company.

Overland Light Delivery Chassis Is Remarkably Simple in Design.

Digitized by Google

ELECTRIC VEHICLE BREVITIES

The value of the light capacity electric delivery wagon is conceded by a large number of department stores, who have installed this type of vehicle. The usual method has been that of thoroughly testing out one or two cars, and when these have had opportunity to demonstrate their practicability increasing the equipment along lines which experience has dictated is best.



In an accompanying illustration is presented 15 of the 22 1000-pound Detroit electric wagons, made by the Anderson Electric Car Company, Detroit, in service with Carson Pirie Scott & Co., Chicago. This fleet has been in operation for more than a year and has given entire satisfaction in covering various routes. These 15 are garaged in South Chicago and operate in that territory, while others are stationed in Evanston and Highland Park. A few of the machines owned by the company are of one ton capacity. The entire fleet handles merchandise brought to the respective territories by larger cars.

The light vehicles are equipped with Edison 60-cell batteries; in fact, it may be stated that this type of battery is used exclusively in the Detroit electric cars. The motor is the firm's own make, a series wound type, in which varied load and road conditions are handled without undue increased current consumption. Copper and iron are used in such quantities as to withstand overloads for long periods without excessive heating. The brushes are well mounted and of liberal area. The normal voltage is 70 and the ampere rate 30 at 1300 revolutions a minute.

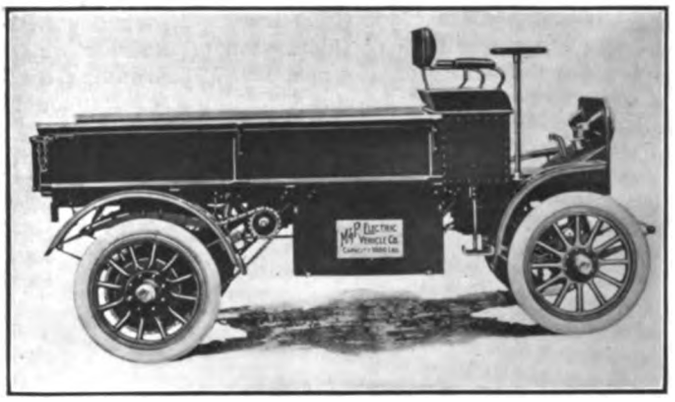
The controller is of the continuous torque, drum type, also made by the Anderson company. Plenty of contact area is afforded, the contact fingers being held under tension by laminated springs. The reverse switch is of the improved laminated type, mounted with the controller. An interlocking device of simple construction eliminates the possibility of the driver "bucking" the motor, it being necessary to bring the controller to a neutral position before changing the current direction. Oilers are provided at all important points.

The expanding band type of brake is employed, both on the wheels and countershaft. Springs are semi-elliptic front and rear, resting on large dimension axle seats, through which are drilled holes for the clips. The frame is of channel, angle and T steel. All joints are hot riveted. Sheet steel is used for the battery and motor compartments, this being riveted to the frame members and battery supports. The front axles are I beam, and the rear rectangular, both being special drop forgings. All wheels are of the artillery type, made from second growth hickory.

The wheelbase is 80 inches, the tread 56 and the road clearance 12. The length of the body is 129 inches, width 66 and height, 90, the platform being located 30 inches from the ground. Tires are solid, 32 by 2.5 inches in front and 34 by two inches in rear. The rated speed is 14 miles an hour and the mileage, loaded, about 50.

A Portion of the Fleet of Detroit Electric Light Delivery Wagons Owned and Operated by Carson Pirie Scott & Co., Chicago.

The Baker Motor Vehicle Company, Cleveland, O., is producing a Baker electric ambulance, for which is claimed unusual advantages. It is pointed out that an electric vehicle of this type is not only capable of travelling at the required speed, but is sanitary, safe and silent. In addition, it is readily adaptable to all manner of electric equipment, such as extension lamps, warming pads, water heaters, etc. Such appliances may be installed easily, and it is obvious that they are of immense practicability and utility. The current which they consume is inconsiderable and may be supplied from the battery which runs the car.



When equipped with pneumatic tires, the Baker ambulance has a speed rating of 18 miles an hour. The body rests on a 1000-pound chassis. The interior arrangement is such that two patients may be carried at a time, with plenty of room for two attendants. One patient is placed on a rigid frame cot which rests in a runway on the floor, while the other may be carried in a stretcher suspended from a unique spring hanger. The interior finish is in white enamel, and all cracks and crevices in the floor and sides have been eliminated to facilitate proper sanitation.

The Continental Car & Equipment Company of Highland Park, a suburb of Louisville, Ky., has an electric motor truck proposition under consideration. As a matter of fact it has two cars in operation. The first model was a three-ton vehicle which left the shops a short time ago. This is being tested out with a view to interesting capital, and it is intimated that it may be decided to manufacture the product in one of the cities in the East. Much interest has been aroused in the plans of the company, because of the fact that it is well known as a producer of contractor's dumping cars, now in use in all parts of the world.

The M & P Electric Vehicle Company, Detroit, Mich., is a new concern which brought out a 1000-pound car during the recent Chicago show. The concern has capital of $50,-

Digitized by Google

000 and the officers are: President and general manager, Charles L. Pepper; treasurer and sales manager, M. C. Merriman; secretary, Burton Grandy. The product is presented in accompanying illustrations, one of which shows

The New M & P 1000-Pound Vehicle Produced in Detroit.

the chassis equipped with an open express body and the other with enclosed delivery.

The motor, an 80-volt Westinghouse unit, is located well forward, the drive being through a propeller shaft to a countershaft through the usual bevel gears enclosed in a housing which also contains the differential, and thence by side chains to the rear wheels. In order to make use of the propeller shaft the battery, a 40-cell Gould, is divided, each section of 20 cells being enclosed in its own box and hung on either side of the car. The location is such with reference to the mudguards and other parts of the machine, that nothing interferes with easy access to the boxes for removal and replacement of cells.

The controller is almost directly over the motor, which is under the seat, and as the battery boxes also are close to the motor, all wiring is short. In addition this makes for easy location of the fault, in case trouble should occur. The motor is readily accessible through the floorboards and the controller through the front boards of the seat.

The main chassis frame is of three-inch channel steel with ends and cross pieces of the same stock. The springs are semi-elliptic front and rear. Both axles are of Weston-Mott manufacture, the front member being I beam and the rear, square forged shaft. The jackshaft also is a Weston-Mott. Wheels are 32 inches in diameter, built according to the S. A. E. standard and fitted with three-inch solid tires. Pneumatics may be had as an option, however.

The wheelbase is 100 inches and the tread 56. The loading space with the express body is 80 by 42 inches and with the enclosed body, 80 by 42 by 56. The rated speed is 12 miles an hour and the mileage 50.

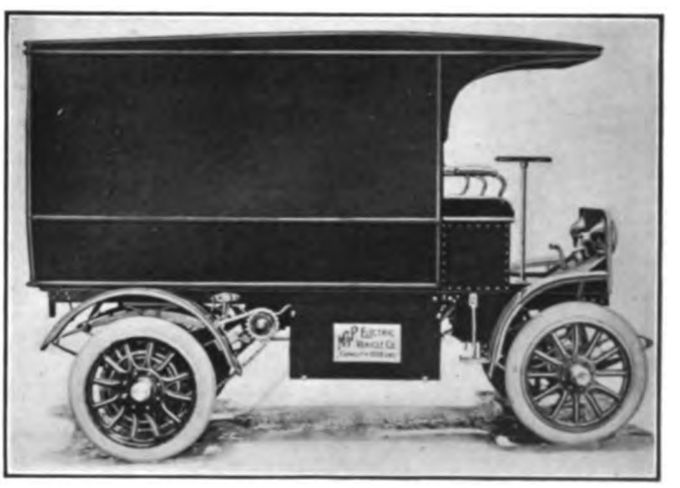
★

The combination of the old Electric Vehicle Company of Louisville, Ky., with the Kentucky Wagon Manufacturing Company of that city, under the terms of which the former concern becomes the electric truck department of the latter, is expected to result in a rapid development of the Urban 1000-pound car made by it. Henry B. Hewitt, president of the Electric Vehicle Company, becomes general manager of truck department. Louis Ruthenburg, superintendent and engineer, and W. C. Knopf, electrical engineer. In addition to the car named, plans are now under way for the construction of three new models which will be rated at one, two and 3.5 tons, respectively.

The present capacity of the plant is 150 cars a year, but the company stands ready to increase the equipment and enlarge the capacity as the demand is developed. This is only one of the advantages of the combination, however, inasmuch as the Kentucky Wagon Manufacturing Company, before its absorption of the electric truck concern, had begun to specialize in the production of motor truck bodies of all types. This will give the purchaser unusual facilities for securing that which will best meet his needs.

Among the features which have been added to the Urban wagon are several devices which are calculated to extend its field of usefulness. These include a blower, a pump, incandescent lamps and other equipment operated by current from the batteries of the car. For emergency work, such as is undertaken by the Kentucky Electric Company of Louisville, which owns one of these vehicles, involving the entrance to manholes, which frequently are filled with noxious gases, the car promises to be invaluable, as it can be utilized to blow out the foul gases, light up the working spaces, etc.

★



C. L. Morgan, sales manager of the electric division of the General Motors Truck Company, Detroit, maker of G. M. C. cars, recently superintended an electric vehicle test which will compare favorably with any devised by makers of gasoline machines. During one of the heavy snowstorms of early April, one of his men drove a three-ton G. M. C. truck from Pontiac to Detroit, carrying a full load and running within 20 per cent. of its full rated capacity. The roads were in decidedly poor condition, and the snow was drifting badly, piling up in some places as high as three feet. Despite these difficulties, the truck made good time and covered 26 miles.

★

Those concerned with the delivery of United States mail are becoming more and more convinced of the special advantages presented by electric wagons. Those which have been placed in service in many cities throughout the country, have demonstrated their efficiency under every test, and it appears to be a foregone conclusion that the Post-office Department will decide upon the extension of their use as opportunity affords. It is not so much a question of load or mileage capacity which interests government officials in this field, but the most essential feature is the ability of the electric to start and stop readily. In the collection of mail it is necessary to make frequent short stops, and there is a real demand for a car which will be certain to start at once without cranking and other tedious preliminaries.

★

Upon recommendation of Julien A. Halford, a well known English engineer, H. G. and F. G. Sharp of Toronto, Can., practically have decided to inaugurate a motor 'bus

M & P Electric Chassis Equipped with Enclosed Delivery Body.

service in that city. It is understood that the type of vehicle determined upon is a double-deck electric car with seating capacity for 50 persons. The plans call for the purchase of no less than 50 machines.

Digitized by Google

The General Vehicle Company, Long Island City, N. Y., maker of G. V. electric trucks, has been studying some of the reasons for the large installation of its vehicles, included among which may be mentioned the 21 operated by Tiffany & Co., New York City, which have been in use 10 years; the 50 owned by the Anheuser Busch Brewing Company; the 48 belonging to the Peter Doelger Brewing Company, which has the finest reinforced concrete electric garage in the world; the 72 operated by the Jacob Rupert Brewing Company; the 38 owned by the R. H. Macy Company, and those numbering 100 or more in service for the Adams Express Company and the American Express Company. It finds the answer in the single word, "simplicity." The investigation is summed up as follows:

"One of the potent reasons for the success attending the introduction of the electric truck is its extreme mechanical simplicity. A simple series wound motor, practically of the same character as those used in the street cars of every city and town, is used to drive the vehicle. A Morse silent chain conveys the power to the countershaft, and roller chains to either side carry the power to the rear wheels. So simple is this power plant that it is seldom, almost never, out of order.

"A small lever is pushed forward by the driver's left hand, and the car moves forward; the further forward it is pressed, the faster the truck goes. To reverse the vehicle, the lever is pressed back, and the car run backwards. The steering wheel and post are rugged and simple. A pinion and sector give motion to a bell crank which through rods operates the steering knuckles on which are the front wheels. The whole operation is so simple that a teamster who understands the rules of the road, makes an efficient driver after a few hours' experience.

"Another, and perhaps one of the greatest reasons for the success of the electric vehicle, ranking second only to the improvements in construction, is the intelligent way in which it is sold. In the past they were sold to anyone who wanted to buy, and for any class of work. The result was many impractical applications. Today the selling engineer looks over each proposition, and if one is presented that is not practical for the electric to handle, the customer is advised to use horses or some other form of motor vehicle.

"This leads to the suggestion that the transportation superintendent should cease to think of the electric as a competitor of the gasoline driven machine. The true efficiency of the latter commences where that of the electric ceases. The electric should not be sold for the gasoline work, the long, straightaway hauls with few stops, nor should the gasoline be placed in the electric truck field, the short and medium runs with many stops. Whenever either form is operated in its wrong sphere, failure is sure to result."

★

The Baker Electric Company of Michigan was incorporated at Detroit, April 3, with the following officers: President, J. Caldwell Walker, Detroit; vice president, R. C. Norton, Cleveland. O.; secretary and treasurer, William C. Burnett, Detroit. This is to be a direct factory branch of the Baker Motor Vehicle Company, Cleveland, O., maker of Baker electric cars. The new salesroom will be located in the heart of the automobile district on Woodward avenue, and a complete line of pleasure and commercial vehicles will be carried.

★

William H. McLellan, a salesman at the Boston branch of the R-C-H Corporation, Detroit, recently took a 1000-pound Hupp-Yeats delivery wagon over the road from Providence, R. I., to Boston, carrying a load of 750 pounds, in 4:15:00. The distance covered was 52 miles according to the speedometer. In many respects this was a remarkable demonstration.

While it is generally conceded that the legitimate field of the electric is in city and suburban work, it will prove of interest to note that this trip was over country roads, some of which were of macadam it is true, well supplied with hills and in a condition at this season of the year which would tax the ability of any machine. The running time is worthy of comment as well. The Hupp-Yeats undoubtedly will meet with decided favor in New England, if it is able to make such trips with reserve energy, as is said to have been true in this instance.

★

"That the gasoline chassis is popular today," says C. L. Morgan, sales manager of the electric vehicle division of the General Motors Truck Company, "isn't to the discredit of the electric. They both have their distinct fields, but do not think for a minute that the electric truck makers have not been progressive, for they have worked just as hard to secure the serviceable vehicle as the other branch of the industry.

"Their popularity will increase with a better knowledge of their advantages. Take for instance the G. M. C. electric, embodying as it does, two features that are as important mechanically as any improvement made on a gasoline chassis. We have eliminated the chain which is commonly used for the first reduction from the motor to the countershaft.

"Another vital point in the electric chassis construction is the position of the batteries. We have placed them where they are accessible, above the frame and under the driver's seat. This location eliminates time, labor and the trouble of disconnecting and drawing out the batteries for inspection, and the difficulty of caring for them through trap doors in the floor."

★

The General Vehicle Company, Long Island City, N. Y., announces that its plant is now working to full capacity and the construction of a new factory is under advisement. Over 100 G. V. electric trucks were shipped during April, and there are many orders on hand for delivery as late as next November. Prospects are also bright for many new orders from all sections of the country, and some of these are expected to reach as high as 30 from new customers.

The bulk of the General Vehicle business, however, comes in the form of repeat orders. The company is now reaping the reward for standardization and conservative selling methods put in force five years ago. That it pays to have high standards in building and selling motor trucks is evidenced by the growth of this pioneer manufacture. It is held by this concern that it is better to sell two trucks to a customer and have them adapted to his work than to make sales indiscriminately and secure few if any repeat orders.

TRUCK REPLACES SPUR TRACKS.

The Groton & Stonington Street Railway Company, Groton, Conn., is planning the purchase of a truck for the purpose of making deliveries from its express cars, this being necessary owing to a rapidly increasing business. The company handles considerable freight for manufacturing concerns and the latter have requested the building of spur tracks to their plants. By installing a machine for this work it is figured that considerable expense may be saved and the service improved. It is proposed to run the automobile to Mystic in place of the usual cars. A trial was given of an automobile and the demonstration was successful in every particular. The installation of such a service will be a great benefit to the business men and other patrons.

RECENT MOTOR VEHICLE PATENTS

De Fazi Piston.

Fulvio De Fazi, Providence, R. I., assignor of one-half to William D. Blossfield, has been granted a patent for a gas engine piston, which presents unique features inasmuch as it dispenses with the usual wristpin. The head of the piston carries a thrust block which engages with the ball end of the connecting rod. The block is adjustable, being screwed into a larger, similar member and is provided with a set screw, the purpose of which is to take up lost motion. The ball and socket members are lubricated by means of an oil duct which leads from the side of the piston to the top of the ball portion of the connecting rod. It is claimed by the inventor that perfect alignment is secured and that wear upon the walls of the cylinders and piston rings is reduced to a minimum by the ball and socket device.

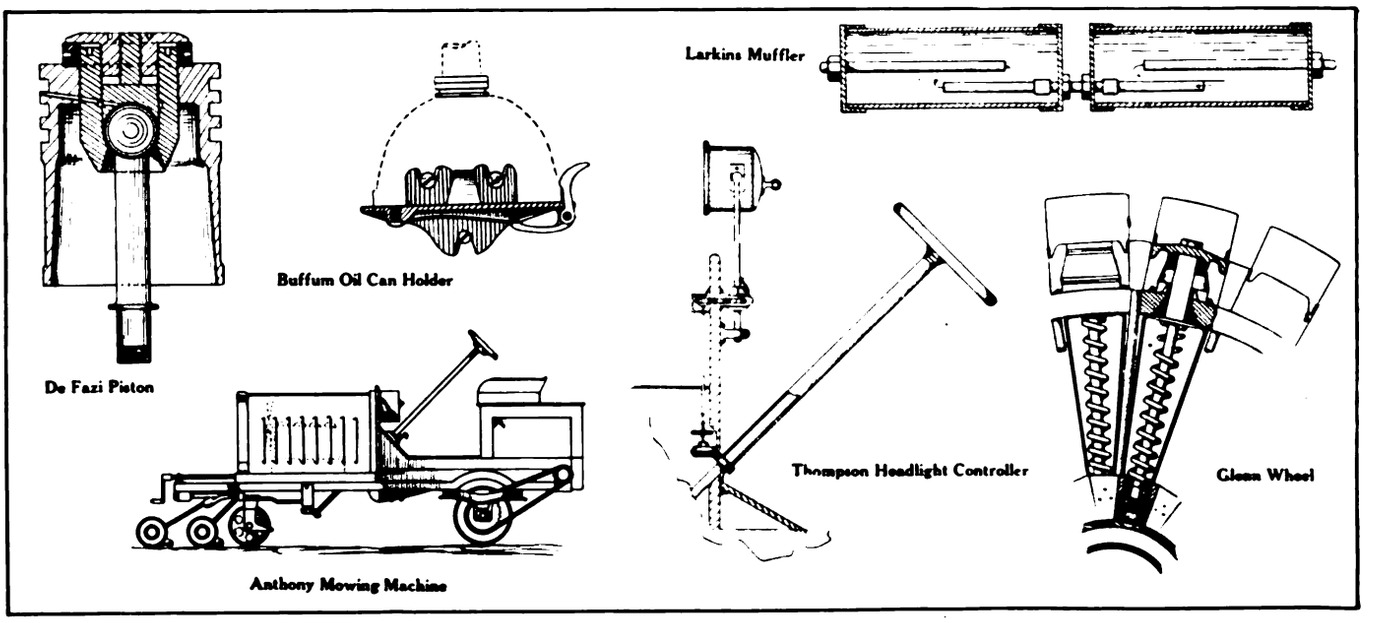
Buffum Oil Can Holder.

Frank Washburn Buffum, Louisiana, Mo., has been granted a patent for an oil can holder which comprises a metal base having integral jaws and carrying a boss and lugs on the underside. A pivotally mounted jaw is fitted which exerts a downward pressure, forcing the member into engagement with the lower edges of the font of the oil can. The latter is engaged or released easily, the inventor claims.

Larkins Muffler.

Herman H. Larkins of Princeton, Ky., has patented a muffler which differs from those of usual construction, inasmuch as the device is made in two sections. It consists of two cylindrical members with ends closed, with the exceptions of the inlet and exhaust portions and connecting tube. The drums are separate but connection between them is maintained by a tube which extends about two-thirds of the way into the interior of each cylinder. Above this piping are placed the inlet and exhaust tubes. The gases enter through the latter and expanding, pass through the larger tube into the second drum where the operation is repeated before the burnt products escape into the open air.

Anthony Mowing Machine.



Wendell P. Anthony, Eddystone, Penn., assignor to William Simpson & Sons, Philadelphia, has patented a mowing machine propelled by an internal combustion motor. It is similar to a motor car with the exception that the forward truck carries the grass cutting mechanism which comprises three independent rotary cutters operated through universal joints. The arrangement of the cutters is such that the middle member cuts a swath between those of the others.

Thompson Headlight Controller.

Various devices have been invented for swivelling lamps of the bonnet type, but a new departure is noted in the invention of Francis E. Thompson, Arlington, Mass., who has been granted a patent for a device controlling the dash type of searchlight. The member is pivotally mounted on a shaft carrying a gear in mesh with another pinion and a second shaft actuated by the steering column. When the steering wheel is rotated, motion is imparted through the gears and shafting to the lamp, the latter turning proportionately and in the same direction as the front wheels.

Glenn Wheel.

A vehicle wheel which the inventor claims has resiliency although of the solid tire type, has been patented by Edward A. Glenn, Chicago. This consists of a series of block-like tread members mounted on a rod and coil spring arrangement. Flanges are provided on the under sides of the tread portions and these are of different diameters and adapted to telescope within each other.

Some of the Latest Inventions Applicable to the Motor Truck Industry, Including Novel Gas Engine Piston, Headlight Controller, Muffler, Mowing Machine, Etc.

CORRESPONDENCE ON PERTINENT SUBJECTS.

Mr. Swinehart of the Republic Rubber Company Discusses the Question of Guarantee for Truck Tire Equipment from an Entirely New Viewpoint.

ANY discussion relative to the use of tires is of deep concern to all branches of the commercial vehicle industry, and particularly to the owner. The following letter takes up the matter from a somewhat different viewpoint, and the arguments of the writer should prove of interest:

Editor, MOTOR TRUCK.

Sir:

I contend that the guarantees made on motor truck tires at present are exorbitant and unjust. Years ago the user was entitled to a service guarantee for the reason that efficient fastening devices had not been developed. The majority of motor trucks were under-tired, and the spring suspension was poor, with the result that the user had to pay dearly for tire service, but of late tire construction has been improved to a degree that warrants users securing a satisfactory service, providing he purchases from a reputable company, and his driver uses fair judgment in loading and driving.

The three parties vitally interested in truck tire guarantees are the tire manufacturer, the truck manufacturer, and the truck user. I will not take into consideration the truck dealer, as he is really a part of the selling organization of the truck manufacturer, neither will I consider the driver, for the reason that he is under the direct control of the user.

B. C. Swinehart, Sales Manager, Republic Rubber Company.

The seven elements governing the length of tire service are: Material, workmanship, equipment, load, speed, road conditions and the driver, or his method of driving. In assigning to each party interested such of these elements as he may be responsible for, I intend to show that the user is really more responsible for the amount of service that can be obtained from truck tires than either the tire manufacturer or the truck manufacturer.

With regard to material, exhaustive tests of material of different characters have been made during past years, with the result that today tire manufacturers are using compounds which in many cases are much better than those used eight to 10 years ago. Even the prices are lower. This has been accomplished only by continual experimenting and testing of various stocks under the most severe conditions.

The workmanship on truck tires has been greatly improved. The designs of the tire have been changed so as permit their carrying heavier loads. The systems of fastening devices and rim design for proper application of tires have been improved, so that it no longer requires hours to make tire changes, and the tire is held more securely in the rim. All this has been the work of careful experts, who have been devoting years of work toward reducing tire cost a mile.

The truck manufacturer is largely responsible for the equipment, as regards size of tires. In the past I have found many cases where the truck manufacturer turned out trucks which were under-tired. His responsibility in this, however, is limited, owing to the fact that many users when buying trucks specify the size of tires which they consider will best accomplish their work. The truck manufacturer is only partly responsible for the loads carried. In cases where one kind of freight only is to be hauled, he can so design the body as to permit the carrying of a normal load only. However, in cases where mixed freight is hauled, he has little, if any, control over the loads that will be hauled by the user.

He is to blame to a degree, however, for the reason that often in making demonstrations he will carry excessive overloads, in order to assure the customer that he has a good strong truck. In a recent case, which came to my notice, a truck manufacturer hauled seven tons of freight a day for two weeks, upon a three-ton truck, in order to demonstrate to the prospective purchaser that his truck would do the work satisfactorily. You can readily realize the strain which was thrown upon the tires. Often truck manufacturers will publish photographs of a new model of truck carrying 100 per cent. overload, yet in selecting their tire equipment they provide for only a normal load.

The speed at which trucks are operated is controlled to a certain degree by the design of the truck, but the truck manufacturer has little control of this feature after the truck leaves his hands. Excessive speed, under fair conditions, rests more largely with the driver of the truck.

I believe that the consumer, through the agency of his driver, is really responsible for loads carried. Overloading can be accomplished by a misplacing of the load; that is, in cases where heavy castings are hauled, it is not fair to place these at the extreme rear end of the truck, neither is it fair to place them to one side, as this will cause the tires nearest the load to receive undue strains. Just as much care should be exercised by the driver in placing his load properly as he should use in not overloading the truck. Tires are designed to carry a certain load, and the factor of safety in design is very small. When a tire is overloaded it will break down under the load. One of the first indications is the loosening of the tire from the rim. This will often go unnoticed until long after the time when the tire received the abuse.

Speed is one of the most destructive elements entering into tire service, due to the excessive heat generated in the tire by internal friction. A truck tire designed to carry a stated load at 12 miles an hour, will give a much smaller part of the required service, if it is forced to carry the same load at a speed of 20 to 25 miles an hour. Driving a truck at excessive speed has the same evil effect that overloading it has, in the event of striking a raised car track, or other obstruction in the street. The blow which the tire receives is increased far beyond its carrying capacity, and the result is a bruise, or rupture, which in time will develop into a broken tire.

The truck user is really responsible for the road conditions, for the reason that he should instruct his driver to pick out the best route as regards road conditions, even though the distance may be greater. Economical tire service can be obtained even over bad roads, if the driver will use judgment in the speed at which he operates. There is a tendency among drivers to take the shortest route, irrespective of the road conditions, feeling that the tires are guaranteed for a long service. The result is they will drive over streets strewn with broken bottles, old iron, stones, etc., which are certain to cut the tires, eventually resulting in the tires breaking up, or going to pieces. One case which recently came to my attention was that of a large packing company operating several trucks. It permitted its drivers to take a short cut over four railroad tracks which were not planked for crossings, in order to save a detour of one block. They maintained that the tires were guaranteed to cover a given number of miles, and they could not pick their roads as they must make a certain number of trips a day.

In considering the driver, I feel that he is really responsible for 60 per cent. of the tire trouble experienced by truck users. He is directly responsible to the user, and should work for his interests to the extent that he should spare the truck and tires as much as possible. A careful driver can get from three to six months more service from a set of tires than a careless driver, even though both cover the same route, and carry the same loads. Spinning the driving wheels when starting, or sliding them when stopping, does more damage to the tires than 16 to 25 miles of normal service. Driving in car tracks throws all the load on one side of the tire, and in the case of dual tires, one side has to carry all the load, resulting in an excessive overload for that tire. A careless driver can ruin the best set of tires made in 2000 miles, by neglecting the usual instructions for operating.

The guarantees in force today are really interpreted as a guarantee that the tires cannot be destroyed in less than 8000 to 10,000 miles, as the case may be. It is true that tire manufacturers impose certain restrictions as regards overload, speed and driving in car tracks, but they have no means of learning to what extent the tire has been abused. A wornout tire will not indicate, except in the most exaggerated cases, the kind of treatment it has received, with the result that adjustments are demanded and received by the users while the tire manufacturer has no way of protecting himself, unless he goes to the trouble of inspecting the records, if such are kept, of loads carried, distance travelled, and trips that the truck makes. This would prove to be a very expensive plan, even if it were possible. In most cases, proper records of truck service are not kept, and the user simply guesses that he has not had sufficient service. Recently a user claimed that he was not operating his truck more than 20 miles a day. I took the trouble to drive over the route which he made in the morning and finished at about 2 in the afternoon, in order to check the distance. That route alone measured 32.5 miles, and he usually made short trips during the afternoon, so that his tire mileage a day was nearer 40 than 20.

The tire manufacturer is responsible for workmanship and material, and has spent thousands of dollars in developing and improving both the construction and the material used, and

Digitized by Google

I am satisfied that all reputable manufacturers are honestly trying to give dollar for dollar in tire service The guarantee, from the maker's standpoint, is simply a wager that the tires will run a stated number of miles. If the driver prefers to have them do less, he promptly sets to work to destroy them in the shortest possible time.

The truck manufacturer maintains that a long guarantee on tires aids him in selling his trucks, as he can figure upon a stated tire cost a mile. This, perhaps, is true, to a certain degree, but as the truck manufacturer assumes no responsibility in connection with tire equipment, I feel he should leave this matter largely to the parties most directly interested—the tire manufacturer and the user. The truck manufacturer is only indirectly responsible for the service that tires will give, for the reason that the matter of loads, speeds and road conditions, are entirely in the hands of the user, through the agency of his driver.

The truck user is responsible for more of the elements conducive to an economical tire service than the tire manufacturer and the truck manufacturer together. He has direct control over loads, speed, roads traversed, and the driver. Upon these four elements depend more than 75 per cent. of the responsibility for the tires not giving the average service. I have seen really poor tires give a fair service, where care was used in driving. On the other hand, tires of the best workmanship and material were ruined in a comparatively short time, due entirely to the negligence displayed in their use. Since the elements surrounding the use of the tires play such an important part in determining the length of service, it would seem only just and fair that the user should assume his share of the responsibility, and not demand that the tire manufacturer assume the responsibilities which should really fall to the user.

Yours very truly,

B. C. SWINEHART,

Sales Manager Motor Truck Department, Republic Rubber Company.

Youngstown, O., April 2.

SHOULD MAKERS GUARANTEE THEIR PRODUCT?

WHILE prospective purchasers of industrial transports naturally are interested in the subject of guarantee, it is possible that they fail to consider the manufacturer's side of the proposition. The accompanying communication gives the opinion of at least one maker on this point:

Editor, MOTOR TRUCK,

Sir:

Today the buyer of a motor truck has every advantage in the way of guarantees. The present extremely high costs of motor truck manufacture are brought about largely by the unreasonable demands made by owners and operators. This, of course, is not applicable to all users, for there have always been some reasonable operators, and many are beginning to realize the advantages to be derived from dealing with the truck manufacturer who is producing a first class truck and who, by good business methods, is making a fair return on his investment and will, therefore, stay in business. They can see how a short-time guarantee by this maker is better than a guarantee of two, five or seven years by less conservative, conscientious and businesslike makers. No first class manufacturer of motor trucks will refuse to replace a defective part, if that part be sent to him for inspection, irrespective of any guarantee he may have placed on it.

The commercial vehicle convention in March after careful consideration of the situation, recommended a 90-day guarantee. This does mean that no maker will replace any defective part which may show up six months after delivery, but was adopted for the protection of the manufacturer against unscrupulous users. The time will come when guarantees will be eliminated as unnecessary. Until then, the manufacturer should insist upon the user paying at least for his education instead of continually standing the brunt of it and paying for it himself.

Experience has shown that one of the great troubles has been to convince the buyer of the type of truck he should purchase. If a study of his business showed conclusively to the manufacturer that the buyer should install two-ton trucks and the buyer absolutely insisted that one-ton trucks were of ample size, the manufacturer rather than lose the business, has sold them, with disastrous results. The blame for all failures was invariably placed upon the manufacturer. The user claimed that the trucks were too light and would not stand the work, when the truth is they were overloaded. Had he installed the heavier model, the user would have had satisfaction from the start.

The manufacturer lays down certain rules of proper care, and specifies carrying capacities and maximum speed limits, which if exceeded will result in withdrawal of the guarantee. No attention is paid to these, but if the manufacturer does not help the user out of trouble he has gotten himself into he threatens to trade his trucks for some other make. To the serious detriment of the truck industry at the present time, too many manufacturers are abetting this sort of thing.

Some of the highest costs of truck manufacture are brought about because the truck maker has not only to provide the finished truck, but must bear all the burden of expense in teaching the operators, often even providing the drivers. He must either become an expert on transportation, or hire one and furnish his services free of cost to the customer, who wants an insurance against any possible loss and asks for all sorts of guarantees which are absurd on their face and which he does not get in any other line of business.

Now, why should not the purchaser, who is to be the great gainer, be willing to pay at least for his education? There is nothing that can be done by horses in merchandise delivery that cannot be done faster and more economically by motor trucks, but as the trucks should be handled and treated in a different way from horses, the motor truck manufacturer should certainly be protected if the purchaser insists on handling the truck his own way. Every truck maker who is giving long-time guarantees is, I am convinced, showing a weakness in his product, because his policy proves that he is selling his machines on promises and not on their quality.

Speed governors should be installed on all trucks. It is important that they should be accurate and really govern, holding the number of revolutions of the motor down to a certain given point. However, the governor will not control a truck coasting down long grades and it can often be tampered with by experts without the knowledge of the manufacturer. To overcome this, every truck should be equipped with a speedometer that has a maximum hand or a recorder, which should be sealed or locked and the key kept by the owner. This will show the highest speed attained at any time with the truck. If a fine were charged against the driver for exceeding a certain speed limit, and dismissal were to follow the second fine, 90 per cent. of the present truck troubles would disappear. The song that was written several years ago entitled, "It is not the miles we travel but the pace that kills," should be applied to motor trucks and sung all over the land.

Last of all, tire manufacturers should take an absolute stand against overloading and report every case that comes to their attention to the owner of the truck and to the manufacturer. Above all, they should insist on the use of tires of sufficient size for the load capacity, which they can back up with their guarantees, but they should be perfectly impartial to all truck manufacturers and not give one an advantage over others, which, at the present time, they are doing in many cases.

Every assistance should be given the National Association of Automobile Manufacturers that is devoting so much time to the motor truck industry in an effort to establish a perfectly equitable basis on which to do business.

Yours very truly,

B. A. GRAMM,

Vice President, Gramm Motor Truck Company.

Lima, O., April 4.

MILLER'S NEW CATALOGUE.

The 22nd annual catalogue of Chas. E. Miller, 97-103 Reade street, New York City, is ready for distribution to such as make application for it. It is a neat and attractive volume, comprising 256 pages of information concerning all of the latest and most approved equipment and supplies for motor cars, motor boats, motorcycles and motor planes. Owners and users of commercial vehicles will find this a decidedly valuable book, particularly as a work of reference when in need of parts or fittings.

As is more or less well known, Chas. E. Miller is the pioneer supplies dealer in the automobile industry. "Try Miller" has become an accepted trade term, as applying when it is impossible to secure the needed accessory elsewhere. As importer, exporter, manufacturer and dealer, this house has gained a world wide reputation, and has 15 branches located in nine states throughout the country.

Inasmuch as the firm was established in 1896, it is not at all strange that the 22nd annual catalogue should prove a veritable index of the accessory and supply business. The owner of a motor truck will be surprised to find listed therein practically every product of note produced in America or abroad. It also will be found that several new things have been added, and the fact that Chas. E. Miller indorses them is sufficient guarantee of their worth.

BRIEF NEWS OF MANUFACTURER AND THE TRADE

The Kadix Motor Truck Company of 6 Watson avenue, East Orange, N. J., has been incorporated for $100,000.

Green & Swett, Boston, will open a branch house at Manchester, Mass., having taken a lease of the Wonson building on Central street.

The Auto Tractor Company, Augusta, Me., has been incorporated for $100,000. L. J. Coleman is president and treasurer, and R. S. Buzzell, clerk.

The Goodyear Tire & Rubber Company, Akron, O., announces that its branch at Birmingham, Ala., is occupying its new quarters at 420-422 20th street.

The Federal Motor Truck Company, Pittsburg, Penn., has taken the agency for the Mais truck, made by the Mais Motor Truck Company, Indianapolis, Ind.

James H. Paplo, 656 Bergen street, Brooklyn, N. Y., has taken the agency for the Packers truck, made by the Packers Motor Truck Company, Wheeling, W. Va.

The Velie Motor Vehicle Company, Moline, Ill., has appointed Fred E. Bradfield, formerly connected with the Chicago branch, as manager of the branch at Boston.

The Pope Manufacturing Company, Hartford, Conn, is contemplating the erection of a four-story addition to its plant, furnishing 60,000 additional feet of floor space.

The Steinbock Engineering Company, Edgewater, N. J., has been incorporated for $1,000,000. The incorporators named are E. J. Forhan, F. B. Knowlton and J. McLaren.

The Worcester Automobile Parts Company, Worcester, Mass., has been organized and incorporated for $10,000. James N. Heald is president and treasurer; Cyrus A. Cowan is clerk.

Albert Bale, Hinckley, Ill., has been appointed agent of the Velie line and will have territory including DeKalb, Lee, Ogle and Kane counties. He will maintain a service station.

The Punctureless Tire Company of Massachusetts, Boston, has been incorporated for $15,000. The incorporators include William E. Riddell, J. Hiram Smith and Frank H. Jenkins.

The Dennis Motor Company, Toledo, O., has been incorporated for $25,000, the incorporators including H. H. Dennis, G. W. Close, Allen E. Reid, R. S. Woodrow and J. C. Meister.

The Alpha Rim Company, Brooklyn, N. Y., has been incorporated for $100,000 to manufacture motor car rims. The incorporators include C. M. O'Donnell, G. H. Tice and M. P. Bau.

The Automobile Repair & Sales Company, 913 North Broad street, Philadelphia, has taken the agency of the Sandusky line, made by the Sandusky Auto Parts & Motor Truck Company, Toledo, O.

The Union Machine & Gear Company, Boston, has filed notice of incorporation with a capital of $25,000. The directors include William L. Thompson, James O. Horne and George C. Little.

The C. A. Scott Company has been organized at Portland, Me., with $10,000 capital and will deal in trucks and motors of all types. The officers include: President, Hugh Lawson, and treasurer, Charles A. Scott.

Gray & Davis, Boston, Mass., has been incorporated for $1,250,000. The incorporators named include William Gray, Alexander Churchward, David B. Kerr, William B. Moses, D. Henry Elkins and William H. Gray.

The Bessemer Motor Truck Company, Grove City, Penn., has established a Boston branch at 903 Boylston street, which will be in charge of Robert G. Howard, who for many years was identified with the Autocar Company.

Robert Kayser, formerly connected with the Boston branch of the Velie Motor Vehicle Company, Moline, Ill., has accepted a position at the Chicago branch of the company. George D. Anderson, formerly with the Haynes Company, is now with same branch.

Ford Dealers of Grand Rapids, Mich., Who Recently Visited the Ford Motor Company at Detroit, Where the Plant Was Inspected and the Party Was Entertained by the Executives of the Company.

Johnson Martin, manager of the South American division of the General Motors Export Company, is on his way to Buenos Ayres, where he will establish headquarters for the G. M. C. line of gasoline and electric vehicles.

Perkins & Corliss, agent at Gloucester, Mass., for the White line, made by the White Company, Cleveland, O., has placed a White truck with the Presson Express Company of that city. The body and top will be of special design.

The Standard Auto Renting Company, New York City, has filed notice of incorporation. Its capital is $10,000 and the incorporators include David C. Goodman, William Machol and Edwin B. Koenig, the latter of 1190 Madison avenue.

Thompson Bros., San Francisco, Cal., has taken the agency in northern California for the Johnson trucks, made by the Johnson Service Company, Milwaukee, Wis. The new concern plans the erection of a garage and service station.

The Peerless Motor Car Company of New England announces the opening of a branch and service station at 773 Broad street, Providence, R. I., which will be in charge of J. W. Breese, a factory representative

Section of the Assembly Room of the Lippard-Stewart Motor Car Company, Buffalo, N. Y., Depicting a Fleet of Commercial Vehicles Being Made Ready for the Road.

The Findeisen & Kropf Manufacturing Company, Chicago, has secured the Hall Motor Supplies Company of Toronto, Can., as its Canadian distributor of the Rayfield carburetor, also the R. C. Hull Electric Company, Cleveland, O., to represent it in that terrtiory.

The Postles-Prouse Company, Wilmington, Del., has been organized to take over the business formerly conducted by Col. Postles. The officers are: President, G. P. Postles; vice president and general manager, Shanley D. Prouse; secretary and treasurer, John H. Willit.

The International Motor Company, New York City, maker of the Mack, Saurer and Hewitt lines, has opened offices in the Candler building, Atlanta, Ga., making this city headquarters for the Southeast. It is proposed to establish a southern branch and service station in the near future.

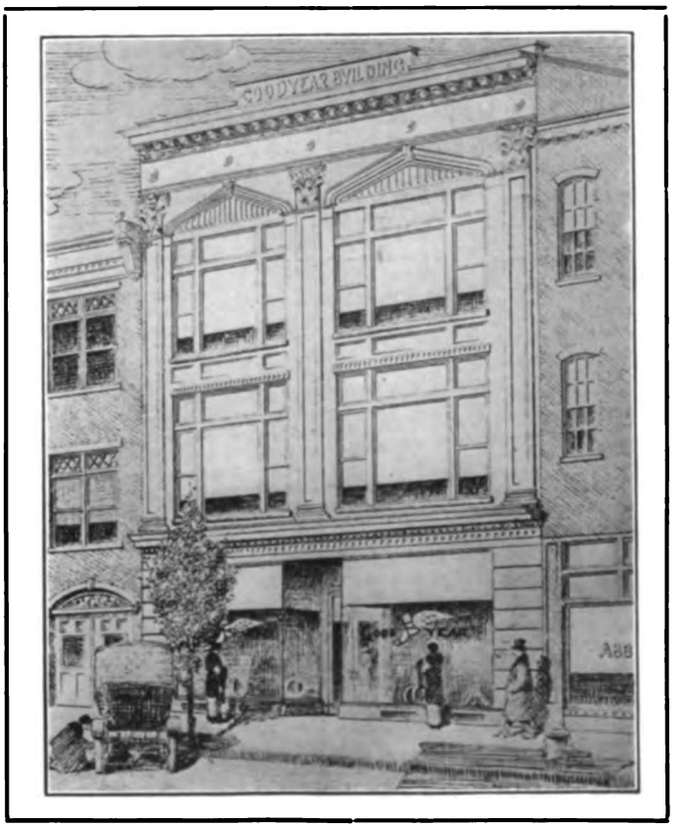
The Standard Woven Fabric Company, Worcester, Mass., maker of Multibestos, has increased its selling branches, having closed with Petry-Cassidy, Inc., 1416 Vine street, Philadelphia, as agent in Pennsylvania and the South, also James G. Barclay, 720 Main street, Buffalo, N. Y., who will act as sales agent through central and western New York State.

The Blood Bros. Machine Company, Kalamazoo, Mich., maker of universal joints, is running its plant night and day in order to take care of its increasing business. Several new additions to the factory were made and new machinery installed last summer, but even with the capacity for its output doubled additional structures are expected in the near future.

The Atterbury Motor Car Company, Buffalo, N. Y., has established headquarters for its product at 19 Hoadley place, Hartford, Conn. The company will be known as the Atterbury Motor Truck Company of Connecticut and will have subagencies in New London, New Haven and Waterbury. Edward J. Ives is manager, and R. K. Swett joined the sales force recently.

The New York Lubricating Oil Company's business has grown so rapidly during the last year, especially on the Pacific Coast, that it has been found necessary to open a branch office at Seattle, Wash., at the corner of Virginia and Railroad avenues. A larger warehouse has also been opened in Newark, N. J., the address of which hereafter will be 3739 New Jersey Railroad avenue.

The Lippard-Stewart Motor Car Company, Buffalo, N. Y., announces that the following concerns and individuals are handling its line of commercial vehicles: Sterling Place Garage, Brooklyn; Newark Power Wagon Company, Newark; Ryder Motor Company, Poughkeepsie, N. Y.; W. H. Heinzerling, Sedro-Woolley, Wash.; Turk & Brown, Rochester, N. Y.; Dean DeWitt, Columbus, O.; Neely & Ensor, Baltimore, Md.; Edwin Jennings Company, Bridgeport, Conn.; Michigan Motor Company, Portland, Ore.; The Whitten Motor Vehicle Company, Providence, R. I.



The Ford Motor Company, Detroit, entertained another large delegation of Ford dealers recently and the accompanying illustration presents the party which was photographed after breakfasting at one of the prominent hotels, where the members were guests of the company. An inspection of the plant followed, after which the party lunched at the Log Cabin Inn with the executives of the company. N. A. Hawkins, manager of the commercial department, addressed the agents upon facts pertinent to the mechanical transport, and he also acted as toastmaster at a banquet in the evening. The visitors departed shortly after midnight on a special train for Grand Rapids, Mich.

The Auto-Suburban Company, Ltd., St. Johns, N. B., has filed notice of incorporation. The capital stock is $9990 and the incorporators include J. Fraser Gregory, Clarence B. Allen, John H. Kimball, Harley Knox, Dr. J. Herbert Barton, Dr. Horace C. Wetmore, A. Ernest Everitt, William C. Rothwell, Harold A. Allison, F. J. Likley and William McLaughlin. The company proposes to establish automobile service between Scott's Corners and Millidgeville.

The American Locomotive Company, New York City and Providence, R. I., has appointed the following agents: H. H. Dennis, Toledo, O.; T. A. Crow, Toronto, Canada; Franklin Auto & Supply Company, Milwaukee, Wis.; Park Auto Company, Erie, Penn.; Auto Sales Company, San Francisco, Cal.; Guy R. Champlin, Jacksonville, Fla.; Augustus E. Staley, Decatur, Ill.; William J. Mehring, Harrisburg, Penn.; H. W. Brown, Binghamton, N. Y.; Peden Iron & Steel Company, San Antonio and Houston, Tex.; Levy-Kramer Automobile Company, Dallas, Tex.

The Lippard-Stewart Motor Car Company, Buffalo, N. Y., announces that Charles H. Dahlquist has been secured as assistant chief engineer. He has been engaged with the International Harvester Company for two years as chief engineer of the automobile business. Previous to that he occupied a similar position with the Velie Motor Vehicle Company. He is well known among automobile engineers as a man of unusual ability.

The Goodyear Tire & Rubber Company's Philadelphia branch is now located in new quarters at 207-209 North Broad street and is depicted in an accompanying illustration. The structure is three stories in height and its terra cotta front adds to its attractive appearance. The interior is unusually well lighted. In the arrangement of the basement, special thought has been given to motor truck tires, due to the rapid development of this industry. Spaces are provided for the storage of heavy steel bands, rims and other necessary equipment. The first floor is devoted to the show room, offices, salesrooms, ladies' retiring room, etc. The woodwork is of highly polished oak as are the furnishings The electric lighting system is similar to that utilized in the Chicago branch. In the rear of the salesroom is the adjusting department fully equipped for this work, also a ladies' retiring room for the use of touring customers. The shipping department is at the rear and from it, elevators lead to all floors. On the second floor is located the stock room for pleasure vehicle tires, these being carried in racks of the latest design.

New Home of the Philadelphia Branch of the Goodyear Tire & Rubber Company, Akron, O., Which Is Thoroughly Modern and Contains Every Convenience for Handling Tires, Etc.

Digitized by Google

MOTOR LINE TO HANDLE MILK.

The Belt Line Automobile Traction Company, operating between Ninevah, Edinburgh, Shelbyville and Blue Ridge, Ind., held a meeting recently and decided to make stops and pick up cream from farmers living along the route and deliver it to consumers in Shelbyville, the only provision being made was that the business shall warrant the stops. The company was organized last July.

TRANSPORT FUEL BY TRUCKS.

Among the large corporations replacing their horse drawn equipment with motor propelled vehicles is the Standard Oil Company of New York City which maintains a large number of branches throughout the country. The vehicles are employed to haul fuel oil which is carried in special tanks and in the accompanying illustration is depicted a type of truck utilized for this purpose. It will be noted that the chassis is fitted with special sills for the purpose of distributing the weight evenly and that access to the tank is by means of a ladder. When the containers are full the truck is subjected to considerable weight, but the many automobiles in service have demonstrated their ability to haul such loads easily as well as with decided economy over the horse drawn equipment. The machine illustrated is in service at Kansas City, Mo.

Type of Chassis Utilized by the Standard Oil Company for Transporting Oil Fuel at Its Numerous Branches.

TO EXPERIMENT WITH ENGINES.

What is termed a gasoline motor experimental station has been erected at the junction of the Rock Island and Denver & Rio Grande Railroad tracks in Roswell, Col. It is understood that the heaviest stockholder in the enterprise is Richard T. Robinson, Jr., who, with his father, is interested financially in the J. I. Case Threshing Machine Company, Racine, Wis. Edward Rorke is superintendent of the plant.

The recent announcement that the Case concern was about to engage in the production of commercial vehicles and the reported purchase of the Stephenson Motor Car Company, Milwaukee, Wis, by this concern, makes the new experimental station of more or less interest to the industry. The Stephenson company produces a line of mechanical transports, the name of which has been changed to Utility.

EXPRESS COMPANY ADOPTS TRUCKS.

The fact that the leading express companies are replacing the horse drawn equipment with the mechanical transport is attracting the attention of business men throughout the country, who realize that the express concerns have investigated the practical features of the automobile before adopting the more progressive form of transportation. An nouncement is made that the American Express Company has decided to place in service a number of trucks in Portland, Lewiston and Bangor, Me.

LEE TIRES GIVE BIG MILEAGE.

Pneumatic tires are utilized for commercial vehicles of certain carrying capacities and the Auto Car Service Company has been testing for some time past the Lee puncture proof shoe, made by the Lee Tire & Rubber Company, Conshohocken, Penn. Reports from the Philadelphia branch of the Auto Car Service Company show that 29 Lee tires have given a combined service of 153,903 miles, or an average of 5307 miles a tire without a puncture or a blowout.

VELIE TRUCK COST ESTIMATES.

In order that prospective purchasers of commercial vehicles may have a fair estimate of the operating expense of two and three-ton trucks, Morton H. Luce, manager of the Chicago branch of the Velie Motor Vehicle Company, Moline, Ill., has compiled a schedule of estimates. In these the machine is charged off at the end of seven years, and a very liberal allowance is made for upkeep as well as depreciation.

A. D. Frost has been appointed manager of the newly established Alco branch in New York City, and will have charge of the service building on Jackson avenue, Long Island City, N. Y. F. A. Crooks is assistant manager.

ADAMS TRUCK HAULS EXPLOSIVES.

Mechanical transports are utilized in many industries, but what is believed to be a new use for the automobile is that of hauling dangerous explosives in large quantities. The Independent Torpedo Company transports large quantities of nitro-glycerine from one state to another and until recently horses were employed in this dangerous work. These have now been replaced by an Adams truck, made by the Adams Bros. Company, Findlay, O., and in the accompanying illustration is presented the vehicle carrying 720 quarts of the highly explosive fluid.

The chassis is a regular stock production, the only extra equipment being Swinehart cellular non-skid tires. The regular body is lined with a pan, in which rests a special body having a number of compartments for holding the cans containing the explosive. This inner or special body is also equipped with a pan, which guards against the possibility of any of the fluid leaking into the mechanism of the machine should a can develop a leak.

DOELGER SELLS LAST HORSES.

Peter Doelger, the New York brewer, recently advertised for sale the last horses in his stables, and within 30 days the entire delivery service of the brewery will be by motor, electric trucks of the General Vehicle make being used mostly. When Mr. Doelger purchased his first motor truck three years ago, he was operating 70 horse trucks, and had 175 horses in his stables. He gradually disposed of the animals and substituted mechanical transports, his first experimental purchase proving a great success, and with the sale of his last horses he will be the first brewer to trust exclusively to motor trucks for all purposes. For utility work around the brewery yard, the General Vehicle Company of Long Island City, is designing a special wagon.

Mr. Doelger now uses 38 electric trucks, with 16 more ordered, and eight gas trucks, making a total of 62. The two-story garage which was erected last year is to receive three additional stories, giving it a capacity of 96 trucks, indicating that the present fleet of 62 is to be augmented considerably. While the garage will house 26 more trucks than were operated under the horse regime, the space it will occupy is much less, so much so that the demolition of the old horse stables will leave a space equal to 10 city lots for the extension of the brewery.

MOTZ TIRES IN MAIL SERVICE.

A light delivery motor car now makes the rounds of the mail boxes in Washington, D. C., the United States government having decided the success demonstrated in other fields is sufficient to warrant the adoption of the automobile in this work. The car shown in an accompanying illustration covers a distance of 105 miles a day, making 998 stops for the collection of mail. Conservatively estimating the number of horses it can replace at four, it readily can be seen what a big saving the new system means to the government.

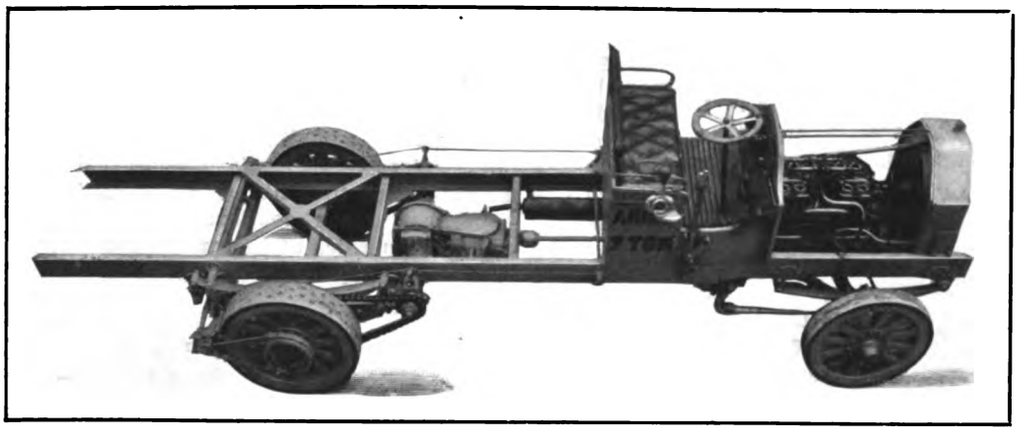
Mail Wagon Fitted with Motz Cushion Tires.

Service is expected regardless of roads or weather, and in this respect this little car has proved absolutely dependable. Probably one of the largest factors in delaying the adoption of the light quick delivery car for mail collection was the tire problem. The motor would not stand the shock of hard tires, and the question of pneumatics hinged upon the matter of expense.

In this instance the problem appears to have been solved through the use of the Motz high efficiency cushion tire, made by the Motz Tire & Rubber Company, Akron, O. This is held to be puncture proof and as resilient as a properly inflated pneumatic, the latter quality being due to the double treads, under-cut sides and slantwise bridges that characterize this make. These tires have given exceptionally good service on the mail wagon mentioned, and the maker claims that it is only a question of time when they will be adopted generally for this type of motor driven vehicle.

NEW ORLEANS WANTS TRUCKS.

The Sewerage and Water Board of New Orleans, La., is to have a motor equipment, bids having been asked for furnishing three machines, either two runabouts and one truck, or two trucks and one runabout.



Adams Truck in Service with the Independent Torpedo Company Hauling 720 Quarts of Nitro-Glycerine—The Vehicle Is Fitted with Special Body, Having Compartments for Carrying the Cans.

CONSTRUCTIONAL FEATURES OF ARIES TRUCK.

THE steel shod truck of France, is the slogan under which the Aries, made by the Aries Manufacturing Company of Villeneuve-la-Garenne, France, is being introduced to the American public by J. Jaccard & Co., 213 West 69th street, New York City. This implies much more than would appear from a casual rendition of the statement. Great emphasis is placed upon the steel tires, but equal force is applied to the statement that this is a truck from France. It is maintained that France is the mother country of the automobile and that it was in that country that the importance of the mechanical transport for heavy duty work was first realized. As a result it is claimed that the problem has been studied with an effort to realize durability and economy. Whether or not America is willing to concede this position, it must be granted that the designers of the Aries vehicle have paid special attention to detail, and as the Aries company has been manufacturing trucks for 16 years, it will prove of interest to examine the workmanship displayed in this seven-ton carrier.

The motor is a four-cylinder, four-cycle, water-cooled unit rated by the maker at 40 horsepower. The bore is five inches and the stroke 5.75. The location is in front under a hood, although this is subject to option, the maker following the Continental practise of placing the engine under the floor when it is so desired. In either case, full accessibility is provided, the mounting being on a special steel sub-frame, bolted against hard wood members which are in turn bolted to the side frame proper, permitting easy removal. In addition, it should be remarked that this form of suspension is designed to present a cushioning effect and completely eliminate all minor vibrations.

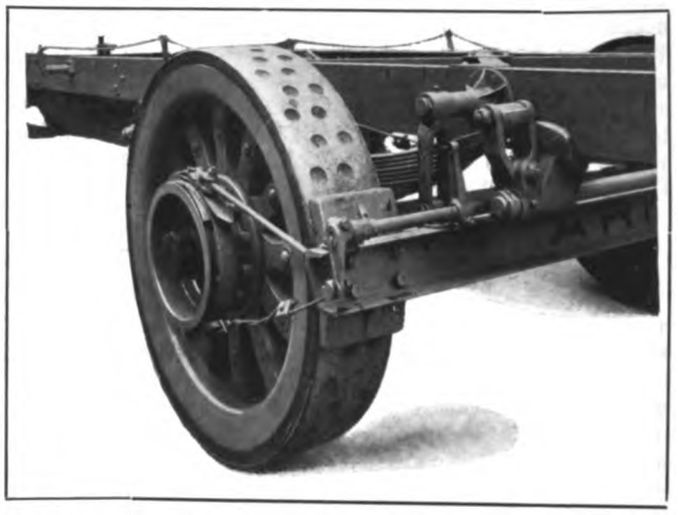
Semi-Plan View of Aries Chassis, Indicating Simplicity and Sturdy Construction.

While the subject of metal tires will be taken up later, it is worthy of note that the maker has realized fully the special strains, unusual conditions and excessive vibrations which must be overcome when these are employed, and as it has been engaged in studying this phase of the problem for the past seven years, the result of its experimentation is to be seen throughout the entire construction and assembly. For instance, the motor has been strengthened and stiffened at many points. The entire crankcase is made of steel, carefully designed and admirably proportioned, and despite its strength, it weighs but little more than aluminum castings of the usual construction. The base of the crankcase is carried up to the frame for the motor support, and a staunch cross member makes provision for the rear of the motor and flywheel.

The cylinders are cast in pairs of a special grade of material and arranged vertically. Valves are located on both sides of the cylinder head, being operated from two camshafts through the usual arrangement of valve lifters. Ample provision has been made for the ingress and egress of all gases, and all water, oil and gasoline pipes are large and substantial. Special care has been taken to provide liberal water jackets, which also surround the valve cages, thereby effectually cooling that portion of the cylinder which is subjected to the most severe heat. Small tubing or piping connections have been entirely eliminated and all joints have been given particular attention in order that there shall be no danger of these connections becoming disjointed or broken.

Ignition is by Bosch high-tension magneto, placed on the exhaust side. The carburetor is of special design, fool proof, automatic, and so constructed as to operate successfully with gasoline, benzol, naphtha or alcohol. This is located with the water pump on the inlet side. The lubrication system also is automatic, a pump being employed to force the oil through the crankshaft to all working parts of the motor. A sight feed on the dash informs the operator as to the condition of the supply at all times. The circulating water is kept in motion by means of a gear driven pump. An extra large radiator of the tubular type is mounted forward of the engine, cooling being aided further by a six-bladed fan directly behind this.

The clutch is the dry disc type, employing 39 discs, and alternating with bronze and steel. Adjustment is provided in the nature of a slight movement of a nut on a fine pitch screw. It is claimed by the maker that it requires absolutely no attention and performs its work in a highly satisfactory manner. The transmission is of the selective sliding gear type, affording three forward speeds and reverse. The whole transmission and differential is enclosed in a cast steel case, suspended at three points on the chassis in such manner that no deformation can affect the alignment. The ends of this casing extend to form shelves or bearings for the jackshaft, while the end of the right side is fitted with a projection forming an anchorage for the heavy working brake, the drum of which is in a recess at the side of the portion of the casing occupied by the differential. All gears are of nickel steel.



While on the subject of brakes, it may be stated that two sets are provided, one on the differential as explained, and the other acting on the rear wheels. These latter are of the external contracting type. They are so arranged that when the lever is operated, adjustable shoes are applied automatically to the surface of initial tires, as indicated by the accompanying illustration.

The frame is of the Longwy channel steel, strengthened by bars and cross sections. The springs are very long, strong and flexible, with swivel shackles and lubricating bearings. All are semi-elliptic. The forward members are attached firmly to the frame at one end and coupled by a swivel shackle at the other, while the rear members are shackled at both ends. This method of suspension is held by the maker to permit of free up-and-down movement without any warping or twisting of the spring plates themselves. In addition, it is claimed that the steel shod Aries

Digitized by Google

rides as easily as any other with rubber tires, by reason of the fact that flexibility of the suspension effectually absorbs all road shocks and much of the vibration.

The wheels are of the artillery wood type, but with the

Steel Tired Rear Wheel and Braking Mechanism on Aries Truck.

hubs supplied with unusually deep flanges, thus considerably increasing the sturdiness of the assembly. The spokes are made of a hard and fibrous wood, air dried by a natural process. Absolutely no kiln dried wood is used. The spokes are cut in conformity with the grain of the wood, so that the grain follows the straight line of the strains in them with accuracy. The whole is bound together by a specially constructed rim or felloe.

This latter is built up of small pieces of French elm, and each section is subjected to a thorough examination before being assembled. It is understood that the wood from which these are constructed is of such close grain, hard fibre and solid structure that it is one of the few woods which will not float in water. It is pointed out that this characteristic should convey some idea of the strength and strain-resisting qualities inherit in it.

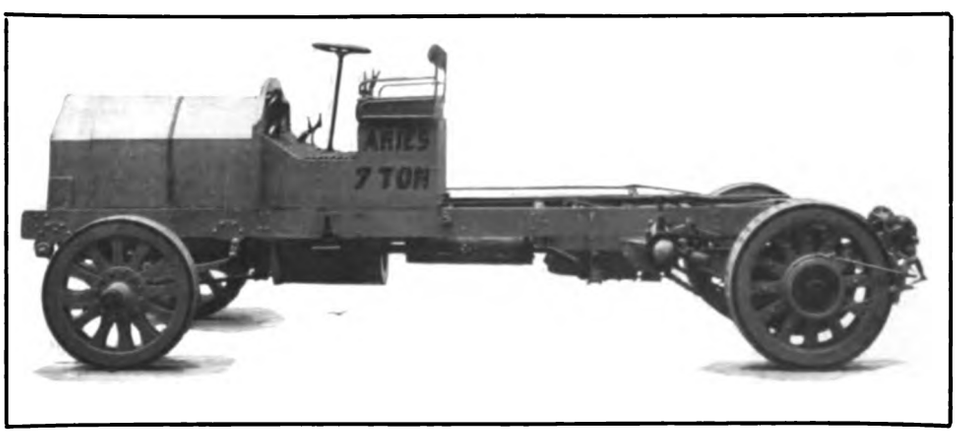
The Aries tires, for which so much is claimed, are made of Creuzot steel, which is held to possess the quality of being neither too hard nor too soft, and of being sufficiently tough to withstand constant hammering in service without cracking, and without stretching or expanding. It is held that when these are once placed on a wheel, they need no further attention.

Inasmuch as this particular brand of steel cannot be welded, the tires are cut from a solid billet, which has been brought to a predetermined heat, and a mandrill forced through the centre, thus leaving the billet in the form of a heavy washer. This is next placed in a special machine, and tapering mandrills are driven through the centre, expanding the whole and compressing the fibre of the metal which eventually is to form the tire. This operation is repeated, with heating between each operation, until the billet roughly assumes the shape desired, after which it is placed between two rollers and held under constant pressure. These proceed to roll the tire flatter and flatter, and at the same time still further compress the fibre, driving the molecules into closer relation with each other, until they are ready for the special hydraulic press. This consists of many hydraulic pistons placed radially around the rim of the wheel. These work in perfect unison and subject the rim to pressure uniformly throughout its entire circumference, and knead the steel tire into the wooden felloe. This operation is repeated 14 times, thus tightening the tire on the wheel, and each time with a new setting of the wheel in the machine, until wood and metal form one compact mass.

After the tire is firmly seated, binding the wheel under great pressure, the entire assembly is trued up on a lathe, thus insuring that both wheel and rim are absolutely concentric and perfectly centred. A conical hub is then inserted in the centre of the wheel, also by hydraulic pressure, insuring uniform radial strain on the spokes. This central hub tends to force the spokes outward against the inward pressure of the specially applied rims, and at all times the compression under which the spokes are held maintains the wheel absolutely true, circular, and free from warp or twist.

It is claimed that no Aries tires have ever been worn out in service, although many of them have covered great mileage, in some cases as high as 80,000 miles. The Aries company guarantees them for no less than 100,000 kilometers (60,000 miles). The company is prepared to furnish an extra rim fitted with rubber block tires for winter service, if desired.

MORE ROOM FOR TRACTORS.



Because of the increasing demand for its gasoline tractors, the Fairbanks Morse Company, Chicago, has decided to enlarge its present factory facilities at Beloit, Wis. The addition will be 80 by 130 feet. A new brass foundry also is being erected.

MOTORS TO COLLECT GARBAGE.

If the plans of the Knox Automobile Company of Springfield, Mass., are carried out, that city, which has had some trouble with its garbage disposal system, will collect garbage by motor trucks instead of by horse carts. A modern incineration plant is to be installed, and the feeling is that with this should go quicker and more modern methods of collection.

TRUCK LINE IN WISCONSIN.

A motor transportation service is to be placed in Sheboygan, Wis., to carry passengers and freight between that city and the towns in the vicinity. Local capital is interested, and the service is expected to solve to a great extent the problem of securing quick and inexpensive transportation facilities. Two 'buses for passengers and two trucks for freight will form the initial equipment of the line.

MORELAND COMPLETES TEST RUN.

A test run which will prove of more than ordinary interest was undertaken recently by Homer Crouch of the Moreland Motor Truck Company, Los Angeles, Cal., maker of the Moreland distillate truck. The vehicle was of two tons capacity and the run was from Los Angeles to Santa Barbara, a distance of 110 miles, which was accomplished at a cost of 71.5 cents for fuel and oil. Crouch was accompanied by C. H. Smith who acted as observer.

This proved to be the first time that a motor truck of this capacity had been over the road through Casitias pass, and in spite of the bad roads no trouble of any nature was experienced. Conditions were fair from Los Angeles to Calabasas, but soon after that point was reached a sand storm was encountered. The roads in the eastern portion of the pass were badly cut up and this section called for cautious driving. From the pass to Santa Barbara the surface was in excellent condition.

Upon its arrival in Santa Barbara, the machine was turned over to A. C. Grant, the local representative of the Union Oil Company, who had no hesitancy in accepting delivery when he learned how well the truck had performed on this trial trip. Another vehicle of the same make, but utilizing gasoline for fuel, will repeat the test, in order that more comparative cost figures may be obtained.

As has been stated the product of the Moreland Motor Truck Company is designed to use distillate, known as California No. 1, for fuel. This is vaporized in a float feed carburetor. The motor is of the four-cylinder, four-cycle, water-cooled type, with cylinders cast en bloc and arranged vertically. The bore is 4.125 inches and the stroke 5.25, giving a rating under the S. A. E. standard of 27.2 horsepower. Cooling is by centrifugal pump, gear driven, and by flat vertical tube radiator. Ignition is by Bosch magneto and dry cells.

The clutch is a cone member. The transmission is selective, affording three speeds forward and reverse. Final drive is by side chains. Two sets of brakes are fitted, contracting on jackshaft and internal expanding on rear wheels. The frame is of special alloy channel steel, hot riveted and with gusset plates on corners. Springs are semi-elliptic front and rear, with auxiliary springs over the rear axle. Tires are 34 by four-inch single, solid, in front, and 34 by three dual in rear. The wheelbase is either 10 or 12 feet, with tread in front 58 inches and in the rear 64.

BOSTON TRUCK ASSOCIATION.

The Boston Commercial Motor Vehicle Association held its annual meeting recently and elected directors as follows: C. F. Gilmore, agent for Federal and Dayton; A. P. Underhill, Knox; J. S. Hathaway, White; A. T. Fuller, Packard; L. B. Butler, G. M. C.; Day Baker, G. V. Mr. Baker was made treasurer, and Chester I. Campbell, the show promoter, secretary.

NEW G. M. C. CHASSIS.

The General Motors Truck Company, Detroit, has brought out a new underslung G. M. C. chassis, which is expected to allow loading and unloading of heavy materials with ease. This is accomplished by suspending the springs differently than with other models, and by bringing the chassis frame and body lower to the ground. The springs are placed under the axles, thereby gaining space taken by them in the standard construction. In addition to this, the frame is brought still lower, the side members being raised over the axles. This type of chassis will be made in the 3.5 and five-ton capacities.

COLLEGE COURSE IN TRUCK DESIGN.

The Rensselaer Polytechnic Institute of Troy, N. Y., is to establish a course in motor truck design. It will be very thorough in its work and will form a part of the regular mechanical engineering course, being given to students in the senior year. R. L. Streeter, assistant professor of mechanical engineering at the institute who advocated the course and secured its inclusion in the curriculum, will conduct it. Theory and practise will be covered, and the aim will be to enable the students to make a light, economical design which will have the greatest reliability.

SIX ROADSTERS FOR MILWAUKEE.

Milwaukee, Wis., has authorized the purchase of six roadsters at a cost of not more than $1000 each. They will be used by the six assistant chiefs of the fire department. The purchase was recommended by the fire and police committee, and the cars are to be bought in 30 days. It is expected that the department will be furnished with motor apparatus in the near future, though nothing definite has been done in the way of outlining the equipment needed. The fire department operates no motor apparatus at all beyond the chiefs' cars.

MAIL AUTO FOR SYRACUSE.

Syracuse, N. Y., is to have a mail automobile, the local postmaster having been authorized to purchase a car through one of the collectors. In a test made last fall a collector opened 65 mail boxes in 85 minutes, and covered 35 miles. With a horse the same trip took three hours. An allowance of $60 a month is made for maintenance.

RACINE'S CHEMICAL CAR.

Racine, Wis., recently purchased a chemical and hose car for use in the central station. It has a motor of 30 horsepower, and is capable of speeds up to 50 miles an hour. The fire department economized in purchasing the machine by fitting it up with equipment taken from a horse drawn chemical wagon.

'BUS SERVICE IN NEW HAVEN.

New Haven, Conn., which has not been quite satisfied with the automobile 'bus line running out Orange street, is to have a new company which will operate modern vehicles. The concern is being organized with a capital of $60,000, and the plans call for the purchase of six cars. One of the type which is to be bought was tried out on the route recently, and was found to ride much better and have more speed than the ones now in service.

CARS FOR THE CIRCUS PARADE.

The Herbert A. Kline Show, a circus with headquarters in Flint, Mich., is operating two Buicks in its parade. Both contain compressed air calliopes guaranteed to make as much noise as the steam variety with the usual economy that goes with motor operation. The circus is having a Cole car built specially for its use.

PITTSBURG BUYING MACHINES.

The city of Pittsburg, Penn., recently placed orders for six machines, three of which will be used by the police department as patrols, and three by the highways department for handling hot asphalt.
